A JOUI

VOL

Digitized by Google

Industries:

A Journal of Engineering, Electricity, & Chemistry

FOR THE

Mechanical and Manufacturing Trades.

VOL. VIII.—JANUARY TO JUNE, 1890.

Offices:

LONDON: 358, STRAND, W.C.

MANCHESTER: 70, MARKET STREET. GLASGOW: 93, HOPE STREET.

INDEX TO "INDUSTRIES."

Articles.

*(All Articles marked thus * are Illustrated.)*

Adams' Automatic Bolt Cutter, 234*
Adamson, The Late, Daniel, 63*
Admiralty Dynamo Specification, The, 350
Agricultural Show, Royal, 584*, 601*
Agricultural Show at Rochester, 568
Air Propeller, Verity's "Silent," 65*
Air Propellers, Sayer's, 257*
Allen, The Late Horatio, 111*
Allen's Pumping Machinery for the Japanese Government, 268*
Alloys, Notes on, 115, 236, 355, 409, 475
Alternating Circuits, Arc Lamps on, 498
Alternating Current Apparatus, Some Tests of the Efficiency of, 401*
Alternator, Mather & Platt's, 64*
Aluminium and its Uses, 410
Aluminium Process, The Heroult, 499*
America, Bridge for Central, 243*
America, National Electric Light Association of, 235
American and English Practice in Electrical Engineering, 254
American Institute of Electrical Engineers, 571, 594, 617
American Navy Proposals, 86
American Society of Engineers, 529, 556*
Anderson & Gallwey's 200-Ton Hydraulic Riveting Plant, 316*
Arbey's Tools at the Late Paris Exhibition, 97*, 176*, 228*, 265*
Arbitration among Scotch Miners and Paper-makers, 86
Arc Lamps on Alternating Circuits, 498
Architects' Registration Bill, 351
Arnold's Steam Boiler, 416*
Aron Electric Meter, The, 139
Arrol on Labour Questions, Sir William, 230
"Audio" Telephone Mouthpiece, 473*
Austin's "Infant" Dynamo, 572*

Bailey-Friedrich Steam Motor, 112*
Baines, The Late Sir Edward, 230
Baker's Biscuit Making Machinery, 368*
Band Saw Machines for Heavy Timber, 217*
Band Saw Machine, Watts' Double, 461*
Barlow & Jones v. Johnson & Co., 256
Barraclough's Wire Covering Machine, 121*
Barraclough's Wire Straightening Machine, 5*
Bath, Electric Lighting at, 616
Battery, Weymersch Primary, 234, 616
Bending Moment Delineator, 484*
Benest's Submarine Grapnel, 424*
Bennerley Furnaces, Boiler Explosion at, 128
Bennett & Sayer's Brick Making Machines, 145*
Bennie's Large Lever Punching Machine, 84*
Bent's Tool Holder, 464*
Berlin Labour Conference, The, 349
Biggs' Tubular Lock, 496*
Biscuit Making Machinery, 368*
Board of Trade and Electric Lighting, 546, 594, 617
Board of Trade Rules on Life-Saving Appliances, 329, 351
Boiler, Arnold's Steam, 416*
Boiler Explosion at Bennerley Furnaces, 128
Boiler Explosion at Dudley, The, 400*
Boiler Flue, Farnley, 15*
Boiler Flues, Midgley's, 128*
Boiler Legislation, Steam, 37
Boilers, Evaporation in Lancashire, Paper read by M. Longridge before the Manchester Association of Engineers, 98*
Boilers, Grate for Vertical, 196*
Boilers, Marine, Paper read by Mr. C. B. Casebourne before the North-East Coast Institute of Engineers and Shipbuilders, 18*
Bolt Cutter, Adams' Automatic, 234*
Boring and Drilling Machine, Horizontal, 156*
Boult's Cylinder Lubricant Tester, 149*
Boult's Tricord Light Adjuster, 185*
Brakes, Continuous, Paper read by G. Kiernan before the Manchester Association of Engineers, 207
Brebner, The Late A., 255
Brick Making Machine, 137*, 145*, 185*
Bridge Erection in Glasgow, Rapid, 567
Bridge for Central America, 243*
British Association, The, 518
Budget, The, 397
Buenos Ayres, Exhibition at, 296*
Burnham's Steam Loop, 601*
Burns, The Late Sir George, 543
Butler's Domestic Petroleum Engine, 464*

Cables, Insulation Resistances of, 544
Canal, Forth and Clyde, 132
Canal, Japanese, 80*
Canal, Manchester Ship, Progress during 1889, 32
Canal, Suez, 588
Candle, Devonshire's Everlasting, 348*
Cardew's Earthing Device, 379*
Carlisle Railway Accident, 470, 494
Carter's Road Wheel, 457*
Cartridge, Mullineux's, 8*
Cellulose and its Constitution, 19
Cement from Slag, Manufacture of Portland, 402*
Cements and Weight Saving in Ship Structures, Protective, 147
Channel Tunnel, The, 77,
Chapman's Quadruple Evaporator, 148*
Charlesworth, Hall, & Co.'s Dynamo, 304*
Charlottenburg Testing Station, The, 425
Chelmsford, Electric Lighting at, 374
Chemical Industry, Society of, 44, 139, 403, 548; Manchester Section, 67, 164, 259, 355, 476; Liverpool Section, 186, 260, 356; Glasgow and Scottish Section, 186, 260, 356, 500, 572; Newcastle Section, 68, 164
Chemical Progress in 1889, 50
Chemical Society, The, 620
Chimney Shafts from Lightning, Protection of, 289
Chimney Shafts, Straightening, 195
China, Cotton Mills in, 327
China, Difficulties of Foreign Enterprise in, 39
China, Opening of Western, 254, 326
Chinese Railways, 109
"Chiyoda," Japanese Cruiser, 540
Chlorine Processes, Nitric Acid, 404
"City of Rome," Accident to the, 567, 588*
"City of Paris," Breakdown of the, 320, 348, 374, 615
Civil Engineers, Institution of (see Engineers, Institution of Civil)
Cleathero & Nichols' Apparatus for Feeding Printing Machines, 378*
Cleveland Institution of Engineers, 135
Clyburn Spanner, Improved, 588*
Clyde and Forth Canal, 132
Clyde Shipbuilding, 159, 234, 396, 512, 584
Clyde, Tunnel Under the, 149
Coal Cargoes, Spontaneous Ignition of, Paper read by Professor V. B. Lewes before the Institution of Naval Architects, 386
Coal Crisis, The, 279
Coal Fields of the Transvaal, 296
Coal in Kent, 182, 195, 280
Coal, Iron, and Cognate Industries, 63, 159, 272
Coal Supply, Duration of Our, 61
Coats, The Late Sir Peter, 255
Coke Crusher, Welch's, 553*
Colliery Engines, Semi-portable, 252*
Commerce and Industries during 1889, 1
Commercial Education, 156
Commercial Morality, 158
Condensation and Re-evaporation in Marine Engine Cylinders, 326
Conductors by Electric Currents, Heating of, 185*
Conley-Lancaster Process for Extracting Iron from Ore, 522
Co-operation, Lord Rosebery on, 518
Copper in 1889, Prices of, 40*
Cotton Industry, The, 398
Cotton Mills in China, 327
Crane, Spencer's Travelling, 248*
Crompton & Co. *v.* Eliesen Electric Lighting Company, 568
Crompton's Four-pole Drum Dynamo, 396*
Crooks, Roberts, & Co.'s Slotting Machine, 481*
Cruiser "Chiyoda," The Japanese, 540
Cruiser "Latona," Her Majesty's, 492*
Cruiser "Newark," United States, 440*
Cruiser "San Francisco," United States, 8*
Crushing Machine, The Fulton Ore, 409*
Crushing Mill, The Lamberton Ore, 516*
Cycle Show, The Stanley, 104

Daimler's Petroleum Engine, 553*
Deptford Central Electric Lighting Station, 618*
Devonshire Everlasting Candle, The, 348*
Dock Improvements at Liverpool, 560*
Dockyards during 1889, Work in the Royal, 73
Dodman's Horizontal Engine, 75*
Downie's Packing Rings, 73*
Downing's Grate for Vertical Boilers, 196*
Drains, Gradient Indicator for, 128*
Draught, Progress of Forced, 158
Drilling and Boring Machine, Horizontal, 156*
Drilling Machines for Large Boiler Shells, 300*
Drilling Machine, Parkinson's, 416*
Drilling Machine, Radial, 196*
Drilling Machine, Sensitive, 433*
Drilling Machine, Wall-bracket Radial, 344*
Drilling Machines, Herbert & Hubbard's, 289*
Dudley, Boiler Explosion at, 400*
Dutton's Oil Measuring Pump, 497*
Dutton's Signal Lamps, 608*
Dynamine, Lubricator for, 224*
Dynamo and Engine, Smit's Combined, 348*
Dynamo, Austin's "Infant," 572*
Dynamo, Charlesworth, Hall, & Co.'s, 304*
Dynamo, Crompton's Four-pole Drum, 396*
Dynamo, Mather & Platt's Alternating Current, 64*
Dynamo Specification, The Admiralty, 350
Dynamo, Wenström's, 281*
Dynamos and Motors, Graphic Construction for, 42*, 90*, 114*, 138*

Earthing Device, Cardew's, 379*
Edinburgh Exhibition, 44*, 320, 400*, 423, 440*
Edinburgh Exhibition, Electric Lighting at the, 440*, 536*
Edinburgh Exhibition—Prime Movers, I., 488*, 512*
Edinburgh Underground Railway, 206, 615
Education, Commercial, 156
Education Prevent Strikes? Can an Improved, 469
Electric Currents, Heating of Conductors by, 185*
Electric Lamps, The Physics of, 185
Electric Light Association of America, The National, 235
Electric Light Regulations, 86
Electric Lighting at Bath, 616
Electric Lighting at Chelmsford, 374
Electrical Lighting at New York, 19
Electric Lighting at the Edinburgh Exhibition, 440*, 536*
Electrical Lighting Station, The Deptford Central, 618*
Electric Lighting, The Board of Trade and, 546, 594, 617
Electric Locomotive for Mines, 209*
Electric Meter, The Aron, 139
Electric Supply Stations at Paris, 355
Electric Switch, Double-pole Tramway, 115*
Electric Traction, The Waller-Manville System of, 448*
Electric Tramcar, Jarman's, 519
Electric Tramway, Lineff's, 616
Electric Welding Process, The, 616
Electrical Distribution, Safety in, 258, 281
Electrical Engineering, English and American Practice in, 254
Electrical Engineering in 1889, Progress of, 49
Electrical Engineers, American Institute of, 571, 594, 617
Electrical Engineers, Institution of (see Engineers, Institution of Electrical)
Electrical Subways in New York, Practical Working of the, 259, 282, 306, 330
Electricity as a Hastener in the Tanning of Hides, 498
Electricity versus Gas, Presidential Address by J. West before the Manchester Association of Engineers, 56
Elliott's Smoke Annihilator, 616
Emperor of Germany and the Labour Question, 157
Engine and Boiler, The Bailey-Friedrich Combined, 112*
Engine and Dynamo, Smit's Combined, 348*
Engine Cylinders, Condensation and Re-evaporation in Marine, 326
Engine, Development of the Steam, 229
Engine, Dodman's Horizontal, 75*
Engine, Richardson's Compound High Speed, 425*
Engine Trials, Research Committee on Marine, 544*, 553*, 577*
Engine, Triple Expansion Mill, 123*
Engineering in Italy, 542
Engineering Progress in 1889, 25, 32, 41, 49
Engineering Society, The Liverpool, 612
Engineers, American Institute of Electrical, 571, 594, 617
Engineers, American Society of, 529, 556*
Engineers and Shipbuilders, North East Coast Institution of, 18*, 249
Engineers, Cleveland Institution of, 135

192993

Digitized by Google

Engineers, Federated Institution of Mining, 139, 423
Engineers in the Navy, Appointment of Assistant, 398
Engineers, Institute of Marine, 207, 248, 280, 351, 468, 492
Engineers, Institution of Civil, 75, 136, 183, 257, 296, 344, 376, 496, 555
Engineers, Institution of Electrical, 66*, 89*, 112, 162*, 209, 234, 283, 305*, 331, 379, 473*, 497, 521, 546
Engineers, Institution of Mechanical, 111, 122, 169*, 219*, 433, 544*, 553*, 577*
Engineers, London Association of Foremen, 248, 280
Engineers, Manchester Association of, 56, 98*, 207, 353
Engineers of Japan, Institution of, 614
Engineers, Society of, 176, 224, 588
Engines and Boilers of the s.s. "Prins Willem II.," 409*, 433*
Engines for Collieries, Semi-Portable Hauling, 252
Engines, Horse-Power of Marine, 421
Engines of the s.s. "Friesland," 33*, 64
Engines of the s.s. "Stuttgart, 52*
Evaporator and Feed Water Heater, Morison's, 472*
Evaporator, Chapman's Quadruple, 148*
Euphrates, Navigation of the, 509
"Exact" Governor, Schaeffer & Budenberg's 42*
Explosion at Bennerley Furnaces, Boiler, 128
Explosion near Dudley, Boiler, 400*

Farnley Boiler Flue, 15*
Feed Water Heater, Morison's Evaporator and, 472*
File, Howarth's Tri-cut, 224*
Finsbury College, Technical Education at, 530*
Flax Scutching Machine, Spiegelberg's, 612*
Flue, Farnley Boiler, 15*
Flues, Midgley's Boiler, 128*
Forge at West Hartlepool, Gray's New, 97*
Forth and Clyde Canal, 132
Forth Bridge, 17*, 40, 88, 110, 200*, 205, 231, 232, 273*
Forth Bridge, Testing the, 88
Fox Patents, The Lane, 473
France and England, Communication Between, 541
French Exhibition, 497
Friction and Lubrication of Cylindrical Journals, Paper read by Professor J. Goodman before the Manchester Association of Engineers, 353
"Friesland," Engines of the s.s., 33*, 64
Fulton Ore Crushing Machine, The, 409*
Furnace, A New Form of Siemens, 75*
Furnace, Meldrum's Breeze, 580*

Gas, Detection of Water, 211
Gas Engine and Pump, 485*
Gas Generator, Thwaite's "Simplex," 330*
Gas Retorts, Yeadon & Adgie's, 426*
Gas, Steenberg's Water, 306*
Gas versus Electricity, Presidential Address of J. West before the Manchester Association of Engineers, 56
Gesner's Rust-Proof Process, 451*
Girard Hydraulic Railway, The, 352*
Glasgow and District Subway, Proposed, 39
Glasgow, Rapid Bridge Erection in, 567
"Globe" Separator, The, 513*
Glycerine, Examination of Commercial, 115
Godfrey Printing Machine Company's Gripper Platen Printing Machine, 337*
Gold Chlorination Processes, 450
Gold Extracting Process, Pollok's, 161*
Governor, Schaeffer & Budenberg's "Exact," 42*
Gradient Indicator for Drains, 128*
Grapnel, Benest's Submarine, 424*
Grate for Vertical Boilers, 196*
Gray, The Late Thomas, 279
Gray's New Forge at West Hartlepool, 97*
Gunboat, A French Submarine, 416
Gunboats for the Zambesi, 464, 540*
Gunpowders, Smokeless, 547
Gymnote, The French Submarine Gunboat, 416

Halske, The Late J. G., 303
Hartlepool, Gray's New Forge at West, 97*
Haseley Tedder, The, 584*
Heating of Conductors by Electric Currents, 185*
Herbert & Hubbard's Drilling Machines, 289*
Heroult Aluminium Process, The, 499*
Hetherington's Boring and Drilling Machine, 156*
Hetherington's Plate Planing Machine, 132*
Hetherington's Wall-bracket Radial Drilling Machine, 344*
Hirn, The Late Gustav, 135
Housing Gear for Rolling Mills, Jardine's, 458*
Howarth's Tri-cut File, 224*
Hudson Tunnel at New York, 508*
Hughes & Lancaster's Low-pressure Compressed Air Tramcar, 267*
Hungary, Metals and Machinery in, 580

Indiarubber, The Future Supply of, 187
Indicator, Steam Engine, Paper read by C. F. Budenberg before the Owens College Engineering Society, 152*
Industrial League, Irish, 14
Industrial Outlook, 253
Industries and Commerce during 1889, 1, 25, 41, 49
Inglis, The Late William, 398
Insulation Resistances of Cables, 544
Irish Industrial League, 14
Iron and Steel, Chart Showing Variation of Prices during 1889, 68*
Iron and Steel, Critical Points of, Paper read by M. Osmond before the Iron and Steel Institute, 481*, 493, 505*
Iron and Steel Institute, 446, 458, 481*, 505*
Iron, Coal, and Cognate Industries (see Coal, Iron, and Cognate Industries)
Iron from Ore, The Conley-Lancaster Process for Extracting, 522
Iron, Manufacture of Basic Pig, Paper read by H. Pilkington before the South Staffordshire Institute of Iron and Steel Works Managers, 337
Ironmongers' Exhibition, 290
Italy, Engineering in, 542

Jacket, Experimental Value of Steam, 579
Japan, Affairs in, 518
Japan, Foreign Trade of, 590
Japan, Institution of Engineers of, 614
Japan, Our Treaties with, 542
Japanese Canal, A, 80*
Japanese Cruiser "Chiyoda," 540
Japanese Exhibition, 1890, 280*, 577
Japanese Government, Pumping Machinery for the, 268*
Japanese Treaty Revision, 135
Jardine's Housing Gear for Rolling Mills, 458*
Jarman's Electric Tramcar, 519
Johnson's Brick-making Machines, 137*, 185*
Joule Memorial, International, 87
Joule, The Scientific Work of, 110
Journals, Friction and Lubrication of Cylindrical, Paper read by Professor J. Goodman before the Manchester Association of Engineers, 353

Kane, The Late Sir Robert, 206
Kent, Coal in, 182, 195, 280
Knight's Direct-acting Hydraulic Pumping Engine, 392*
Kuhlmann's Testing Machines, 52*

Labour Conference, The Berlin, 349
Labour Movements on the Continent and at Home, 373
Labour Question, Emperor of Germany and the, 157
Labour Question, Sir William Arrol on the, 230
Lamberton Ore Crushing Mill, 516*
Lamp Cleaning Machine, 581*
Lamps, Dutton's Signal, 608*
Lane Fox Patents, The, 473
Lathe, Shepherd, Hill, & Co.'s Tyre Turning, 605*
Lathe, The "Lukin," 193*
"Latona," Launch of H.M.S., 492*
Lead in the Water Supply of Northern Towns, 187
League, Irish Industrial, 14
Legal Proceedings: Barlow & Jones *v.* Johnson & Co., 256; Morgan & Co. *v.* Windover & Co., 327; Crompton & Co. *v.* Eliesen Electric Lighting Co., 568; Oakey *v.* Flatau, 591
Leeds Exhibition, The, 416
Legislation and Industry, 133
Legislation in 1890, Industrial, 302
Liability Bill, Employers', 374
Life Saver, Manwell's Ready, 581*
Life Saving Appliances, Board of Trade Rules on, 329, 351
Life Saving Appliances, New Rules for, 180
Light, The Present Standard of, 181
Light Adjuster, Boult's Tricord, 185*
Lighting, Electric (see Electric Lighting)
Lighthouse Illuminants, 446
Lightning Conductors from a Modern Point of View, 570
Lightning, Protection of Chimney Shafts from, 289
Lineff's Electric Tramway, 616
Lister's Screwing Machine, 569*
Liverpool, Dock Improvements at, 560*
Liverpool Engineering Society, 612
Lloyd's Committee of Shipbuilding, 252, 423
Lloyd's Register of Shipping, 134
Load Line Act, The, 613
Load Line Bill, The Compulsory, 230
Lock, Biggs' Tubular, 496*
Locomotive for Mines, Electric, 209*
Locomotive, Worsdell's Compound Passenger, 28*
Locomotives in Russia, Compound, Paper read by T. Urquhart before the Institution of Mechanical Engineers, 169*
Loop, Burnham's Steam, 601*
Lubricant Tester, Boult's Cylinder, 149*
Lubricator for Dynamine, 224*
"Lukin," Lathe The, 193*
Lyon's Improvements in Slide Valves, 272*

Machinery from Rating, Exemption of, 206, 543
Magnetic Phenomena, 210
Manchester Association of Engineers (see Engineers, Manchester Association of)
Manchester Ship Canal during 1889, Progress of the, 32
Marine Engineers, Institute of (see Engineers, Institute of Marine)
Mannesmann Process for Making Seamless Tubes, 569
Manwell's Ready Life Saver, 581*
Mather & Platt's Alternating Current Dynamo, 64*
Mauricewood Disaster, Report on the, 302
Mechanical Engineers, Institution of (see Engineers, Institution of Mechanical)
Meldrum's Breeze Furnace, 580*
Merchant Service, Efficiency in the, 278
Meteorological Society, Royal, 182
Mexico, British Investments in, 278
Midgley's Boiler Flues, 128*
Miley's Tapping Tool, 290*
Military and Naval Departments, Report on the, 422
Milk Factory, Swiss Condensed, 547*
Mill Disaster, The Templeton, 182
Miners and Papermakers, Arbitration Among Scotch, 86
Mines, Electric Locomotive for, 209*
Mining Engineers, Federated Institution of, 139, 423
Mining in 1889, 41, 517
Mixer, Welch's Improved, 329*
Morality, Commercial, 158
Morgan & Co. *v.* Windover & Co., 327
Morison's Evaporator and Feed Water Heater, 472*
Moseley's Packing for Engines, 379*
"Mosquito," H.M. Gunboat, 464, 540*
Mullineux's Cartridge, 8*
Mumford & Moodie's Separator, 385*
Musgrave's Triple-Expansion Mill Engine, 123*

Nasmyth, The Late James, 446
Naval Architects, Institution of, 303, 313, 325, 338*, 361*, 385
Naval and Military Departments, Report on the, 422
Navigation, International Congress on Inland, 566
Navy, Appointment of Assistant Engineers in the, 398
Navy, Engines and Engineers of the, 301
Navy Estimates, The, 277
Navy Proposals, American, 86
Navy, Speed of Vessels in Our, 38
New York, Electric Lighting at, 19
New York Electrical Subways, Practical Working of the, 259, 282, 306, 330
New York, The Hudson Tunnel at, 508*
"Newark," United States Cruiser, 440*
Nitrate, Trade in, 212

Oakey *v.* Flatau, 591
Oerlikon Screwing Machine, 5*
Oil Measuring Pump, Dutton's, 497*
Ore Crushing Mill, The Fulton, 409*
Ore Crushing Mill, The Lamberton, 516*
Oxygen Dissolved in Water, Estimation of, 115
Oxygen, Mechanical Appliances Employed in the Manufacture and Storage of, Paper read by K. S. Murray before the Institution of Mechanical Engineers, 219*

Packing Rings, Downie's, 73*
Packing for Engines, Moseley's, 379*
Paper Trade, Hours of Labour and Wages in the, 62
Papermakers and Miners, Arbitration among Scotch, 86
Paris, Electric Supply Stations at, 355
Paris Exhibition, The Late, 416
Parkinson's Drilling Machine, 416*
Patent Statistics, 1864–1889, 74
Patents, Notes on, 62, 121, 147, 219
Patents, The Lane Fox, 473
Petroleum Engine, Butler's Domestic, 464*
Petroleum Engine, Daimler's, 553*
Physical Society, 92, 160, 211, 283, 304, 401, 450, 524, 595
Pickles' Planing, Thicknessing, and Glass Papering Machine, 608*
Pictures by Telegraph, Sending, 195*
Planing Machine, Plate, 132*
Planing, Thicknessing, and Glass Papering Machine, 608*
Pollok's Gold Extracting Process, 161*
Polytechnic Institute for South West London, 300
Post, Imperial Penny, 566
Postal Jubilee, 485
"Princess Victoria," Royal Mail Paddle Steamer, 449
"Prins Willem II.," The s.s., 409*, 433*
Printing Machine, Godfrey Printing Machine Company's, 337*
Printing Machines, Apparatus for Feeding, 378*
Professions, Three Modern, 457
Profit Sharing, 14
Protractor, Draughtsman's, 224*
Pump and Gas Engine, 485*
Pumping Engine, Knight's Direct Acting Hydraulic, 392*
Pump, Dutton's Oil Measuring, 497*
Pumping Machinery for the Japanese Government, 268*
Punching Machine, Bennie's Large Lever, 84*

Railway Accident at Carlisle, 470, 494
Railway and Canal Traffic Act, 158, 206, 398
Railway, Edinburgh Underground, 206, 615
Railway, Girard's Hydraulic, 352*
Railway Rates Inquiry, 38, 470
Railway Sleeper, Improved, 41*
Railway Trucks for Mineral Traffic, Large, 85
Railways and British Traders, British, 494
Railways, Chinese, 109
Railways, Webb & Thompson's Staff Apparatus for Single Line, 104*
Ransome, Sims, and Jefferies' Valve Gear, 77*
Rating of Machinery, The, 206, 543
Rates Inquiry, Railway, 38, 470
Reducing Valve, Reid's, 196*
Retorts, Yeadon & Adgie's Gas, 426*
Richardson's Compound High Speed Engine, 425*
Riveting Plant, 200-ton Hydraulic, 316*
Rochester, Agricultural Show at, 568

"City of Paris," Accident to the—George Quick, 399; Marine Engineer, 423
Coal in Kent—F.G.S., 207
Coal Supply, Duration of Our—Black Diamond, 135

Deptford Electric Light Station—F. S., 375

Electric Lighting Plant, A ½-Kilowatt—Ed. C. de Segundo, 591
Engineers, Institution of Mechanical—Thos. Hunt, 471; Marine Engineer, 471

Fog and Atmospheric Electricity—W. H. Daniels, 207
Forth and Clyde Canal, The—Eon Strathaar, 375
Forth Bridge, Steel at the—F. J. R. Carulla, 256
France and England, Communication between—T. C., 40, 136; Eug. Obach, 111; Thomas Davis, 591

Gas, Melting Steel with Water—Gas, 327
Gas Stokers' Disputes—T. M., 15, 39; Chas. W. Rausch.

Howe's Metallurgy of Steel—Metallurgist, 615

Iron and Steel Institute, The—Metallurgist, 495
Italy, Protection in—Tariff, 592

Japan, Production of Coal in—Mitsui & Co., 399
Journals, Friction and Lubrication of Cylindrical—John Goodman, 399

Labour Disputes, Adjustment of—Sir J. Lubbock and K. B. Murray, 159
Lane Fox Patents—C. A. Stephenson, 543 567
Letter Express, A—F. G. Heath, 543
Locomotive Practice—Loco, 256

Machinery, Rating of—F. B., 303
Manchester Ship Canal—Inquirer, 183
Marking of Goods—A. Rose, 87
Mining Engineering, Electricity in—M. E., 135
Mining Machinery for South Africa—S. A., 231
Murdoch, William—A. Murdoch, 111; C. J. W., 183

Naval Architects, Institution of—Sigma, 447

Paris Exhibition, The British Committee of the late—H. Trueman Wood, 303
Piece Work—J. D. W., 495, 567; A. P. Trotter, 519; A Former Mechanic, 543
Pig Iron Warrants—A User of Iron, 519
Platinum for Electrical Purposes—W. M., 279
Plumbago—Galicia, 616

Rack-rented Tradesmen and their Customers—J. Haysman, 231
Railway System, Suggestions for a New Scottish Main—Eon Strathaar, 399, 471; M., 448
Railway Trucks for Mineral Traffic, Large—M. R. Jefferds, 135

Silicon in Iron and Steel—Metallurgist, 183
Silk Exhibition, The—Thos. Wardle, 279
Smit's Combined Engine and Dynamo—An Engineer, 376; L. Chandler, 399
Steatite as a Pigment for Anti-Corrosive Paints—C. Fairholme, 424
Strikes? Can an Improved Education Prevent—J. Stafford Ransome, 544
Sun and Planet Motion—A. Murdoch, 88

Telegraph, Paying Cheques by—H. Rickinson, 375
Then and Now—A Scot in London, 255
Torpedo Boats, English *v.* German—F. W. Crohn, 15
Tramcars, Compressed Air—Car, 327, 375, 471, 544; A. W., 327; Hughes & Lancaster, 351, 424, 519; F. Baines, 398
Transformers, Safety Apparatus for—B. Drake, 40

Welding, Thomson's Electric—N. D. O., 327
Wolseley Sheep Shearing Machine, The—H. E. Macleod, 592

Patents.—Subject Matter.

(*All Abstracts marked thus * are Illustrated.*)

Accumulator Plates, 287
Accumulators, Electric Switch for, 456
Acid Resisting Lining for Barrels, 240
Air Compressors, 214*, 431*
Air Propellers, 71, 119*, 142, 286, 335, 384
Alcohol, Rectifying, 24
Aluminium, 240, 504
Aluminium Alloys, 480
Ammonium Calcium Phosphate, 240
Anchors, 214
Annealing Furnaces, 384
Annunciator, Electric, 312
Anti-Friction Rings, 264
Arc Lamps, Electric, 168*, 408*, 456, 528*
Armour Plating, 47, 382
Axles, Manufacture of, 190*

Bark Mills, 431*
Barrels to Resist Acids, Lining, 240
Bars, Cutting Metal, 311
Batteries, Primary, 360, 456
Battery Plates, Secondary, 287
Bearings, 190, 287, 454, 480
Bearings, Thrust, 215
Bell, Electric, 144
Bells for Signalling, 95, 456
Belts, Driving, 72
Bending Plates, 118
Bends, Flexible, 359
Bleaching Fabrics, 72
Blowers, 71, 119*, 142, 286, 335, 384
Boats, Ferry, 286
Boats, Paddle, 119
Bobbins, 190
Boiler Tube Stoppers, 215, 335
Boilers, Removing Scale from, 71
Boilers, Steam, 72, 96*, 142, 143, 239, 311, 334, 382, 430, 624*
Bolts and Nuts, Shaping, 287*
Boot Machinery, 407*, 455
Bottle Washing Machine, 432*
Braces, Ratchet, 312
Brake for Hoisting Apparatus, 46, 71
Brakes, Railway, 406, 527*, 576
Branding Machines, 551*
Brewing, Preparing Cereals for, 527*
Brick Making Machines, 71*, 430
Bronze, Silicon, 192
Buffers, 215, 407

Cables for Electric Conductors, 120
Calcining Furnaces, 263*
Calcium Phosphate, Ammonium, 240
Calendering Apparatus, 359
Canal Boats, Propelling, 552
Capstans, 598*
Carbonic Acid, Collecting, 384
Carding Engines, 46*, 166, 358*, 478
Carding Flats, 287
Carding Flats, Grinding, 334
Carding the Backs of Cords, 191
Casting Metals, 311*, 527
Casting under Pressure, 382*
Cellulose, Sulphite, 72
Centrifugal Dye Extractors, 48, 215*
Centrifugal Separators, 216, 478*, 574
Chain and Rope Gearing, 287
Chain Gearing, 622
Chains, Manufacture of, 311*
Chlorine, 120, 288*
Circular Form, Reducing Bodies to a, 479*
Clipping Animals, Apparatus for, 310*
Cloth, Apparatus for Treating, 263*
Cloth, Cooling, 120
Clutch, 359
Coal Screening and Breaking Apparatus, 239
Coal Waggons, Loading, 526*
Cock, Gas, 576
Coir Yarn Mat Machinery, 455*
Coke Ovens, 384
Colliery Tub Wheels, 382
Colouring Matters, 24, 144, 168, 192, 312, 384, 456, 528
Combing Machines, 22*, 94*, 527
Compressors, Air, 214*, 431*
Condensers, 168
Conductors, Cables for Electric, 120
Conductors, Conduits for Electric, 240, 600
Conductors, Supporting Electric, 456
Conductors, Testing Electric, 192
Conduits for Electric Conductors, 240, 600
Conveyer, Screw, 167
Conveyers, Grain, 71
Copper, 288
Copper and its Alloys, 240
Copper, Coating Iron with, 336
Cork Making Machines, 598*
Corliss Valves, 239
Corrosion, Material for Preventing, 336
Cotton, Drying, 239
Couplings, Railway, 334*, 407, 526
Cranes and Turntables, 262
Cranes, Hydraulic, 118*
Cranes, Safety Valve for Hydraulic, 46
Crank Pins, Adjustable, 382*
Crushing Mills, 144, 167, 190, 215*, 239, 286*
Cushioning Devices, 430
Cut-outs, Electric, 480*, 600*
Cutting Metal Bars, 311
Cutting Metals, 167
Cyanogen Compounds, 120

Damping Warps in Looms, 94, 310
Decorticating Ramie, 623*
Despatch Apparatus, Electromagnetic, 168*
Dies for Rolled Forgings, 263
Disinfecting Fluids, Diffusing, 552
Distillation, Fractional, 168
Distributor, Pneumatic, 214
Drain Openings, Covers for, 22
Draining Land, 120*
Drawing Metals, 336
Dredgers, 71*, 142, 238*
Drills, Rock, 71*, 166*, 214, 575, 622
Driving Belts, 72
Drying Apparatus, 455*
Dust Collector, 359
Dye Extractors, 48, 215*
Dyeing and Printing Fibres, 192
Dyeing Yarns, 360
Dynamometers, 431*
Dynamos, 48, 48*, 384*, 432*, 504*, 504, 600
Dynamos, Regulating, 360*

Eccentrics, Adjustable, 382*
Electric Arc Lamps, 168*, 408*, 456, 528*
Electric Alarm for Pressure Gauges, 576
Electric Annunciator, 312
Electric Bell, 144
Electric Cables, 120
Electric Circuits, Interrupting, 552*
Electric Conductors, 192
Electric Conductors, Conduits for, 240, 600
Electric Conductors, Supporting, 456
Electric Control for Steam Steering Gear, 240*
Electric Cut-outs, 480*, 600*
Electric Firing Apparatus, 432
Electric Firing Fuses, 360
Electric Furnaces, 528*
Electric Incandescent Lamps, 120, 144, 312, 360, 504, 624
Electric Instruments, Bases for, 191
Electric Lamp Holders, 72
Electric Meters, 168, 191, 312*, 360*
Electric Railways, 72, 191, 336, 552

Digitized by Google

Electric Regulation, 96, 144, 264*, 360*, 408* 624*
Electric Signalling Lamps, 264*
Electric Switch for Accumulators, 456
Electric Switches, 120*, 168, 168*, 383, 504
Electric Transformers, 383
Electric Welding, 288*
Electricity on Railway Trains, Generators of, 264
Electrolysis, 408*
Electromagnetic Despatch Apparatus, 168*
Electromechanical Movements, 480
Electromotors, 192*, 432*, 504*, 528
Electromotors, Regulating, 408*
Elevators (see Lifts and Hoists)
Elevators for Grain, 575*
Engine for Terrestrial and Aërial Propulsion, 406*
Engines, Gas, 23*, 46, 48*, 119, 119*, 143*, 166, 167, 191*, 287, 311*, 336, 358*, 359, 407*, 430*, 527*, 550*, 575

Engines, Petroleum, 144*, 430*, 550, 574, 575
Engines, Rotary, 71, 216*, 262*, 335*, 383*, 406*, 527*, 550*
Engines, Steam, 24, 167, 214*, 215, 238*, 263, 287*, 311*, 334*, 336*, 574*, 576, 624
Engines, Steam and Air, 382*, 407*
Ensilage, 384
Ethers, Para-amidophenol, 144
Evaporating Apparatus, 22*, 96*, 600
Excavators, 71*, 142, 238*
Explosives, 192, 240

Fans, 71, 119*, 142, 286, 335
Fans, Electrically Driven, 384
Feed Water Heaters, 576
Feed Water, Purifying, 239*, 454*, 503
Feed Water, Regulating, 455
Ferry Boats, 286
Filaments for Electric Lamps, 336
Filter Presses, 70*, 383, 384, 504
Fire Damp, Indicating Presence of, 312
Fire Escapes, 72, 216*
Fire Extinguishing Sprinklers, 142*
Firing Apparatus, Electric, 432
Flanges, Pipe, 335
Flanging and Shaping Metal Plates, 239
Flats, Carding, 287
Flats, Grinding Carding, 334
Fly Wheels, 263
Fog Signals, 480, 526
Forgings, Dies for Rolled, 263
Friction Gearing, 622
Fuel, Machines for Making Block, 359*, 408
Furnaces, Annealing, 384
Furnaces, Boiler, 23, 168*, 262, 336, 478, 502, 502*, 503, 551, 574, 623*
Furnaces, Calcining, 263*
Furnaces, Electric, 528*
Furnaces, Gaseous Fuel, 70*, 120
Furnaces, Iron and Steel, 120
Furnaces, Liquid Fuel, 118*
Furnaces, Locomotive, 287
Fuses, Electric Firing, 360

Galvanometers, 480*
Gangways, Ships', 431
Gas Cock, 576
Gas Engines (see Engines, Gas)
Gas Lamps, Regenerative, 24*
Gas, Manufacture of, 24*, 47, 455, 575
Gas Producers for Marine Boilers, 120
Gas Retorts, 575
Gas, Water, 264
Gases, Altering the Proportion of Mixed, 431*
Glass Lined Tubes, 479
Glass, Ribbed, 550
Glass Tanks for Acids, 552
Gold and Silver, Extraction of, 24, 360*, 432, 456*
Governors, 118*, 430
Grain Conveyers, 71
Grain Elevators, 575*
Grain Separators, 71
Grinding Rollers, 24
Guns on Railways, Working, 622
Guns, Turret Mounting for, 551*

Hackling Machines, 263*
Hammers, Steam, 166, 623*
Hand-Driving Mechanism and Treadle Combined, 478
Heating Apparatus, 430, 479, 504
Heeling Machines, 191
Hoisting Apparatus, Brake for, 46, 71
Hoists, 47, 47*, 454
Hydraulic Transmission of Power, 336

Incandescent Electric Lamps, 120, 144, 312, 360, 504, 624
Indiarubber, Substitute for, 192
Injectors for Raising Acid Liquors, &c., 70*
Insulators, 287
Interlocking Apparatus for Railways, 142*
Iron and Steel Furnaces, 120
Iron Bars, Piling Wrought, 166
Iron Carrier and Breaker, Pig, 336
Iron, Extraction of, 288
Iron, Homogeneous, 288
Iron Wires, Coating, 336
Iron with Copper, Coating, 336
Ivory, Substitute for, 336

Jacks, Lifting, 143*, 503
Jacquard Cards, Reading and Punching, 118
Journal Boxes, 119

Knitting Machines, 191*

Lace, Stretching, 383
Lamp Holders, Electric, 72
Lamps, Electric Arc, 168*, 408*, 456, 528*
Lamps, Electric Incandescent, 120, 144, 312, 360, 504, 624
Lamps, Electric Signalling, 264*
Lamps for Railway Carriages, 72
Lamps, Miners', 528*
Lamps, Regenorative Gas, 24*
Lathes, 190*, 216, 239, 263
Lathes for Stone, 46
Lead, White, 24, 312, 384
Leather Rolling Machine, 96*
Leather Skiving Machines, 478*
Lifts and Hoists, 47, 454
Lifts, Hydraulic, 23*, 71, 623*
Lightning Arresters, 264*
Liquids, Separating Solids from, 167*
Lock Nut, 238, 262
Locomotive Furnaces, 287
Locomotives, 358
Locomotives, Compound, 22*
Locomotives for Towing Purposes, 503*
Log, Ship's, 431*
Looms, 22, 48, 94, 95*, 119, 168, 263, 286, 310, 334*, 335*, 382, 431, 502, 526*, 551*, 599
Lubricators, 118, 142*, 190*, 407, 431, 478, 599

Magnesium Chloride and Oxychlorides, 504
Magneto-electric Machines, 216
Malt, Cleaning, 574*
Malt, Making and Drying, 576
Mat Machinery, Coir Yarn, 455*
Mercaptan, Ethyl, 384
Metallic Coverings, Flexible, 239*
Metals, Cutting, 167
Meters, Electric, 168, 191, 312*, 360*
Meters, Liquid, 551*
Milk, Purifying and Preserving, 384
Milling Cutters, 216
Milling Machine, 430
Milling Tools, Apparatus for Cutting, 94*
Miners' Safety Lamps, 528*
Motive Power, Obtaining, 95*
Mules, 263, 383*

Nut Locks, 238, 262
Nuts and Bolts, Shaping, 287*

Oil Presses, 550*
Oils, Distilling, 552*
Ores, Treating, 192, 504*
Ores, Washing, 144

Packing for Piston Rods, 622
Paddle Wheel Boats, 119.
Petroleum Engines (see Engines, Petroleum)
Petroleum Tanks, 526
Phonographs, 312
Phosphate, Ammonium Calcium, 240
Phosphorus, 576
Pickle, Waste Sulphuric Acid, 264
Pig Iron Carrier and Breaker, 336
Piling Wrought Iron Puddle Bars, 166
Pipe Flanges, 335
Piston Rings, 479*
Piston Rods, Packing for, 622
Pistons, 118, 574*
Plates, Armour, 47, 382
Plates, Bending, 118
Plates, Flanging and Shaping Metal, 239
Ploughs, Snow, 600*
Pneumatic Distributor, 214
Posts, Fixing, 600
Potassium and Sodium Hydrates, 264
Power, Hydraulic Transmission of, 336
Power, Obtaining Motive, 95*
Presses, 23*, 502*, 503*
Presses for Extracting Oil, 550*
Presses for Plastic Substances, 550
Presses for Pulp, 600
Presses, Hydraulic, 432*
Pressure Gauges, 575, 576
Printing and Dyeing Fibres, 192
Printing Machines, 70
Printing Telegraphs, 120
Propeller Shafts, Screw, 238
Propellers, Appliance for Removing Screw, 94
Propellers, Governing Screw, 526*
Propellers, Screw, 94, 168, 215, 406, 456
Propelling Ships, 311, 359*, 574, 622
Pulley Blocks, 143
Pulleys, 622
Pulleys, Split, 358
Pulleys upon Shafts, Securing, 310
Pulverisers, 144, 167, 190, 215*, 239, 286*
Pump, Air, 406
Pumping Engines, 214*, 215, 262, 359*, 479, 552, 575, 576
Pumps, 335, 454, 622
Pumps and Fans, Centrifugal, 71, 119*, 142
Punkahs, Apparatus for Working, 47

Railway Brakes, 406, 527*, 576
Railway Couplings, 334*, 407, 526
Railway Signalling, 287, 288, 335
Railway Switches, 239
Railway Wheels, 599
Railway Trains, Generation of Electricity on, 264
Railways, Electric, 72, 191, 336, 552
Railways for Ships, 95
Railways, Indicating Names of Stations on, 264
Railways, Interlocking Apparatus for, 142*
Railways, Permanent Way of, 48, 95, 166, 239, 288
Railways, Working Guns on, 622
Ramie Machinery, 623*
Ratchet Braces, 312
Reaping Machines, 383*
Reciprocating into Rotary Motion, Converting, 239
Reciprocating Rotary Motion, 142
Refrigerating Chambers, 47
Refrigerating Machines, 215, 430
Regulation, Electric, 96, 144, 264*, 360*, 408*, 624*
Retorts, Gas, 575
Rings, Anti-friction, 264
Rock Drills, 71*, 166*, 214, 575, 622
Rolled Forgings, Dies for, 263
Rollers, Coverings for, 142
Rollers, Grinding, 24
Rolling Mills, 94*, 119, 311
Rolling Seamless Tubes, 166*
Rope and Chain Gearing, 287
Rope Driving Gear, Reversible, 119
Ropes, Hemp, 480
Ropes, Wire, 118
Rotary Engines (see Engines, Rotary)
Rotary Motion, Converting Reciprocating into, 239
Rotary Motion, Reciprocating, 142
Rudders, Duplex, 359

Sand Blast Machinery, 95*, 190, 238*
Sawing Machinery, 48, 527
Sawing Stone, 575*
Saws, Veneer, 94
Scale from Boilers, Removing, 71
Screening and Breaking Coal, 239
Screw Conveyer, 167
Screw Cutting Lathes, 239
Screw Threads, Forged, 574
Scutching Machines, 286, 310*, 479*
Separators, Centrifugal, 216, 478*, 574
Separators for Grain, 71
Shaping Machines, 239, 383
Shearing Animals, Apparatus for, 310*
Ship Railways, 95
Ships, 214, 336, 479
Ships' Bottoms, Protecting, 528
Ships' Gangways, 431
Ships, Propelling, 311, 359*, 574, 622
Ships, Raising Sunken, 143
Ships, Signalling Between, 430
Signal Bells, 95, 456
Signalling Between Ships, 430
Signalling Lamps, Electric, 264*
Signalling, Railway, 287, 288, 335
Signalling upon Steamships, 288
Signals, Fog, 480, 526
Silicon Bronze, 192
Silk, Artificial, 120
Silk Winding and Drawing Machines, 239
Silver and Gold, Extraction of, 360*, 456*
Slag, Utilisation of, 576
Sleepers and Chairs, Railway, 95
Smoke Consumers, 598*
Snow from Streets, Removing, 216
Snow Ploughs, 600*
Sodium and Potassium Hydrates, 264
Solids from Liquids, Separating, 167*
Sounding Apparatus, 335*
Speaking Tubes, 72, 432
Spindle Bearings, 120
Spinning Machines, 118, 262*, 286, 407*, 454* 599*
Spring Making Machines, 48*
Springs, Laminated, 407
Sprinklers, Fire Extinguishing, 142*
Stamping Machines, 23*
Starting Vehicles, 214*
Steam, Drying, 624
Steam Engines (see Engines, Steam)
Steam Traps, 95*, 262, 502
Steamships, 336
Steamships, Reversible, 574
Steamships, Signalling upon, 288
Steel, 384, 431, 455
Steel and Iron Furnaces, 120
Steel Tubes, Hardening, 240
Steering Gear, 359
Steering Gear, Electrically Controlled Steam, 240*
Steering Gear, Steam, 47, 311*, 599
Stokers, Mechanical, 238, 286, 623*
Stone Breaking Machinery, 22*
Stone, Lathes for, 46
Stone Sawing Machines, 575*
Stone, Tools for Working, 119*
Stoppers, Boiler Tube, 215, 335
Sulphuric Acid Pickle, Waste, 264
Sunken Ships, Raising, 143
Switch for Accumulators, Electric, 456
Switches, Electric, 120*, 168, 168*, 383 504
Switches, Railway, 239

Tanks for Acids, Glass, 552
Tapping Tool, 310*
Telegraphs, Printing, 120
Telephone Mouth Pieces, 216
Telephone Transmitters, 287
Telephones, 96*
Telephones, Water, 408*
Textile Fabrics, Finishing, 598*
Theatre Doors, Controlling, 600
Thrashing Machines, 70
Thrust Bearings, 215
Tides, Obtaining Motive Power from, 24
Tinplate Mills, Grinding the Rolls of, 119
Tinplate Scrap, Treatment of, 576
Tinplates, 216, 240*, 526*, 528
Tramcars, Restarting, 502*
Tramway Engines, 311*
Tramway Points, 48, 286
Transformers, Electric, 383
Transmission of Power, Hydraulic, 336
Traps, Steam, 95*, 262, 502
Treadle and Hand Driving Mechanism, 478
Tube Stoppers, Boiler, 215, 335
Tubes, Flexible Metallic, 478
Tubes, Forming and Polishing, 72*
Tubes, Glass Lined, 479
Tubes, Hardening Steel, 240
Tubes, Manufacture of Metallic, 455*
Tubes, Rolling Seamless, 166*
Tubes, Speaking, 72, 432
Turbines, 167*
Turbines, Percussion, 216
Turbines, Steam, 358
Turn-Tables and Cranes, 262
Tuyeres, 167*, 407, 478
Twisting Machine, Wire, 143*
Twisting Yarn, 454*

Valve, Air, 240
Valve Gear, 191, 286*, 503*, 527
Valve, Mixing and Suction, 72
Valves, Corliss, 239
Valves, Gate, 95
Valves, Slide, 22, 143, 479, 502
Vehicles, Starting, 214*
Velocipede, Water, 551
Veneer Saws, 94
Vices, 214

Waggons, Loading Coal, 526*
Warp Balling Machine, 599*
Warping Machines, Sectional, 382*
Washing Bottles, Machine for, 432*
Water, Softening and Clarifying, 96
Welding, Electric, 288*
Wheels, Colliery Tub, 382
Wheels, Fly, 263
Wheels, Gear, 214
Wheels, Railway, 599
Winding Yarn, 406
Wire, Coating Iron, 336
Wire Ropes, 118
Wire Straightening and Cutting Machine, 551*
Wire Twisting Machine, 143*
Wire with Cotton, Covering, 47*
Wringing Machines, 216

Yarn, Twisting, 454*
Yarn, Winding, 406
Yarns, Dyeing, 360

Names of Patentees.

Abel, C. D.—Colouring Matters (Actiengesellschaft für Anilinfabrikation), 24, 312; Propeller Shafts (Gas Motoren Fabrik Deutz), 238
Ackermann, A.—Dynamometers, 431*
Adams, M. J.—Gas Engines, 119
Adler, C., and another—Signalling Trains, 288
Aiken, H.—Manufacture of Railway Axles, 190*; Casting Ingots, 311*
Allan, J., and others—White Lead, 312
Alley, S.—Treating Metallic Ores, 504*
Amoroso, F. F. (see Haddan, H. J.)
Anchill, F. W., and another—Grain Elevators, 575*
Andersen, F. V.—Galvanometers, 480*
Anderson, R. W.—Lubricators, 142*
Andrews, T.—Screws for Furnace Feeding, 238
Anilinfabrikation, Actiengesellschaft für (see Abel, C. D.)
Appleberg, J. T.—Purifying and Preserving Milk, 384
Archbutt, L., and another—Softening and Clarifying Water, 96
Archer, T., and others—Signalling upon Steamships, 288
Armitage, A., and another—Apparatus for Cooling Cloth, 120
Armstrong, J.—Glass Tanks for Batteries, 552
Ashworth, J., and another—Looms, 599
Atherton, J.—Wire Twisting Machine, 143*
Atkins, E. E., and another—Oil Lamps for Railway Carriages, &c., 72
Atkinson, L. B.—Electric Motors, 528
Atkinson, T., and another—Damping Warps in Looms, 94

Babo, A.—Chain Gearing, 622
Baker, J. S.—Paddle Wheel Boats, 119
Bamberg, G.—Alloys of Aluminium, 480; Aluminium, 504
Banfield, R. C. A.—Refrigerating Chambers, 47
Bang, I., and another—Coating Plates with Tin, 528; Treatment of Tinplate Scrap, 576
Bangs, E. D.—Lubricators, 118
Banner, S.—Lubricating Apparatus, 190*
Bannister, M. C.—Refrigerating Machines, 215*
Barber-Starkey, W. J. S.—Electric Cut-outs, 480*
Barker, F.W.—Driving Belts (Nichols F.W., & Ingersoll, J. E.), 72
Barlow, J.—Chucks for Lathes, 263
Barn, J. N. (see Thompson, W. P.)
Barnett, G.—Recovering Sunken Vessels, 143
Barraclough, T. C.—Covering Wire with Cotton, &c., 47*
Barthel, A. E.—Production of Homogeneous Iron, 288
Bass, T.—Ratchet Braces, 312
Bastow, S.—Sawing Machinery, 527
Baumgartner, R. A.—Cleaning Malt, 574*
Bayer, F., & Co. (see Willcox, B.)
Bear, T. M., and another—Shaping Machines, 383
Beaumont, W.—Centrifugal Pumps, 142
Becher, J. M. (see Justice, P. M.)
Beckfield, J. C., and another (see Lake, H. H.)
Beckwith, J. H., and another—Slide Valve Gear, 502
Bell, T.—Lining Barrels to Resist Acids, 240
Bénier, L.—Steam Engines, 334*
Benson, W. A. S.—Supporting Electric Conductors, 456
Berkefeld, H. W.—Cleansing Filters, 383
Berry, B., and another—Picking-Stick Tappets of Looms, 382
Berry, F. H.—Electric Bell, 144
Bilharz, O. (see Dymond, G. C.)
Bird, E. E.—Wire Ropes, 118
Birkbeck, H.—Grinding Mills (Jones, J. & A. J.), 144
Blair, W.—Propelling Vessels, 311
Blass, E., and another—Water Gas, 264; Altering the Proportion of Mixed Gases, 431*
Bleasdale, H.—Rotary Engines, 527*
Blendorf, A. S. von, and another—Signalling Trains, 280
Bohnen, L., and another—Rotary Engines, 383*
Bond, B. R.—Spindle Bearings, 120
Bontemps, L., and another (see Boult, A. J.)
Bontet, P., and another (see Boult, A. J.)
Bookwalter, J. W. (see Boult, A. J.)

Booth, J.—Machines for Knitted Pile Fabrics, 191*
Boult, A. J.—Gas Motors (Capitaine, E.), 167; Compressed Air Generators (Bontemps, L., & Bontet, P.), 431*; Converters for Metal (Bookwalter, J. W.), 455
Boulton, J. W.—Steam Generators, 382
Bour, E. F.—Water Velocipede, 551
Bower, J.—Appliance for Removing Screw Propellers, 94
Bowron, G.—Magneto-Electric Machines, 216
Boyd, J.—Spinning and other Machinery, 262*
Boys, C. V.—Insulators, 287
Bradford, T.—Water-Heating Apparatus, 430
Brassington, J. T., and another—Rolling Mills, 94*
Brearley, A. & R.—Apparatus for Treating Cloth, 263*
Briggs, D. B., and another—Picking-Stick Tappets of Looms, 382
Brindle, J., and others—Carding the Backs of Cords, &c., 191
Brindley, J.—Steam Vacuum Pumps, 552
Brocklehurst, H., and another—Indicating Stations, &c., 288
Bronner, P.—Manufacture of White Lead, 384
Brooke, M. E., and another—Fog Signals, 480
Brotherhood, P.—Slide Valves, 479
Brown, A.—Steam Ferry Boats, 286
Brown, A. G.—Steam Dryer, 624
Brown, C. H., and another (see Sloan, R. A.)
Brown, E. V.—Bark Mills, 431*
Brown, J. W., and another—Steam Engine Governors, 430
Brüngger, H., and another—Sulphite Cellulose, 72
Brutton, R. H., and another—Starting Gas Engines, 287
Bryden, W., and another—Self-acting Mules, 263
Budd, G. W., and another—Lathes, 190*
Bull, J. C.—Petroleum Engines, 574
Bullough, J.—Carding Engines, 358*
Burges, G., Jun.—Bottle Washing Machinery, 432*
Burleigh, W. F.—Interlocking Apparatus for Railways, 142*
Burnell, R. A.—Primary Batteries, 456
Burrow, J., and another—Tramway Points, 286
Butler, W. F.—Colliery Tub Wheels, 382

Caldwell, E. P. (see Thompson, W. P.)
Callard, P. & V. (see Thompson, W. P.)
Cannon, W. G.—Hot Water Coils, 479
Cant, B. C. C.—Electric Indicators, 312
Capeyron, C.—Steam Engines, 287*

Industries.

INDUSTRIES AND COMMERCE DURING 1889.

IT has not hitherto been our agreeable duty to undertake the presentation of so favourable a report on the circumstances of national industry and commerce as we are able to offer on the trade of the past year. There have, as will always be the case, been certain aspects of business that have been matter for regret. There have been more strikes than is usual, and some of them have been attended with a good deal of loss and suffering. There has also been more speculation, especially in the iron and cotton trades, than is compatible with sound and solid business, and the apprehensions of legitimate manufacturers and dealers have thereby been justly excited. But our trade, taken as a whole, has developed a healthy activity, which has culminated in a higher range of prices nearly all round, and the year closes with better prospects for our principal industries, and notably for the iron, steel, cotton, engineering, and shipbuilding trades—which are really the backbone of our industrial fabric—than they have known for years.

In the figures which are used for the purpose of illustrating and setting forth the course of our trade in 1889, we shall drop the last three figures, which are of little use for such a purpose when dealing with millions, and both complicate details and fatigue the eye. When we speak of 1889, we refer, of course, to the first eleven months of that year only, as the complete returns for the twelve months will not be available for some little time; and when we speak of comparing 1889 with previous years we shall deal with the corresponding periods, or first eleven months only.

AGRICULTURE.

The Returns issued by the Agricultural Department, showing the condition of the harvest of 1888, were by no means so satisfactory as might have been desired. They showed a decrease of serious amount in the production of wheat and potatoes, although there was a substantial increase in the production of oats, barley, beans and peas, turnips and hay. The harvest on the whole was, however, better than that of the previous year, and this, no doubt, has had its due amount of weight in reference to the range of prices and the extent of our imports of agricultural produce during the period that has since intervened.

The general current of prices has not flowed in the same direction, at any rate not to anything like the same extent, as that of other staple productions. The prices of wheat, flour, mutton, potatoes, and prime beef were actually lower at the end than at the beginning of 1889. Barley and oats, on the contrary, notwithstanding the fairly good crops of 1888, have taken a higher range. The current rates do not, on the whole, differ much from those quoted in 1887 and 1888, when the general circumstances of trade and commerce were far from being as favourable as they now are.

One of the most striking, and at the same time satisfactory, features of the import trade of the current year has been the enormous extent to which we have increased our consumption of food and drink. We have spent in our imports of these about 15 millions more than in 1888, and if we add the increase in our imports of tobacco, the amount of difference is brought up to about 16¼ millions. This, of course, means that there has been a great increase of purchasing power on the part of the masses—an increase which applies equally to almost all descriptions of food and drink, whether dutiable or not. Some descriptions of both have taken a higher range of prices than formerly, but the difference in this respect, taken over the whole, has not been very material. The increase of population, amounting to some 400,000 per annum on an average, would of course naturally lead to an increased consumption of imported breadstuffs, but the increase in 1889 has been far greater than would be likely to accrue from that source. The following table shows the quantities imported, and the average prices, deduced from the declared values, as set out in the Board of Trade returns:—

Imports of Corn and other Food Products into the United Kingdom in 1889 *compared with* 1888 (1 = 1,000).

	Quantities.		Values.		Average Value per cwt.	
Cereals, &c.:	1888. cwt.	1889. cwt.	1888. £	1889. £	1888. s.	1889. s.
Wheat	50,901	53,624	19,770	20,629	7·7	7·6
Flour	15,727	13,143	8,787	7,652	11·1	11·6
Barley	18,235	15,955	5,113	4,533	5·6	5·6
Oats	17,169	14,691	4,169	4,063	4·8	5·5
Indian corn	23,687	34,113	6,430	8,089	5·4	4·7
Oats	2,200	1,518	634	494	5·7	6·5
Beans	2,807	3,301	854	1,037	6·0	6·2
Potatoes	2,275	1,846	779	732	6·8	7·9
Butcher's Meat, &c.:						
Bacon	2,563	3,147	5,713	6,623	44·5	42·0
Hams	677	897	1,785	2,301	52·7	51·3
Fresh beef	755	1,251	1,733	2,739	45·9	43·7
Fresh mutton	912	1,117	1,793	2,367	39·3	42·3
Dairy Produce:						
Butter	1,524	1,760	8,089	9,310	106·1	105·7
Cheese	1,786	1,776	4,214	4,155	47·1	46·7

The import values appear to confirm the quoted rates for home agricultural produce during the year, and show that prices generally continue to take an exceptionally low range. Of course, it need hardly be observed that, so long as this low range of prices continues, it can hardly be well with English agriculturists, who have to compete with the agriculturists of every other country in the world. The rent of land has generally been so far reduced that farmers are better equipped for this struggle than they were, but local burdens continue to be very heavy, and the action that has been taken by many of the County Councils, in the way of local improvements, will probably increase them. There is, however, reason to believe that the number of farms unoccupied is much less than it was, and that the agricultural interest—the tenants as well as the landlords—is having a "better time." Wages have hitherto been falling, and have therefore been in their favour, but it is extremely unlikely that this advantage will be continued to the farmer if the wages paid to miners, dock labourers, and other inferior forms of employment keep up to their present level.

COTTON AND OTHER TEXTILES.

Up to the middle of 1889 the condition of the cotton industry could hardly be said to be satisfactory. The exports of cotton, both in the form of yarns and in that of manufactured goods, were on an exceptionally large scale, but the margin between yarn and cloth was narrow, and in all but the best mills was unprofitable. Grey piece goods were especially backward in price. The order books of manufacturers were by no means well filled, and as there was no disposition on the part of manufacturers to bear the risk of stocking goods, having regard to the frequent changes that have been current in widths and lengths, the outlook did not appear to be very promising. A number of the largest mills manufacturing T cloths and domestics were only running four days per week. Spinners, however, were making fairly satisfactory progress on the whole, in spite of the speculative manipulation of "futures" in New York and Liverpool, which was counteracted by hand and mouth buying generally, and in many cases by short time at the mills.

During the latter half of the year the cotton mills of Lancashire have been doing a very satisfactory business. The mills generally have been in full operation, and the most of them are well supplied with orders. There has been a disposition in several districts to take advantage of the situation by increasing the resources of production, and in the southern towns of Lancashire the additions now being made to existing plant are calculated to be equal to some 750,000 spindles. Cotton has been somewhat easier during the later months of the year, while yarn has kept up its price, so that spinners are in a somewhat better position than they were. The only probable rock a-head appears to be that of wages or other labour questions. An agitation has been commenced in Lancashire with a view to securing some amendments in the Factory and Workshop Act of 1878, providing more especially that each worker shall have 350 cubic feet of space; that every carding engine, coupling, neck, or socket shall be encased; and that every loom shall be provided with an effective shuttle-guard. There are a number of minor provisions that are not likely to be required so far as the best factories are concerned; but the more onerous provisions are likely to be irksome, and some of them will no doubt be regarded as totally uncalled for.

There has been a remarkable increase in the imports of raw materials for the textile manufactures, amounting to not less than £10,806,000. This increase, however, is not transferred to the other side of the accounts in the form of exports, the value of which have only increased by £958,000. Hence a paradox, that can only be explained by supposing that stocks of raw materials for the textile trades have been increased, which has not to any extent been the case; that the prices realised have not kept pace with the prices paid, which is also doubtful, seeing that the principal textile manufactures have been doing very well; or that a much larger proportion than usual of the raw materials imported have been worked up for home consumption, which would, of course, indicate a larger purchasing power on the part of the community generally.

The quantities and values of the raw materials imported for the textile trades compare as under for 1888 and 1889 (1 = 1,000):—

	1888. Quantity.	1888. Value.	1889. Quantity.	1889. Value.	Average Value per Cwt. 1888.	Average Value per Cwt. 1889.
	Cwt.	£	Cwt.	£	£	£
Cotton	12,810	32,902	14,620	38,353	2·5	2·4
Flax	1,704	2,753	1,641	2,801	1·6	1·7
Hemp	1,662	2,519	1,766	3,048	1·5	1·7
Jute	5,600	3,421	6,680	4,710	0·6	0·7
Totals	21,776	41,595	24,707	48,912		

	1888. Quantity.	1888. Value.	1889. Quantity.	1889. Value.	Average Value per lb. 1888.	Average Value per lb. 1889.
	lbs.	£	lbs.	£	d.	d.
Wool	583,396	23,721	655,786	26,764	9·7	9·8
Alpaca, &c.	3,873	161	4,562	230	9·9	12·0
Goats' hair	19,321	814	19,436	922	10·1	11·3
Raw silk	2,832	1,735	2,932	2,066	147·0	169·4
Totals	609,422	26,431	682,716	29,982		

These figures do not include the large quantity of woollen rags which we imported in 1889 to the amount of 63,470,000lb., in order to work them up again into woollen fabrics, nor the considerable quantity of silk imported as knobs, waste, and thrown or dyed material.

So far as the sources of the imports of textiles are concerned, what chiefly interests us in reference to cotton is the increase of 885,000cwt. in our imports from British India, but this, large though it appears, still fails to make up the total to those of some former years. The supplies from Brazil have greatly fallen off in 1889, while those from the United States have increased to the extent of about 750,000cwt. The increased supplies

Digitized by Google

of wool have been mainly contributed by European countries, which have added some 39,000,000lb. to their record for 1888. British India has also sent us much larger supplies of raw silk, while Japanese silks have fallen off to the extent of over 200,000lb. China, however, continues to hold the field, and has increased the record for 1888 by some £300,000.

Coming, now, to the other side of the account, we find that the exports of textile fabrics in 1889 compared as under with the previous year as regards quantity and value (1 = 1,000):—

	1888. Quantity.		Value.
Cotton yarn and twist	lbs.	235,329	£10,698
„ piece goods	yds.	2,122,898	18,874

Alpaca, mohair, &c.	lbs.	12,192	1,067

The total value of our exports of yarn and textile fabrics in 1889 was £101,131,000, as compared with £100,173,000, the corresponding values of imports of raw materials having been £81,074,000 and £70,268,000.

The Board of Trade have this year introduced some changes in their tabulation of the returns of cotton imports, which are likely to be appreciated. They have for the first time, in tabulating the exports of cotton yarn, separately distinguished grey and bleached, and dyed yarn and twist. They have also for the first time separately distinguished printed piece goods, and dyed or coloured piece goods, from the total of all piece goods.

In the following table the average current quotations for textiles in the first week of December of each of the last three years are stated:—

	1887. Pence per lb.	1888. Pence per lb.	1889. Pence per lb.
Cotton, raw (middling upland)	5⅜	5½	5⅝
Yarn, 40 mule twist	8⅜	8¾	9
Wool, Southdown	11¼	11	12
„ N.S. Wales average	8	9½	11
	Per ton.	Per ton.	Per ton.
Flax, Petersburg	£28 0 0	£27 0 0	£23 0 0
Hemp, Manilla	36 10 0	42 10 0	52 0 0
Jute, good marks	14 0 0	17 0 0	16 0 0

IRON AND STEEL.

On examining the returns of the exports of iron and steel for 1889, it appears that there has only been the comparatively small increase overhead of 202,000 tons in the quantity, while there has been an increase of £2,299,000 in value. Pig iron, railroad iron, hoops and sheets, tinplates, and cast or wrought, show an increase, while there has been a decrease in the exports of bar and angle iron, wire, old iron, unworked steel, and steel manufactures. The total value of the exports of iron and steel in 1889 was £26,645,000, but it need hardly be observed that if the prices current in the last three months of the year had been current all round, the realised value would have been much greater than it really has been. There are always large quantities of iron and steel, as of most other commodities, being worked off at old prices, so that manufacturers are only able to take advantage of current rates as regards a part of their production only, and that part is often a small one. Of course, also, as regards the quantity exported during the first six months of the year, there was no great difference of current prices over those current in 1888.

It is not a little remarkable that so inconsiderable an increase of exports as 149,000 tons should have been coincident with an increase of nearly 100 per cent. in the price of pig iron all over the country. This apparent anomaly is no doubt largely due to the apprehended scarcity of supplies of raw materials, and to the consequently expected failure of the supply of pig iron to meet the demands. Up to the present time there has been no real famine of either, nor can there well be one of pig so long as the stocks of pig at Glasgow and Middlesbrough are so considerable. But the demand has undoubtedly been in excess of the normal supply. During the first six months of the year stocks were reduced throughout the country to the extent of nearly half a million tons. This fact, coupled with the great advance in prices, was calculated to lead to a large increase of production, and all the more so that one half of the blast furnace plant existing in the United Kingdom at the beginning of the year was returned as unemployed. As a matter of fact, however, there has only been a very limited increase of the number of furnaces in blast, and it is probable that when the returns of production are made up for the year, it will be found that there has been an actual increase of less than 500,000 tons. One explanation of this apparent anomaly is to be found in the comparatively small number of additional furnaces that are available for immediate use. During the last four or five years the number of furnaces unemployed has been practically equal to the number in blast. But many of those furnaces are too far out of repair to be of any use, and most of them would require re-lining, which is a costly and tedious process. If there were any degree of certainty as to the continuance of high prices, no doubt this cost would be undertaken; but pig iron makers do not care to incur the expense of re-lining furnaces that might never be wanted, even if there were no other difficulties in the way. But there are other difficulties, and those, too, of a serious character. The supplies of coke and of certain descriptions of iron ore have been scarcely equal to the demand for some time past. Both have, as a consequence, advanced considerably in price, coke now being quoted at 18s. 6d. to 21s. and Furness ores at 16s. per ton, as compared with 10s. and 11s. per ton some 18 months ago. This will mean a difference by increase of 23s. to 25s. per ton in the cost of producing pig iron, so that the profit goes very largely to the mineral owner, in cases where the pig iron maker has to buy his materials, as he would have to do in the case of blowing in new furnaces, in the open market. If, however, he found himself buying raw materials at current prices, even on short contracts, without being covered by sales of pig, the high profits that now look so probable might easily be converted into heavy losses; and this being so, there is hardly likely to be any considerable increase of production, so long, at least, as raw materials remain so scarce and dear. That they will long so continue is hardly to be expected. There are still abundant supplies of good coking coal in Durham, the Midlands, and South Wales. Undoubtedly, however, the best seams in some of the principal fields have been pretty well exhausted. Calculations made some years ago, by mining experts, indicated that the South Durham coking coal would last for a hundred and fifty years more at least, at the then rate of supply, which did not greatly differ from that of the present time. It is, moreover, possible, by the mechanical treatment of the coal of inferior quality, to adapt a much larger area for coking purposes than was at one time expected. A development of production in this direction may therefore be looked for; but it may not be on a large scale. It would, indeed, be a pity if it were. Coke-makers have for years been carrying on a very lean business. They have not been averaging more than 8s. or 9s. per ton at the ovens, and if this were again to become the normal price, there would be little inducement for fresh hands to go into the business, or for new collieries and coke works to be opened up by those already in it.

So far as iron ores are concerned, there has not been, and there is not likely to be, any scarcity of the inferior ores of Cleveland, Northampton, Lincolnshire, and North Staffordshire. It is in regard to the high-class hematites of the West Coast that a famine may be possible. It is a well-known fact that the demand for such ores within recent years has greatly increased. In 1868 the production of West Coast hematites amounted to 1,893,000 tons, which increased in 1888 to 2,672,000, being an increase of 779,000 tons. In the former year practically no ores of this class were imported into the United Kingdom, but in 1888 something like 3½ millions of tons of such ores were imported from Spain and other countries. In 1868 only 19 per cent. of all the iron made was from hematite ores, whereas, in 1888, 40 per cent. of our iron production was made from them. There has, therefore, been every inducement to develop the production of such ores on the West Coast—the only district in which they are found in any abundance—and yet they have only increased to a comparatively small extent. These facts appear to confirm the current rumours that there is not much likelihood of any great development in this direction, and that a scarcity may actually come about, if it is not already arrived at. There is, however, no danger of our foreign supplies failing if they are well looked after. In the Bilbao district there is still a great supply of Rubio ores available, and new deposits are being constantly opened up. In the South of Spain there are many virgin fields awaiting development, and in Swedish, Lapland, and other districts there are ascertained supplies of enormous extent, so that if the trade is hampered at all by the difficulty of obtaining supplies, it can only be for a short period.

In completing this brief statement of the condition and outlook of the iron industries, we present herewith a few tables that will throw some light on the course of prices. The first of these shows the extremes between the commencement and the end of the year 1889. It will be observed that the greatest amount of advance has occurred where, probably, it was most urgently required—in bar iron and steel rails. Those who have been engaged in these trades for the last five or six years have had a really very hard time of it, and it is well that they should now have a better prospect in view. Much of the difference in price is, of course, absorbed by the additional cost of the pig, which varies between 17s. 4d. in the case of Scotch, to £1 8s. 6d. in the case of hematite iron. Copper and tin have, as will be perceived, fallen in value, while English pig lead shows about the same advance as Scotch pig iron.

The average prices quoted for metals in the first week of January and the second week of December, 1889, were as under:—

	January.	December.	Increase.
Scotch pig	£2 1 6	£2 18 10	£0 17 4
Cleveland pig	1 14 0	3 1 0	1 7 0
Hematite	2 5 0	3 13 6	1 8 6
Cleveland bars	5 2 6	8 15 0	3 12 6
Steel rails	4 2 6	6 17 6	2 15 0
Copper (Chili bars)	77 7 6	49 2 6	-
Straits tin	98 17 6	97 17 6	—
English pig lead	13 5 0	14 2 6	0 17 6

In the next table, the quantity, official value, and the calculated average value per ton of the iron and steel exports of 1888 and 1889 are recorded. The general effect of the figures is to show a considerable increase of both exports and prices, but of course, as already shown, the quantities exported are not in all cases satisfactory. Tinplates, which continue to be practically a monopoly of our own makers, and to be limited mainly to South Wales, show a very substantial increase, both of volume and price, and those who produce their own bars must have done very well.

Statement showing the Quantities and Value of the Iron and Steel Exported in 1889, *compared with* 1888 (1 = 1,000).

	Quantity Exported. 1888. Tons.	1889. Tons.	Value. 1888. £	1889. £	Average Value per Ton. 1888. £ s. d.	1889. £ s. d.
Pig iron	967	1,116	2,052	2,728	2 2 4	2 8 0
Bars, angles, &c.	270	235	1,502	1,496	5 11 2	6 7 3
Railroad	941	998	4,295	4,287	4 11 2	4 5 9
Wire	59	51	793	750	13 8 1	14 14 1
Hoops, sheets, &c.	385	357	3,737	3,798	9 14 1	10 12 7
Tinplates	362	401	5,136	5,585	14 3 7	13 18 5
Cast and wrought, &c.	394	424	4,490	4,940	11 7 9	11 13 0
Old iron	138	134	377	391	2 14 3	2 18 3

Steel manufactures	17	19	517	587	30 8 2	30 17 8

Average Prices of Exports of Iron and Steel, as deduced from the Board of Trade Returns.

	1875.	1880.	1885.	1889.
Old iron	£4·76	£4·78	£3·07	£2 18 3
Pig and puddled	72·80*s.*	63·94*s.*	43·56*s.*	2 8 0
Bar, angle, &c.	£9·87	£7·81	£6·13	6 7 3
Railroad iron	9·29	7·31	5·47	4 5 9
Wire (except telegraph)	18·48	13·99	12·51	14 14 1
Sheets and plates	15·18	10·67	8·13	10 12 0
Galvanised	24·46	18·33	13·41	—
Hoops	11·16	8·46	6·69	—
Tinned plates	26·64	20·48	14·84	13 18 5
Other iron	18·10	13·75	11·53	11 3 0
Steel ingots and blooms	—	6·28	5·05	—
Steel bars	36·31	28·24	22·01	—
Steel sheets	32·99	21·91	12·52	—
Steel manufactures	75·07	57·97	31·43	30 17 8

These figures are useful as affording some idea of the enormous extent of the reduction that has occurred in the average values of all the leading descriptions of iron

Digitized by Google

and steel. The tendency was almost continuously downward for fifteen years until last year. This year prices have recovered very largely, but for many descriptions they are still lower than they were in 1883, and much lower all round than in 1873.

The stocks of pig iron in stores at the commencement of 1889 and at the end of December, in the three principal districts, were as under:—

	January. Tons.	December. Tons.	Decrease. Tons.
Scotland	1,031,748	943,775	87,973
Cleveland*	472,628	239,888	232,740
West Coast	429,639	380,310	49,329
Totals	1,934,015	1,563,973	370,042

The above figures are very healthy indeed, and no doubt it will be found, when the full returns for the year are made up, that the decrease of stocks in the hands of makers has been considerable, probably sufficient to bring the total decrease of stocks to some half a million tons. It is, however, impossible to say what may be the increase of production. In Scotland the production of pig has actually been about 29,000 tons less than in 1888, but this is not likely to have been the case in other districts.

COAL.

Although it will still be several months before the actual production of coal for 1889 can be ascertained, it can be no secret that it will be considerably in excess of that of 1880, which amounted to 169,935,000 tons. There has, indeed, been an increase of consumption in every direction. The quantity of coal exported and shipped for the use of steamers engaged in the foreign trade has exceeded by more than 2½ millions of tons the consumption of 1888. The railways at home, and the steamers engaged in the coasting trade, having done a much larger business than in the previous year, must have consumed more fuel. In the iron, steel, foundry, shipbuilding, chemical, and other trades, a much larger volume of business has been done, calling for a much more considerable quantity of coal. Domestic consumption is a constantly increasing quantity, and has this year increased quite as much as usual, people buying more coal, as they can better afford it. It would therefore probably be a safe thing to estimate that the consumption of British coal in 1889 will not be less than 175 millions of tons, of which the enormous quantity of 37 millons, or over 21 per cent., has been sent abroad, either for the consumption of foreigners, or for the use of our steamers in the foreign trade.

The European demand for British coal has now assumed portentous proportions, the quantities exported to the principal countries in 1888 and 1889 having been as under (1=1,000):—

	1888. Tons.	1889. Tons.
France	3,824	3,640
Italy	3,263	3,323
Germany	2,814	3,253
Sweden and Norway	1,793	2,145
Russia	1,501	1,758
Denmark	1,183	1,269
Spain	1,476	1,616
Holland	258	447

Our principal exports to countries out of Europe have been as under:—

	1888. Tons.	1889. Tons.
Egypt	1,295	1,333
Brazil	547	680
British East Indies	1,203	1,121
Turkey	398	398

The prices of coal have hardened steadily during the second half of the year, and are now fully 30 to 40 per cent. higher than they were in the month of January.

SHIPBUILDING.

No branch of the trade of the United Kingdom has been more active during 1889 than that of shipbuilding, which has, of course, created an equally active demand for shipbuilding materials, and especially for iron and steel and machinery. The total tonnage launched during 1889 has been returned at 1,286,679 tons, but as it seldom happens that the total turn-out of the year is ascertained at this early period, the aggregate is likely to be about 1,300,000 tons, which is greatly in excess of the quantity built in any former year except 1883, when the total rose to 1,250,000 tons. As only some 100,000 to 150,000 tons are ordinarily built for foreigners, the greater part of this vast tonnage must be added to the British register, and it is probable that after all wrecks and replacements have been allowed for, the actual addition to the register for 1889 will be some 700,000, which is an entirely phenomenal addition. The Tyne, Wear, Tees, and Hartlepool have supplied 718,000 tons towards the total of 1889, and the Clyde has followed with 335,000 tons. Next in order come Belfast with 80,000 tons, and the Mersey with about 35,000 tons. Prices have been well kept up, and the returns of the shipbuilding actually in hand appear to promise another prosperous year for this great industry. In Germany, Holland, and other European countries the increase of shipbuilding in 1889 has been important.

* Makers' stocks included.

SHIPPING.

One very satisfactory feature of our business for the past year is evidenced by the fact that, in spite of all the pessimistic talk that we hear from time to time as to the possibility of having to yield up a share of our shipping supremacy to other maritime nations, we still continue to carry our trade in much the same proportions under our own flag. The shipping entrances and clearances in 1889 amounted to a total of 56,594,000 tons, of which 14,080,000 tons were foreign vessels, being rather under 25 per cent. In 1887, the total entrances and clearances were 51,511,000 tons, of which 12,727,000 tons were carried in foreign vessels, being just about the same percentage of the whole. But it must not be forgotten that there was a much keener competition, and consequently much lower rates in 1887, so that foreign vessels had not the same chance as in 1889, when the freights for British bottoms took a higher range. It might, therefore, be expected that in 1889 foreign ships would have a much better chance of competing successfully, all the more so that there has, in not a few cases, been a difficulty in getting English ships at all. The largest amount of foreign tonnage that entered and cleared in 1889 carried the German flag, the next largest the Norwegian, and the next largest the Dutch. But although Germany has of late years made great efforts to increase her merchant shipping business, it is remarkable that, of the 5,086,000 tons of entrances and clearances from and to Germany in 1889, only 2,753,000, or little more than one-half, was German tonnage.

The countries with which we have done our shipping business during 1889 compare very favourably with those shown for previous years. So far as our export trade is concerned, which is the main factor, it appears that we increased our clearances for our principal markets in the proportions that follow:—

Exports, as represented by Shipping Clearances in

	1889. Shipping Tonnage.	1887. Shipping Tonnage.	Increase in 1889. Shipping Tonnage.
Germany	3,278,000	2,730,000	548,000
France	3,205,000	3,298,000	—
Spain	1,161,000	1,058,000	103,000
Italy	2,111,000	1,957,000	154,000
North Russia	1,203,000	1,080,000	123,000
South Russia	196,000	67,000	29,000
Sweden	1,132,000	935,000	197,000
Holland	1,672,000	1,377,000	295,000
Turkey	405,000	363,000	40,000
Egypt	829,000	776,000	53,000

There has, however, been a falling off in our clearances for the United States, France, Roumania, and Austrian territories, while to Belgium our clearances have been almost stationary. The reduced shipments to the United States are the most serious of all. In 1887 they were 3,211,000 tons, whereas in 1889 they only amounted to 2,970,000 tons, showing a falling off to the extent of 241,000. Much has been made of the fact that the present revival of trade has been in no degree due to the United States. These figures show, so far as they go, that, so far from that having been the case, there has been a substantial falling off in our shipping clearances to that country; and the Fair Traders are not likely to be comforted when they find that for the same periods our entrances into British ports from the States have advanced from 4,307,000 tons to 4,710,000 tons. This increase was, however, almost inevitable. The United States supply, not only the great bulk of our imported food supplies, which we buy there because we cannot buy cheaper elsewhere, and therefore buy in our own interest entirely; but they furnish the raw materials of some of our leading industries, and notably those of the cotton manufacture, which we re-export to other countries in the finished condition.

To our newer and less developed markets we owe a great deal of the demand that has stimulated the recent revival of trade. The Returns show that our shipping clearances to Brazil have advanced from 539,000 to 712,000 tons, to Chili from 183,000 to 259,000 tons, and to other countries, such as the Argentine and other South and Central American republics, from 1,428,000 to 2,165,000 tons. This last is a very hopeful feature indeed. South and Central America are now, next after China and Japan, the most promising neutral markets in the world. They do not to any great extent manufacture themselves, and they are every year increasing in importance. When we use the term neutral markets, we do not, of course, include our own colonies, to which the shipping clearances have been 5,238,000 tons—a falling off as compared with 1888, although a substantial improvement on 1887. This falling off is equally apparent in the East Indies, our Australasian colonies, and the Dominion of Canada, while, as regards the West Indies and our other colonial possessions, there has been a solid advance.

The shipping industry, which is always in a flourishing condition when the trade of the country is generally prosperous, has, as might be expected, responded fully to the upward and progressive movement in commerce and industry generally. The total tonnage of British and foreign vessels that have entered British ports during the eleven months of 1889 has been as much as 26,131,000 tons, as compared with 24,763,007 tons in 1888 and 23,910,000 tons in 1887. There has, therefore, been an increase of nearly 10 per cent. in 1889 over the corresponding period of 1887, which must be regarded as a satisfactory advance. There has been an equally remarkable advance in the clearances from British ports, which amounted to 30,464,000 tons in 1889, as compared with 29,055,000 tons in 1888 and 27,601,000 tons in 1887, thus showing an increase of 2,863,000 tons, or again about 10 per cent. over 1887. It is hardly necessary to remark that this increase has been an increase of volume entirely, and it therefore proves that our prosperity is not merely due to an increase in prices, but is an actual development of demand and of production all round.

THE LEATHER TRADES.

The old adage that there is "nothing like leather" appears to be once more verified in the conditions of the leather trade during the past year. To begin with, our imports of the raw, or rather dressed, materials have been greater than in any former year, reaching 96,250,000lb. as compared with 78,000,000lb. in 1887. We have also imported 1,469,300 dozen pairs of gloves, and 92,551 dozen pairs of boots and shoes. For these several items we have had to pay a little bill of over eight millions sterling, which is a pretty good thing for the French, who have mostly supplied us with the goods in question. Our showing on the other side of the account does not compare favourably with that just recorded. Our exports of leather, both unmanufactured and in the form of boots and shoes, amounted to only £3,207,000, which is considerably less than one-half the value of our imports. In all departments our exports of leather show a decrease as compared with 1888. The decrease, however, is not so serious as to justify any apprehension that the trade is going to the dogs, although there can be no doubt that, with the cheaper labour of France and other countries, and their more delicate methods of manipulation, it is not easy for English leather merchants or bootmakers to hold their own in the export trade.

MINOR INDUSTRIES.

When miscellaneous and minor industries are considered, the record for 1889, although undoubtedly leaving little to complain of, has not been so uniformly progressive as in the cases of the great staple industries with which we have already dealt. As regards some of them, indeed, there has been a considerable falling off, as the following figures show (1=1,000):—

Exports from United Kingdom.

		1888.	1889.
Boots and shoes	doz. pairs	606	605
Alkali	cwts.	5,826	5,570
Bleaching powder	"	1,453	1,384
Gunpowder	lbs.	12,675	10,026
Bags and sacks	doz.	3,357	2,873
Plate glass	sq. feet	3,966	3,524
Leather, unworked	cwts.	148	130
Seed oil	tons	71	63
Paper, writing, &c.	cwts.	731	644
Paperhangings	"	58	56
Other papers	"	214	196
Soap	"	452	448

Here we have a dozen important industries in regard to which the exports show a falling off as compared with 1888. In most of them the decline is immaterial, and in reference to most it will be found that prices have improved, but the revival of business is still one that is not universal, and it must be carefully tended if it is to be taken advantage of.

IMPORTS AND EXPORTS.

The year 1889, so far as our imports and exports are concerned, has been by far the most prosperous year that British trade and industry have ever known. Probably not many people have stopped to realise the fact that our foreign trade in 1889 will amount to 117½ millions more than that of 1886. These two years indicate the high and low water marks of British trade with foreign countries—1886

IMPROVED SCREWING MACHINE.

CONSTRUCTED BY THE OERLIKON MASCHINENFABRIK, ZURICH.

(*For description see opposite page.*)

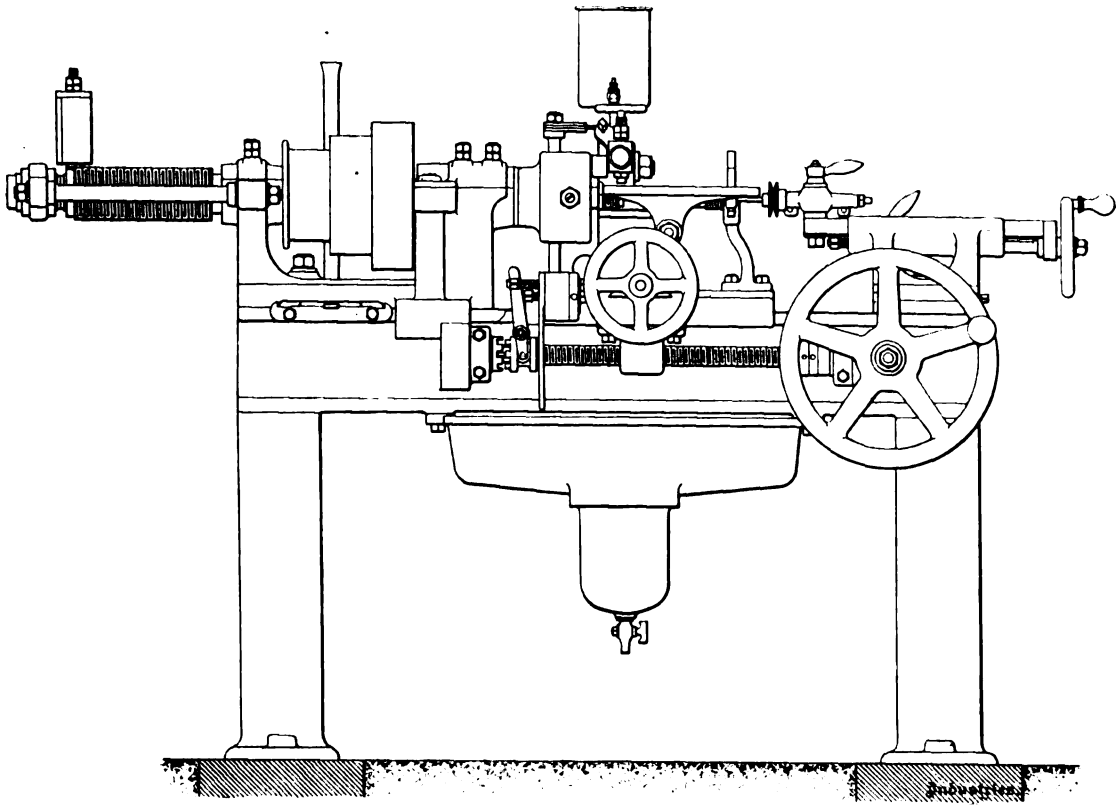

FIG. 1.

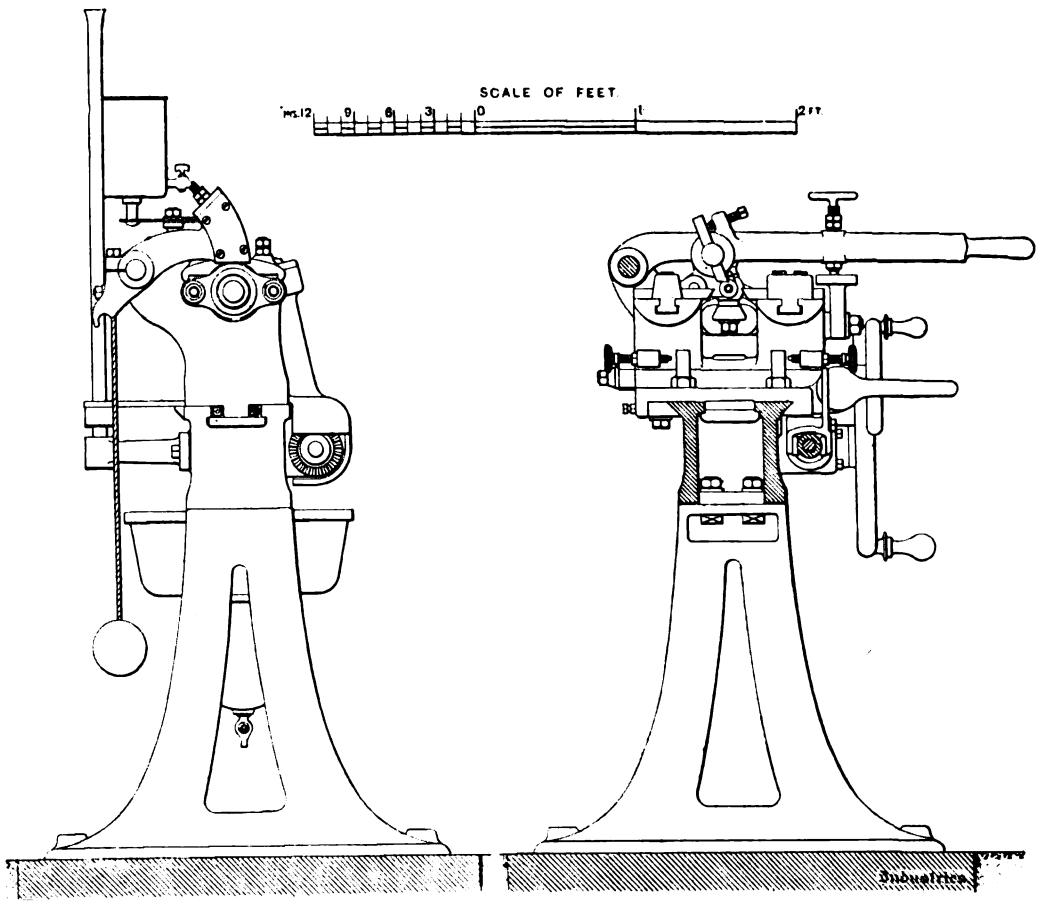

FIG. 2.

FIG. 3.

having been the year of lowest prices and smallest trade, and the year 1889, on the contrary, carrying us on the crest of a wave of bounding prosperity, which tends no one knows whither.

Up to the end of November, the total value of our imports amounted to 389¼ millions. If the value of the December imports be taken at the same figure as those of November—and they should be somewhat more if the daily average is much the same, seeing that there is one day more in December—it would follow that our total imports for the year will amount to rather over 430½ millions, which is an increase of 43 millions on those of 1888, 68¼ millions on 1887, and 80¾ millions on 1886. The total exports for 1889, assuming December to be again dealt with in the same way, will amount to 249½ millions, which is again an increase of 15¾ millions on 1888, 28 millions on 1887, and 37 millions on 1886. Our imports have, therefore, increased to the extent of more than twice the value of the increase of exports. This increase is largely due to the greater imports of breadstuffs, which are not, of course, directly a source of wealth, but it is, nevertheless, important to observe that we only buy our food supplies from abroad to the extent that we do because we cannot do better otherwise or elsewhere. The increased preponderance of imports over exports is a matter that is likely enough to fill with apprehension those who calculate that trade should be evenly balanced as between the two. It will be observed that for the past year there is a difference of 181 millions sterling, or, put in another way, that the difference is equal to 27 per cent. of the whole sum of both. The truth, therefore, seems to be that our imports are far on the way to doubling our exports, and it will no doubt be a hotly contested point among the political economists and others how this comes about, and how far it is hurtful or otherwise to British trade. It must never be forgotten that we have to reckon our imports plus the cost of ocean freight, whereas this item is not any part of the official cost of our exports. If we are to equalise the two for purposes of comparison, we must deduct some 70 millions sterling from our imports for this consideration, which would reduce the difference to little over 100 millions. There are many items that go to make up this difference, which have been again and again pointed out. But as regards the special circumstances of the year 1889, it must not be forgotten that imports have gone, in a material degree, to make up the sum of the trade that has been done at home to a very exceptional extent during the current year. To take one example only. We have this year imported nearly half a million tons more of iron ore than in 1888. This iron ore has been manufactured first into pig iron, and afterwards into rails, plates, bars, angles, &c., which have been used in our shipbuilding, railway, and other home trades, that do not figure at all in our export returns. Many other cases might be quoted to prove that imports and exports do not always run so far on all fours that an exact or relevant comparison can be made between them. And one fact stands out more prominently than any other—that, whatever the ultimate result may be, the differences to which attention has been called are strictly compatible and coincident with a rare degree of general prosperity.

In the exports of British and Irish produce, the total increase of value for 1889 has amounted to £12,224,000. The principal item of increase occurs under the head of raw materials, which embrace almost solely coal and wood. In coal alone there has been an increase to the amount of £3,235,000, as compared with a total increase for raw materials of £3,250,000. This has been largely an increase of price, although the actual quantity exported has advanced in 1889 to 26,737,000 tons, from 24,737,000 tons in 1888 and 22,363,000 tons in 1887. There are economists and others who are rather disposed to deplore the export of raw materials, which are, beyond all doubt, a substantial foundation, if not the main foundation, of our industry; but the period when we are likely to feel the effects of a scarcity of fuel is still a long way off. On the whole, however, it is perhaps more satisfactory to turn from raw materials to metals, machinery, and mill work, the exports of which for 1889 show an increase of £5,260,000 as compared with the previous year. This, again, is largely an increase of price, inasmuch as the actual increase of quantity only amounts to 202,000 tons as regards metals. Considering the great activity that has prevailed for months in the iron and steel industries, a much larger export might naturally have been looked for; but that activity has been largely created by an increase of demand at home. As this demand is likely to be more easily satisfied than a general demand from abroad, a larger increase of the latter would have been more encouraging.

There is one department of our export trade that has not yet been either dealt with or included in any of the figures that have gone before—namely, our exports of foreign and colonial produce. This is an important branch of commerce, inasmuch as it provides employment for a large part of our shipping, but it is not of much interest or value as affecting any other home industry. The re-exports of such products in 1889, reckoning December at the same figure as November, will be about 64½ millions, or, roughly, half a million more than the value of 1888. Adding this to the other items of foreign trade, the total comes out as 744 millions, which is just 12 millions in excess of the next best year in the history of our foreign trade—that having been 1883.

HOME DEMANDS.

Hitherto we have dealt with the foreign trade only. But it has been remarked that one of the most notable

Digitized by Google

features of the revival of trade in 1889 has been the increase of home business. This increase has been chiefly reflected in the traffic returns of the railway companies, which do the greater part of the carrying trade at home. But it is also clearly established by the returns of the coastwise shipping trade, which show for 1889 an increase in entrances and clearances of 3,772,000 tons as compared with 1887. This is a remarkable increase, representing as it does a much more considerable weight of actual traffic; and, taken in conjunction with the railway returns, proves that the home demand for commodities has been much greater during 1889, although 1887, as we have already pointed out, was a prosperous year compared with 1885 and 1886. One feature of our coasting trade is that there has been a falling off, as between 1889 and 1887, in the shipping entries from Ireland, although there has been a substantial increase in the clearances to that country. There is still a certain proportion of our coasting trade carried in foreign ships, but it is only a fractional part, and it is every year getting smaller.

One of the most effective signs of the improvement of trade is the greater activity that exists in reference to the development of new industrial enterprises, both at home and abroad. This development, as regards each of the last two years, may be estimated by the following figures, which show the plans deposited for Bills coming before Parliament during the Session of 1890, compared with those for the previous Session :—

Bills	Session of 1890. Number.	Session of 1889. Number.
For Railways.....	67 ...	47
„ Tramways	12 ...	14
„ Miscellaneous..... ...	59 ...	54
„ Provisional Orders, Miscellaneous	35 ...	46
„ „ Electric lighting	159 ...	—
Total	332	161

It appears, therefore, that there will be just about double the amount of Private Bill legislation required in Parliament this year that obtained in 1888, which means, of course, that a much larger amount of work must be provided throughout the country in carrying out the various enterprises that are the subjects of these applications.

LABOUR DISPUTES.

The business of the past year has been a good deal interfered with by strikes and rumours of strikes, which are generally got up when trade has begun to mend. The workmen are in some cases less reasonable than they should be, most often from ignorance of the real facts. They appear to assume that, directly the price of a commodity improves, their employers enter into the full possession of the difference between the old and the new price. There could, however, be no greater fallacy. As a rule, manufacturers are working more or less under old contracts at old prices, and have probably only a limited part of their products free for sale. Not only so, but they have generally to pay an increased price for raw materials, which may, and in many cases actually does, absorb the greater part of the nominal difference between the old price and the one on which the men take action. The case of the iron trade illustrates this point very aptly. The price of Cleveland pig has been advanced from 25s. to 30s. per ton on the prices current up to a year or so ago. But against this the manufacturers have to pay some 10s. more, at least, in the price of coke, and probably 4s. to 6s. more in respect of other increased charges, so that all the difference that would come to the maker who bought his materials in the open market at current rates would be under 10s. per ton, and this is to be set off against years of depression, when he was making hardly any profit at all. The same complexity of arrangements runs through all other leading industries.

We intend next week to publish special reports dealing with the progress in engineering, electricity, and chemistry during the past year.

WIRE STRAIGHTENING MACHINE.

There are numerous uses for absolutely straight rods of various diameters in the construction of many classes of machines, but their production has always been an expensive process. Even after great care has been exercised, the result has not always been satisfactory, and it is quite certain that any rapid method of straightening wire or bars will be of great service to a large number of manufacturers. In the machine illustrated above the general principles are those embodied in a patent of Messrs. Wood & Smith, but certain additional features have been added by Mr. Barraclough, the head of the firm of Messrs. Barraclough & Co., Limited. The machine consists of three parts—the straightening, feeding or delivering, and the cutting. The straightening head A (Fig. 2) revolves in suitable bearings at a high velocity, and is provided with dies B, now preferably made of phosphor bronze and with semi-circular heads. These dies can be set up by means of the screws shown, and when set can be firmly locked in position. They are, when working, arranged so as to bend the rod alternately in each direction to such a degree that when it leaves the head all the kinks are effectually removed. In addition to this the rapid rotation of the die surfaces round the rod in its transit gives a polish to the latter which obviates in many cases any necessity for turning.

The second part of the machine is that which delivers the rod. This consists of two cams C C^1 set in opposite directions to each other. These press against a bowl in the lower part of the levers D D^1, and are so constructed that at each revolution they give a double motion to the latter. That is, they move the levers longitudinally and lift the lower end so as to cause a jaw fixed on the upper end of the levers to nip the wire against a suitably arranged jaw. These operations take place in the reverse order to that named, the round of operations being as follows: Assuming that the lever D is as near the straightening head as it can be, the cam C causes it to oscillate on the centre rod E, and thus nip the wire. The continued revolution of the cam then moves the lever D towards the delivery end for the length of its throw—4in.—when the wire is released by D, the cam being shaped to effect this. At this moment the second lever D^1, worked by its cam C^1, is at its innermost point, and grips the wire as it is dropped by D, beginning immediately to move towards the delivery end. In this way the cams work alternately but continuously, and except the slight pause, which is designedly given at the end of the stroke of each cam, the progress of the rod through the machine is continuous. This is a very simple and ingenious contrivance, and is practically effective.

The cutting apparatus is placed at the end of the machine, and consists of an upper fixed jaw and a lower sliding one, each carrying a cutter blade. The period at which one blade advances upon the other coincides with the slight pause made in the traverse of the wire as described. The slide is raised by means of a stud wheel F, the rotation of which can be regulated by change wheels, and which is fitted with one or more studs, as desired. These, in their revolution, raise the sliding cutter and cut the rod to any required length. It is easy to see that a modification of the rate of revolution of the stud wheel will alter the length cut off, and this is further aided by the employment of stops G, which enable the primary length moved at each traverse of the grips to be altered as desired. These stops are fixed, as shown, on a square bar placed at the upper part of the machine above the cams, and divided or ruled in fractions of inches or other standard measurement. By this combination practically any length from 4in. upwards can be cut.

The chief improvements made by Mr. Barraclough consist in a special arrangement of driving. As originally designed, the straightening head and delivery cams were driven separately, but they are now driven from one point in the centre of the machine, as shown, the speed of the cams being reduced by the use of three pairs of wheels and pinions compactly arranged. The machine is made in three sizes, the first of which deals with material from 7 B.W.G. to $\frac{7}{16}$in. diameter; the second from 7 to 18 B.W.G.; and the third from 18 B.W.G. to finer sizes. It effectually deals with the hardest steel, and we saw some specimen rods produced from a reel of wire on the machine which were quite fitted for immediate use without further preparation. In conclusion, it may be said that the general construction is satisfactory and the workmanship good, and the machine is likely to prove a valuable adjunct to machinists and others.

WIRE STRAIGHTENING MACHINE.

Constructed by Messrs. T. Barraclough & Co, Machinists, Manchester.

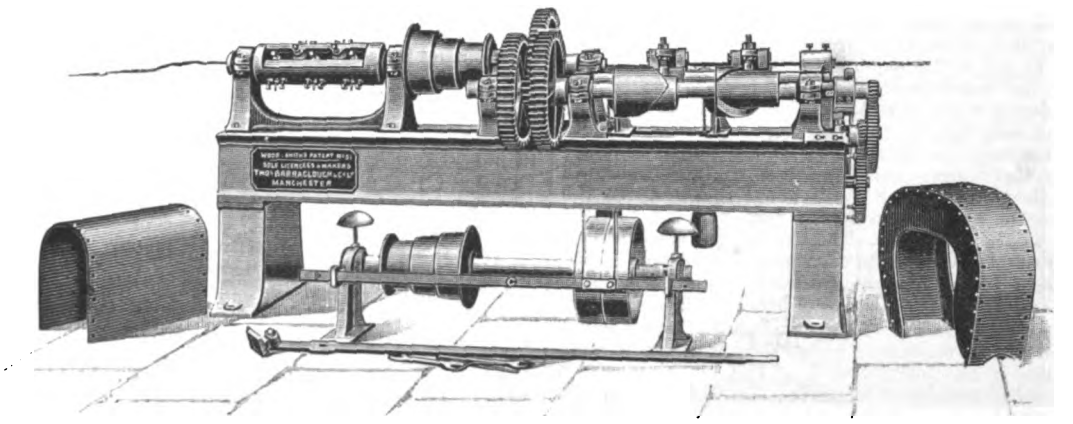

Fig. 1.—General View.

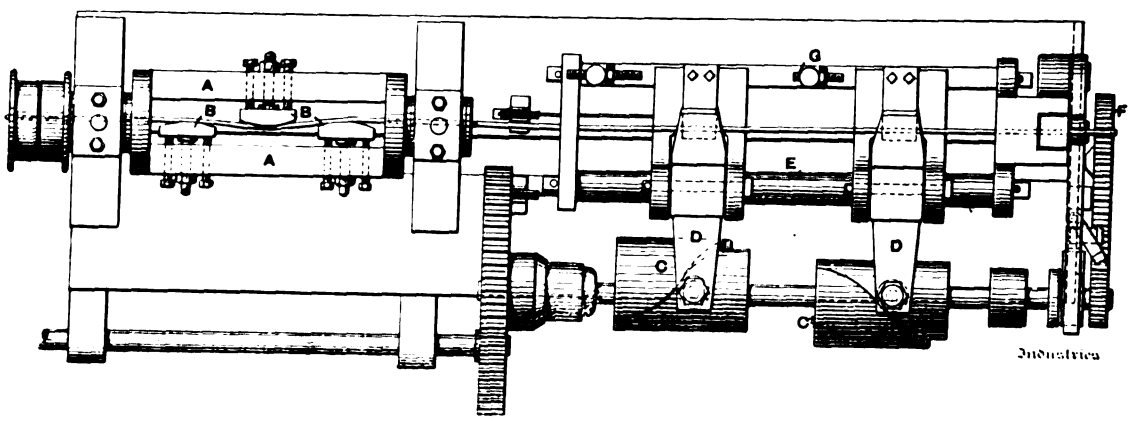

Fig. 2.—Plan.

IMPROVED SCREWING MACHINE.

We illustrate on page 4 a useful screwing machine of 8in. centres, exhibited at the late Paris Exhibition by the Maschinenfabrik Oerlikon, Zürich, Switzerland. Fig. 1 shows a front elevation; Fig. 2 an end elevation, as seen from the tail-pin end; and Fig. 3 a section through the bed looking towards the loose headstock. The general construction of the machine is clearly shown in the engravings. Stops are provided for all the motions, and the machine altogether is a good example of recent Continental types.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 9.)

PARIS, 31st December, 1889.

IRON.—That the year 1890 will begin in circumstances favourable to the iron trade none doubt, but the view generally taken of the near future of that trade is probably destined to end in disappointment. The present position is likely to be maintained. Further improvement in any marked degree is not to be looked for. This is, at least, the opinion of some who are in a position to judge accurately of the tendency of events. There are no grounds for believing that a large quantity of iron will be consumed in Paris in the year on which we are about to enter. In the provinces the present activity may be kept up, but the demand will be easily met. The exceptional circumstance of heavy purchases on German account is not likely to be repeated in 1890. We may reasonably hope for a steady amount of business, but there will be no "boom."

METALS.—The future of the metal market is just now a matter of anxious concern to many. What is to be the course of business in the early months of 1890? This question is being asked with much misgiving as to the answer. As for copper, no one believes that the present prices can be maintained much longer. But the case is different for tin. It is the common opinion that a "ring" exists to run up the price of that metal. Zinc can hardly continue its upward course much farther, as the high prices have greatly restricted consumption; but as there are no stocks in hand, a speedy relapse is improbable. As for lead, the conditions of trade are such that the market cannot be greatly disturbed by any possible combination.

PREFERENTIAL RAILWAY RATES.—A strong agitation has been set on foot by the colliery owners of the North for the abolition of the preferential railway rates which favour the import trade in coal to the injury of the home coal mining industry. The advantages afforded the importers by these rates, they say, neutralise the effect of the protective duty imposed in the interests of the home trade. Examples are given to show that English coal is carried over distances of 50, 70, and even 100 kilometres practically free of charge. It seems likely that the agitation, which is well organised and persistent, will effect its purpose. This is a matter of considerable importance to the trade in English coal.

SHIPBUILDING.—The additions about to be made to the French Navy will tend to impart vigour to the iron trade. The Minister of Marine has, within the last few days, signed contracts for the construction of two armoured cruisers and three large ironclads. The Chantiers de la Gironde and the Forges et Chantiers de la Mediterranée will each build one of the former. The contract price is £344,000. One of the ironclads, which are to be of the Admiral Trehouart type, and of 6,700 tons displacement, is to be built by the Forges et Chantiers de la Mediterranée; the other two will be built by the Chantiers de la Loire. The contract price for the first is £492,960, and for the others £488,960.

THE MEASUREMENT OF HIGH TEMPERATURES.—At the last meeting of the Physical Society of France, M. Le Chatelier showed a new apparatus for measuring high temperatures, which will no doubt be capable of extensive application. Its action depends on the rate of increase of the resistance to the flow of gases through capillary tubes, according to the temperature of the tube. The experiments have shown that with a capillary silver tube ·43mm. in diameter and ·2m. long a certain amount of air at constant pressure took 80, 115, 270, 310, and 427 seconds to pass through it at temperatures of 15°, 100°, 320°, 500°, and 700° C. respectively.

THE TELEPHONE BETWEEN ROUEN AND PARIS.—The iron telephone wire between Paris and Rouen has lately been replaced by a bronze wire, and the hearing powers have been consequently much improved. It has, therefore, been decided to make the same change on all the trunk lines, and the next alteration will be on the Reims and Paris line.

THE INTERNATIONAL TELEGRAPH CONGRESS.—The next meeting of the International Telegraph Congress will be held at Paris in the year 1890, during the month of May. The president for the year will be the Director of Posts and Telegraphs.

BERLIN, 30th December, 1889.

BOURSE.—The colliers' strike in Belgium has given fresh impetus to the market in coal securities here. Within the last few days the demand for shares in colliery companies has become very brisk. It is significant of the situation of the coal mining industry that the price of shares in such companies has increased from 50 to 100 per cent. since the beginning of the year.

IRON.—The production of pig iron in Germany, including Luxemburg, in the month of November amounted to 389,570 tons, against 343,971 tons in the same month of last year. This brings up the total production for the first eleven months of the year to 3,996,435 tons, against 3,874,618 tons in the corresponding period of 1888. The output of the furnaces is still in some degree restricted by the short supply of coke. The exports in the first three quarters of the year 1889 were—For pig iron, 167,532 (121,191) tons; for finished iron and steel, 597,545 (636,409) tons; and for machines, 54,614 (57,231) tons; the figures within parentheses being those of the corresponding period of 1888.

THE NEXT INTERNATIONAL EXHIBITION.—There is a strong feeling in German commercial circles that the next great International Exhibition should, in the interests of German trade, be held in Berlin. This feeling has already shown itself in action, a number of influential persons in various callings and positions having met to discuss the question and to devise measures for promoting the scheme. The project is said to be regarded with favour in high official quarters.

DYERS' PRICES.—The Berlin woollen yarn dyers have resolved to advance their prices for all colours from the 1st January, 1890.

CEMENT PRICES.—The proprietors of the sixteen cement works who constitute the South-West Cement Manufacturers' Syndicate have announced an advance of 4½d. per cwt. in the price of their produce from the 1st January, 1890, to cover the additional cost of fuel occasioned by the rise in the prices of coal.

NEW QUICK-FIRING GUN.—The Gruson Ironworks Company have, it is said, purchased the patent rights of a new quick-firing gun. This gun, which is the invention of a Swedish officer, is said to be superior to any yet in the field for simplicity of construction.

STRAW HATS AND BONNETS.—The strike of the hat and bonnet makers, which is being maintained chiefly by contributions from abroad—England, France, Denmark, Switzerland, and the United States of America having each sent considerable sums for the support of the 800 men and women out—has directed attention to the export trade in straw hats and bonnets. The exports in the first ten months of the current year amounted to 2,430,753 articles. France is the largest buyer, 1,451,053 being set down to French account. English buyers took only 38,370. These figures relate only to the untrimmed articles. Of trimmed straw hats and bonnets there were exported 501,955, of which English customers took 8,983, while the French purchased only 3,807.

VIENNA, 30th December, 1889.

COALS.—The coal trade continues to be extraordinarily animated. Especially in Western Bohemia is the demand for export very brisk, on account of the great quantities which go to Saxony, where many factories, at other times procuring Westphalian coals, now buy from Bohemia. The traffic suffers from the want of rolling stock on the Bustehrad and Aussig-Teplitz railways. The Bustehrad Railway has just ordered 600 coal cars.

IRON.—The favourable tendency still prevails in the iron market, and in several branches prices are advancing. The Bohemian rolling mills have raised the price of tinned sheets by 15fl. per ton. Pig iron is in brisk demand. Last week two general meetings of the shareholders of large ironworks have taken place. The first one—that of the Egydy Works—voted the proposed dividend of 3½ per cent.; and the other, of the Manufactory of Arms, a dividend of 27 per cent.

IMPORTS AND EXPORTS.—The value of exports from Austria during the first nine months of the year 1889 has exceeded the value of the exports during the same period of 1888 by 5·8 per cent. The country which has increased most is France. The following table gives a list of exports:—

	1888. Tons.		1889. Tons.
Sugar	96,595	...	142,378
Beer	33,165	...	38,023
Spirits	17,762	...	11,803
Flour	131,135	...	136,637
Iron ore	27,628	...	62,376
Bar iron	7,798	...	6,509
Pig iron	6,555	...	4,667
Waggons	1,972	...	132
Tinplates	1,447	...	1,245
Boilers	46	...	189
Machines	6,785	...	8,303

The imports have increased by 8 per cent. The following table gives the details:—

	1888. Tons.		1889. Tons.
Coal	1,980,590	...	2,327,186
Coke	98,637	...	142,376
Pig iron	48,883	...	67,115
Manufactured iron	4,342	...	7,900
Wood wool	80,452	...	91,091

THE SITUATION OF THE AUSTRIAN MONTAN INDUSTRY IN 1889.—The other day there was a meeting of the Montanverein, when Prince Salm-Reifferscheid was in the chair. The situation of all branches has become better. The perception of mutual interests has rendered the best service to the Austrian Montan iron and machine manufacturers, and it has been also extended this year to some refined iron branches, as, for example, wire nails. Up to the present the syndicate has omitted to increase the prices over the limit. It is a fact that the higher selling prices are balanced by higher production prices. The fixing of the wages was essentially influenced by the strikes. The programme of the Montanverein for the next year contains the solution of two questions: (1) To remove the want of rolling stocks of the railway, which is a steadily increasing hindrance to the trade; and (2) the regulation of the value and its reaction to the industry.

INDUSTRIES IN HUNGARY.—The number of new manufactories in Hungary steadily increases. The new concerns belong to different branches of industry, but in all cases the Hungarian Government has granted extensive favours to the promoters. The number of new factories is not yet exhausted, and many projects are in consideration.

BRUSSELS 31st December, 1889.

THE COAL MARKET.—The coal market continues to be very animated. The prices are continually increasing, and the country is being sought through diligently by foreign buyers for the purpose of finding some coal which has not already been disposed of. The whole production of domestic heating coal is being sold at 25fr. The transport of coal over the iron roads continues to show great activity, and the amount carried by the State Railways compares favourably with that carried this time last year. The strike which has lately been raging has done great harm to industry, particularly in the district of Charleroi.

THE IRON MARKET.—The prices of the finished products are firm, and correspond favourably with those of pig iron and coal. However, it gives the manufacturers some anxiety to see the prices of these raw materials going higher still. The State contracts have given a good deal of work to many shops, but the high price of sheets does not allow of much profit. At a meeting of manufacturers last week sheets and plates were fixed at 21-22fr. as a base. Steel sheets were increased in price by 2fr.

FLAX AND LINEN.—In the principal linen and flax markets there are strong complaints of the stagnation of business. There are several causes for this state of things, chiefly, of course, that the buyers in the Flemish markets, who are principally English and Irish spinners, are at home at present.

NEW TRAMWAYS.—The town authorities of Brussels are about to build a new tramway to connect the Palace Square at the centre of the town with the Luxembourg Station. From the Bourse to the corner of Montagne Street the carriages will be run by electricity, and from there to the end of the journey a steel cable will be employed to help it to mount the rise of 40 metres at a gradient of 20 per cent.

DÜSSELDORF, 31st December, 1889.

COAL.—The report presented to the members of the Düsseldorf Exchange at their ordinary general meeting, held on the 19th inst., at the Hotel Heck, gives some interesting information concerning the state of the coal trade. According to this report, the total production of coal in the Dortmund district, in the first nine months of the year, amounted to 24,515,387 tons, an increase of 1·03 per cent. relatively to the corresponding period of last year. But the number of hands employed had increased 8·6 per cent. Bearing this fact in mind, and taking account of the augmentation in the rate of wages, we see that a large increase has taken place in the cost of production. The small additional output was, however, far from sufficient to meet the growing requirements of consumers; consequently we find a largely augmented import trade. For the first nine months of the year the total imports of foreign coal amounted to 3,342,199 tons, an increase of 50·28 per cent. relatively to the corresponding period of 1888. Of these imports 2,492,143 tons were received from England, a quantity greater by 101·6 per cent. than that of last year. The imports since September have gone on increasing. On the other hand, the exports of German coal to Holland, the chief foreign market for the Westphalian producers, have fallen off considerably. Of course, in a state of things such as is here indicated, prices have risen greatly. What the increase in this direction has been is shown in the report in question by the figures relating to gas coal, dry-burning coal for industrial uses, and blast-furnace coke. In the course of the year the first has risen from 9s. to 16s., the second (roughs) from 6s. 7d. to 12s. 6d., and the third from 10s. to 25s. 6d. a ton. The increase in the cost of coke is remarkable, and it is a fact of great, if not paramount, importance in estimating the situation of the iron trade. At the present moment the tendency is still strongly upward.

IRON.—The year which begins to-morrow will find the iron trade in excellent circumstances, at least in so far as the near future is concerned. The blast-furnace owners have sold nearly the whole of their possible output in 1890. Some of the steel makers have already covered the whole of their requirements for raw material in the coming year, and all manufacturers of finished produce have booked sufficient orders to keep them occupied till the end of June. The upward movement in the prices of pig seems to have come to an end, at least till another considerable advance takes place in the foreign markets. For finished iron there is a rise of 20s. a ton to record in plates and sheets. After this the market is likely to remain steady for some time to come.

RAILWAY SLEEPERS.—The recent order of the Minister of Public Works relative to railway sleepers is one of the many events which have happened of late to promote the interests of the iron manufacturers. According to this order, the length of all sleepers, of wood as well as of iron, is to be henceforward 270 centimetres instead of 240 centimetres as heretofore. The change has been made to give a

Digitized by Google

firmer seat to the sleeper. The additional length will increase the weight by some 12½ per cent.

Cost of Growing Corn.—The report of the Commission appointed in 1888 by an order of the Minister of Agriculture to inquire into the methods of corn-growing, and to ascertain the average cost in each of the three principal corn-producing districts of Germany, has recently been published. We learn from this report that the general average is, per ton, as follows:—For wheat, 170s. 7d.; for rye, 151s. 10d.; and for oats, 135s. 5d. The extremes were:—148s. and 180s. for wheat; 141s. and 170s. for rye; and 130s. and 141s. for oats.

LILLE, 31st December, 1889.

Textile Manufactures.—The year ends in favourable circumstances for the linen trade of Armentières. In spite of the interruption of business by the Christmas holidays, the last week has been a period of considerable activity. The turnover is greatly above the average for this season, and augurs well for the business of the new year. The tone of the market is in consequence hopeful and firm. This week will, in the ordinary course of things, be given to the New Year festivities and stock-taking. The Roubaix woollen market has continued active down to the last hours of the year, closing to-day with fair prospects.

Protection for the Linen Industry.—At the annual general meeting of the *Comité linier* of the North of France, held here a few days ago, under the presidency of M. Ed. Faucheur, it was resolved to protest against the renewal of the treaties of commerce, and to set on foot an organised agitation "for the adoption of an economical system conformable to the interests of French industry." This means a vigorous attempt to influence the Government in favour of protection for the linen industry.

AMSTERDAM, 30th December, 1889.

The New Factory and Workshops Legislation.—The new Act, which comes into operation on New Year's Day, is the most important statute upon the subject yet enacted in the Netherlands. It contains numerous exceptions, and work in the following establishments is expressly excluded from its provisions: Restaurants and eating-houses, apothecaries, &c., also craft of every description, although even in all these cases it will be illegal to employ children under twelve years of age, except where skippers have their own children or apprentices with them. Labour in the fields, in orchards and market gardens, in forests and upon peat bogs, is likewise excluded from the stipulations of the Act. In the main it provides that, on and after January 1st, 1890, no child under twelve years of age shall be allowed to work in any factory or workshop scheduled in the Act. In shops, however, children under twelve may perform house duties—such as cleaning, going on errands, &c.—duties that have no connection with ordinary labour in factories or workshops. Young persons between twelve and sixteen years of age, also women, must not commence work in an factory or workshop before 5 a.m., nor labour after 7 p.m. Continual day labour may not exceed eleven hours, and in any case one hour's rest must be given between the hours of 11 and 3. Sunday labour is henceforth forbidden, except in special cases and with Jews, but these must give a holiday on Saturday if their employés work on Sunday. For printing-offices and lithographic establishments exceptional stipulations are made. In newspaper offices boys between fourteen and sixteen years of age may remain at work until 6 a.m. on Sunday, provided they are only employed at printing and folding, and have not worked more than eleven hours in the preceding twenty-four hours. Such boys, under similar circumstances, may work on week-days until 10 at night. In lithographic establishments, lads under sixteen may work until 8 p.m., at "chromos" only, between April and October, but then they must not commence work before 7 a.m. In smelting works boys under sixteen may work until 8 p.m., but only up to July 1st. In fish curing establishments, boys between fourteen and sixteen, and young women above fourteen years of age, may work until 10 p.m. from May to November, if such work be necessary to preserve human food. In the workshops of milliners, dressmakers, &c., girls above fourteen and women may be kept at work until 8 p.m., provided their labour did not commence before 8 a.m. the same day. In bakeries and pastrycook shops, boys between the ages of fourteen and sixteen may commence work at 2 a.m. There are numerous other clauses of a similar nature. In all these exceptional cases, no consecutive labour beyond five hours is allowed without a rest of at least half an hour, whilst the aggregate of working hours in a whole day (twenty-four hours) must not exceed eleven. Employers having in their employ young persons under sixteen years of age must provide themselves with cards from the local authorities, upon which they have to enter the names, years of birth, and all further particulars of these young persons, such cards to be returned to the local authorities within forty-eight hours after the young persons have left the employers' service. The latter shall also cause to be made up a list of all young persons and women in their employ, such list to be verified and certified by the local authorities. These registers should contain not only the persons' names, &c., but also their hours of labour and rest, in full. The penalties are fines and imprisonment. Among the other stipulations in the Act the following have to be noted:—No woman is allowed to work within four weeks of and after her confinement. Rest should not take place in the workshops or labour-rooms themselves, as, in that case, it would not be considered as "rest" within the meaning of the Act. An exception is only made for houses where the work-room is also the family-room. Accidents to the employés must be notified by the employers within forty-eight hours to the local authorities, unless they be of so slight a nature that the workman concerned can resume his duties almost immediately.

COPENHAGEN, 28th December, 1889.

Oiling the Waves.—There can be no doubt that the use of oil for the safety of vessels in stormy weather is becoming more general. A Norwegian engineer has recently drawn attention to the important point of selecting the most suitable oil. A fat, heavy, animal oil, such as train oil, whale oil, &c., is decidedly the best, but as these oils in cold weather become thick, and partly lose their ability to spread, it is advisable to add a thinner mineral oil. Vegetable oils have also proved serviceable. Mineral oils, especially refined ones, are the least effective. Crude petroleum can be used in case of need, but refined petroleum is hardly any good at all.

Telephones in Sweden.—From recent statistics, collected by the Stockholm General Telephone Company, it appears that the company on December 1st, 1888, had 4,493 telephones fixed in Stockholm, which number has increased to 5,172 telephones on December 20th, 1889. In addition to these there are over 300 telephones in Bollnäs and Söderhaum, and about 150 in Jönköping. The Stockholm General Telephone Company, which has left its rival, the Bell Telephone Company, a long way behind, has probably the most perfect telephonic installation in the world.

Textile Industries.—Both in Sweden and Norway, as well as in Denmark, the textile industry appears to be steadily extending. Several large manufactories have recently been started, and a new addition is the Hjelmeland wool spinning mills in Norway, which have been bought by a limited company, and will be transformed into a first-class mill, with machinery, &c.

Reclamation of Land.—The Hjälmaren and Koismarens reclamation undertaking in Sweden is a very large affair, and seems to have been so far attended with satisfactory results. At these reclamation works 14,800 hectares of arable land have been laid dry during the year 1877-1888, at a cost of 3,902,523kr., or about £215,000. Another beneficial result of this work is the facilities it has produced in the means of communication by necessitating dredging and deepening works. During the year 1889 a further link in the waterway has been completed—viz., from Hjälmaren through Hyndevad Sound, past the Nordön, *viâ* Tondlaviken to Hyndevad. Another canal, 5,000 metres long, in the direction of Koismaredalen, is about to be taken in hand, and can apparently, at a small cost, be continued through the Koismare lakes.

MADRID, 30th December, 1889.

Manganese Ores in the North of Spain.—Some four or five years ago I visited the district of Muñas, in Asturias, where the existence of good manganese ore was well known. The workings were in such a state that nothing positive could be assured respecting the importance of the manganese. The samples I took were analysed by Mr. de Pourcel, and he found them good and free from phosphorus, but, whilst I consider the existence of manganese ore proper more or less doubtful, I think there is very little doubt that iron ores of a high yield in manganese are to be met in abundance, and that they can be worked at a good profit.

Commercial Treaties.—The Commission appointed to inquire into the results of the existing treaties, and advise about what is to be done with respect to them in 1892, has now circulated the interrogatory. Opinions are very much divided in Spain on every point connected with the matter, and it is most difficult to say what will be the final decision.

Marble Quarries.—The marble quarries of Fuente Heridos, on the railway from Zafra to Huelva, are now actively working on orders for some of the large and luxurious buildings that are being erected in Madrid. The quality is splendid, and the orders would be still larger if they could be attended to without unreasonable delay.

Electric Light Failure.—A few nights ago the best private installation of electric light in Madrid, that of the Royal Theatre, failed when about two-thirds of the performance had passed. The public were warned that the theatre would be in darkness within a few minutes, and they were invited to leave the place, which they did. The cause of the mishap was an escape of steam in the large main going from the boiler house to the engine room. It is a new proof of the necessity of using accumulators.

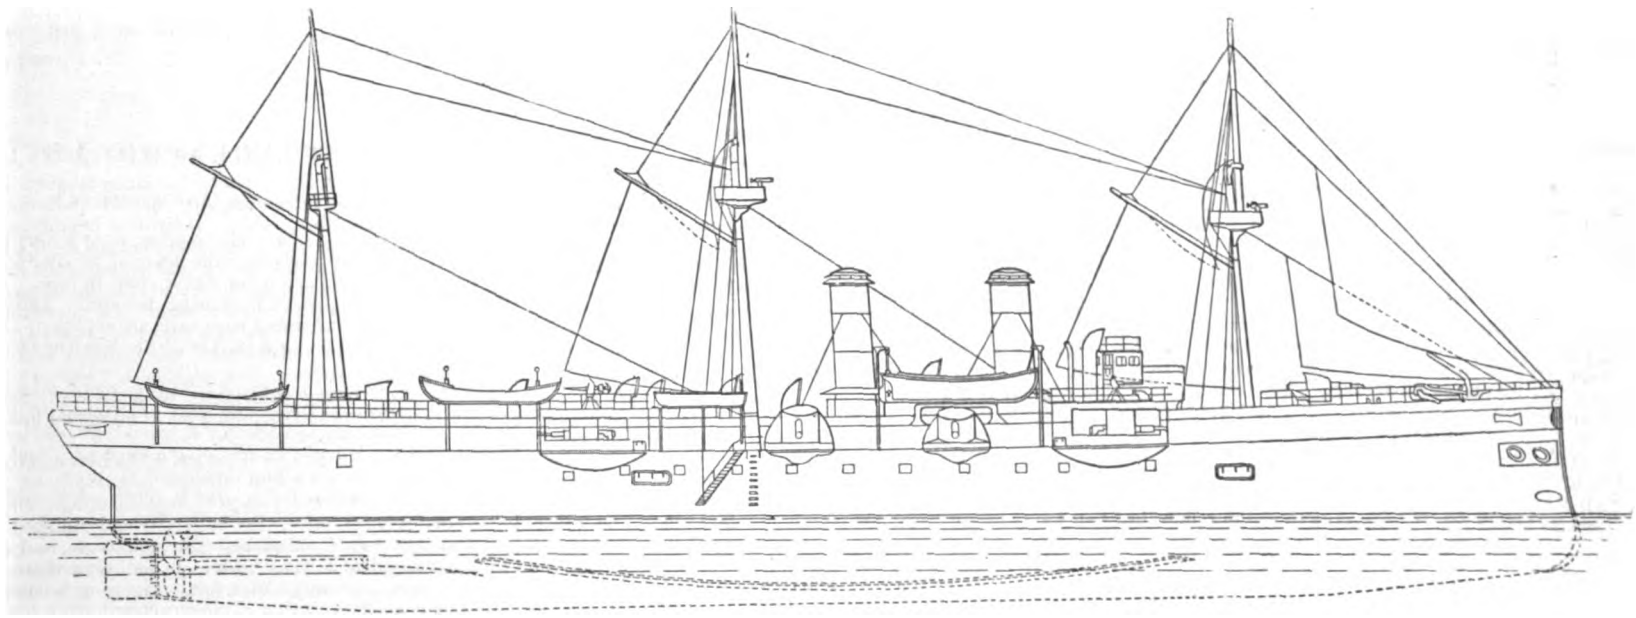
Linares to Almeria Railway.—The Company holding this concession tried to place a large amount of debentures, to be paid within a short time. The public have evidently thought the proceeding unusual, and the demand for debentures has been exceedingly small.

Steel Manufacture in the South of Spain.—Spain, famous of yore for its Toledo blades, is destined to become a great steel producing country. Not only in the north, with its famous stores of hematite iron, but in the south also, with its rich deposit of magnetic iron ore, is steel now being manufactured. The old-established iron works at Heredia, on the shores of the Mediterranean Sea, has quite recently been partly converted into a steel plant for producing steel on the open-hearth process. The plant embodies some of the latest improvements of Mr. James Noble, of Middlesbrough and formerly of Consett, and of Mr. B. H. Thwaite, of Liverpool. The plant has been successfully put in operation by Mr. B. D. Healey, C.E. The plant, as designed by Messrs. Noble & Thwaite, was supplied by Messrs. Neville & Co., engineers, Oriel Chambers, Liverpool, Barcelona, and Madrid. The casting arrangement is on the system introduced by Mr. Turner, of Birmingham.

NEW YORK, 20th December, 1889.

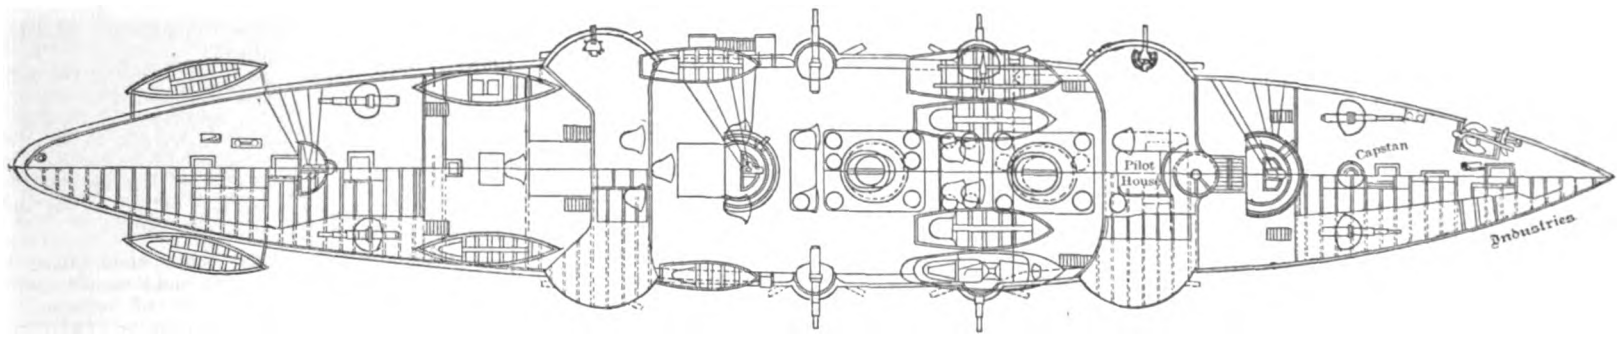
The Coal Market.—There is little change in the anthracite trade. Prices are firm at old quotations, but some concessions are given by individual operators. The demand for furnace and steam sizes continues quite heavy. There is little coal at tide water, and owing to the increase in the iron business newly mined coal is being taken by the furnaces as fast as it can be delivered. In domestic sizes the warm weather of the last few days has caused a decided falling off in orders, and the trade will be likely to continue dull until cold weather sets in in earnest. The bituminous trade is dull, owing principally to a lack of cars for delivery. Operators have quite a lot of orders on hand, but no coal to complete them with.

The Iron and Steel Market.—The iron market continues active, with a slight advance in some lines. Anything like a moderate pressure to place orders would be sure to advance prices for both pig and finished iron. Eastern dealers are conservative in their trade, and are in no hurry to advance prices, while in the West there seems to be a strong upward movement. Pig iron is unsettled, and prices are firm, with a decided upward tendency. Inquiries are for much larger quantities than sellers are willing to offer. Consumption is without doubt the heaviest on record, and production is greater than ever before, and constantly increasing. Quite a large amount of this is taking the place of the material that has heretofore been imported. The scarcity of good ores, and the high prices at which they are held, are other factors tending to raise prices. Prices are about the same as last week, but the best grades are a little higher than a week ago. There is little change in manufactured iron. Bars are steady and in good demand. Mills are full of work, and there are some large plate orders that seem to be hard to place. The outlook is considered to be of the most promising character, with plenty of business and probably somewhat higher prices in the near future. The demand for steel rails is fair, with prices firmly maintained at $35 per ton at mill, with every prospect of higher rates before long. Steel in other forms is in good demand, and the mills are crowded with work.



The Metal Markets.—A large quantity of copper has been sold during the past week at prices ranging as high as 14¼c. for Lake. The market has fallen off somewhat towards the end of the week, and quotations are now 13·90c. to 14c. per lb. for December delivery and 12c. to 12¼c. for casting brands. A moderate amount of business is doing in tin at gradually falling prices. Spot is selling at from 21c. to 21·10c., and March delivery at 21·10c. to 21·20c. per lb. There has been little doing in plates, and prices are unchanged. The lead market is quiet; sales have been light at about 3·85c. per lb. The demand for spelter is increasing, the market closing at 5·35c. per lb. Antimony is in active demand, with prices ruling higher.

Telephone *versus* Electric Cars.—Complaint has been filed against the Eau Clair Street Railway Company and the Sprague Motor Company by the attorneys for the Wisconsin Telephone Company, stating that the operation of the electric street railway system has destroyed the utility of the telephone system, and that the street railway is of a dangerous character and without proper safeguards for the protection of the public. It prays for an injunction restraining the Street Railway Company from operating its railway by electricity until its wires are insulated or return wires put in. The trouble is said to arise from the fact that there is an almost constant buzzing and roaring in the telephone caused by induction.



Cotton.—The December cotton report of the Department of Agriculture relates to prices on plantations. Correspondents report late maturity. In the northern belt early frost arrested the development of the bolls and seriously reduced the harvest. In the larger and more southern areas, while killing frosts were reported in some localities, in October losses were neither severe nor general from this cause. In the most productive portion of the belt there was little frost until the last week of November. The season has, therefore, been a long one, counterbalancing the late development of the plant. The top crop is fairly abundant, and general mention is made in the more southern districts of a burden of bolls yet unopened which may open with a continuance of mild weather. Weather for picking has been favourable, and the lint is generally bright and clean, though not everywhere of full length. Prices are little better than those of last December, plantation prices varying from 8·3c. to 8·7c. per pound. The cotton spinners of Fall River are making another attempt to form a federation of cotton operatives, and have sent invitations to operatives in cotton centres in New England and the Atlantic States to be represented at a convention to be held on the 15th prox. Attempts have been made before this one to form a federation, but unsuccessfully, as operatives in other cities have not been so well organised as in Fall River. In view of the eight hour agitation it has been decided to make another attempt.

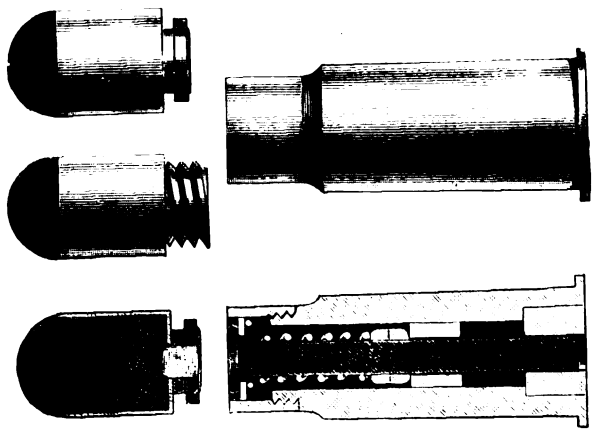
THE UNITED STATES CRUISER "SAN FRANCISCO."



ELEVATION.

PLAN OF POOP DECK.

THE MULLINEUX CARTRIDGE.

We are indebted to the *Admiralty and Horseguards Gazette* for the following account of this cartridge. Our contemporary remarks that what promises to be a most useful invention for the Service, and also a source of amusement to all lovers of the rifle, has just been produced by Mr. M. Mullineux in the shape of a substitute for the Morris tube. It consists of a gun-metal or

steel cartridge case similar in shape to the Martini-Henry cartridge. The case can be unscrewed into three sections. At the end of the case is affixed a small section containing a charge of powder and a bullet, together with a percussion cup fitted in its base in a manner similar to the ordinary cartridge. The remainder of the case contains an elongated striker, which acts on the percussion cap when the main spring of the rifle is released. The bullet used, being of the correct diameter, takes the groove of the rifling. The section containing the bullet and charge of powder is but ¾in. in length, so that any number can be conveniently carried in the pocket, together with the remainder of the case containing the striker. After firing, all that is necessary is to remove the end section which contained the powder and bullet and replace it by a fresh one. The charge of powder is regulated by the distance at which it is desired to fire, and it is possible to use these cartridges at a distance of only ten yards. Although the case is similar in shape to the Martini-Henry cartridge, it can be supplied to fit any rifle, and the sights attached to any rifle can be used with it with accuracy. Being so small, the cartridge has, of course, no effect on the weight of the barrel, and is, in fact, practically the same as the ordinary cartridge except as regards the length and weight of the bullet and the strength of the charge. Sections containing any charge suitable to the distance required can be obtained, and it has been found that the splash from the bullet on impact is in no way dangerous. The cartridges are made in a thoroughly durable manner, and there is no point at which any amount of the roughest wear and tear would be likely to damage them. As regards cost, it is stated that they compare most favourably with other similar inventions. The cartridges are now loaded with smokeless powder, and the result has proved perfectly satisfactory. The rifle will stand any number of rounds being fired without cleaning out.

THE UNITED STATES CRUISER "SAN FRANCISCO."

The "San Francisco" was successfully launched from the Union Iron Works in San Francisco on October 26th last. This ship is the second one built for the Government in the same yard, the "Charleston" having been the first. The contract was let in July, 1887, the construction of the vessel having been authorised by the Act of March in that year. This ship and the "Philadelphia," which is building at Cramp's Yard in Philadelphia, are sister ships, and the contracts were let at the same time, the price for the "Philadelphia" being 1,350,000 dols., and for the "San Francisco" 1,428,000 dols. This ship is a twin-screw cruiser 328ft. long over all, 310ft. on water line, 49½ft. in breadth, 31ft. 6in. depth, 18ft. mean draught, and her displacement, when completed, will be about 4,100 tons. The vessel is not armoured, but carries a heavy protective deck just above the water line, and the machinery is further protected by the arrangement of the coal bunkers. The engines are of triple expansion type, with cylinders 42in., 60in., and 94in. in diameter, and 42in. stroke. The boilers, 15ft. diameter, will carry a working pressure of 135lb. per square inch. The two screws are three-bladed and 14½ft. in diameter. The engines are expected to develop 7,500 h.p. under natural draught, and 9,000 h.p. under forced draught, and the maximum speed is to be 19 knots an hour. The armament is to consist of twelve 6in. guns, with a secondary battery of small rapid-fire and machine guns. We give above two illustrations showing respectively a side elevation and deck plan of this ship. The "San Francisco," the "Philadelphia," and the "Newark" are the largest cruisers yet built for the United States Navy, but will be exceeded in weight, fighting power, and strength of armour by the "Maine," the "Texas," and the new battle-ship for which designs are now being prepared in the Navy Department. We are indebted to our American contemporary, the *Railroad and Engineering Journal*, for the above description of this vessel.

SHIPBUILDING NOTES.

On the 21st ult. Messrs. Richardson, Duck, & Co. launched from their building yard, at South Stockton, a three-masted iron sailing ship of the following dimensions: Length, 315ft.; breadth, 42ft.; depth of hold, 24ft. 7in.; gross tonnage, about 2,400 tons. This vessel has been built to the order of Messrs. W. H. Ross & Co. She has a full poop with accommodation for passengers, captain, and officers, and a deck-house amidships for crew, petty officers, and galley. She has been built under the superintendence of Captain Hamilton, and will be commanded by Captain Steel. As the vessel was leaving the ways she was christened the "Scottish Moors."

On the 21st ult. Messrs. Harland & Wolff, Limited, Belfast, launched the large steel screw steamer "Nizam," for the Asiatic Steam Navigation Company. This vessel is a sister ship of the "Nawab" and "Nadir," also built in this yard for the said company during the past year. Her

Digitized by Google

dimensions are: Length, 345ft.; breadth, 42ft.; gross tonnage, 2,970 tons. The boilers and engines are being built by the same firm, and the vessel is expected to be ready for sea in a few weeks.

Notices of Meetings.

THIS WEEK.

GEOLOGISTS' ASSOCIATION.—Friday, January 3rd. Papers to be read: "On the Fossil Fishes of the English Lower Oolites" (illustrated by specimens from the collection of Thos. Jesson, F.G.S.), by A. Smith Woodward, F.G.S., &c.; "A Short Account of the Excursion to the Volcanic Regions of Southern Italy" (illustrated by photographic views), by H. J. Johnston Lavis, M.D., F.G.S., &c.

NEXT WEEK.

ROYAL INSTITUTION.—Saturday, January 4th; Tuesday, January 7th; and Thursday, January 9th, 3 p.m. Christmas Lectures on "Electricity" (adapted to a Juvenile Auditory), by Professor A. W. Rücker.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, January 6th. Mr. C. T. Kingzett, "Peroxide of Hydrogen: Its Preservation and Commercial Uses"; Mr. Lovibond, "An Analytical Tintometer."

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—Wednesday, January 8th, 7 p.m. Annual General Meeting.

PRICES CURRENT, 1st JANUARY, 1890.

Quotations at per ton, unless otherwise specified.

Market firm, and advancing.

Messrs. E. S. Ferguson & Co., of Cardiff, report as follows:—Business generally wears a holiday aspect, and there is little new to report this week. The tendency in the steam coal market seems still in the upward direction, and it is with the utmost difficulty that shipowners can get their vessels steamed. The activity in the iron and steel trades is still unabated, but the supply of coke seems far from adequate. Great apprehension is being evinced by consumers as to their supplies of Spanish ores, more particularly those from Bilbao, which are urgently required. As has been anticipated in these columns for the past month or two, it is now reported on the best authority that two or three firms in Bilbao have declared their inability to carry out the contracts made by them at the lower figures, so that to make good these quantities importers on this side have had again to cover themselves at considerably higher prices.

Messrs. Carrick & Brocklbank, Manchester, report as follows:—

COPPER: From the 24th to the 30th ult. there was no London market, owing to Christmas holidays. It is reported that about 1,250 tons of Chili bars changed hands on the 24th, speculatively, in view of a firmer market early this year. On the reopening of the market on Monday Chili bars were firm at the rates ruling on the 24th, viz.—£50 to £50 7s. 6d. cash—and to-day's quotations are the same. Manufactured is still firm at £66 to £69 sheets and bottoms.

TIN: Slightly firmer in tone, with moderate business doing.

LEAD remains unaltered in price.

SPELTER: Still very scarce and slightly dearer, with every prospect of higher rates after the turn of the year.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—There is very little news to report, the holidays having made matters quiet. Caustic soda continues firm, and bleaching powder is showing a hardening tendency. Soda ash and soda crystals unchanged. Sulphate of copper is more easily procurable, but price is steady, and the inquiry for green copperas for export has slackened. Yellow prussiate is strong at the advance. Acetates of lime have moved up, and will, probably, advance further. Very large sales of grey have been made from America for 1890, and stocks of all qualities are now firmly held. Carbolic acids continue very dull; other tar products steady.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, Jan. 2.—*Iron.*—The market here is very firm, at 160s. for bars and joists, but the demand is languid. The provincial markets are quiet but strong in tone. Wire in the Haute Marne is in increasing demand. Annealed is quoted 192s. a ton. Steel wire nails are selling at 216s. for the No. 18. The pig iron market of the Meurthe-et-Moselle is very firm.

Metals.—There is not much life in the metal markets this week. Copper remains practically unchanged in price, at £53 for Chili bars and £58 for English best selected. Tin has given way a little, Banca being quoted £107 and Straits £102. Lead is quiet and unaltered in price, at £14 8s. Havre. The market for spelter is more active, and prices have risen to £25 15s. for Silesian brands at Paris.

BERLIN, Jan. 2.—*Bourse.*—The market is fairly active for industrial securities. Shares in colliery companies and in iron and steel works have further risen in price in consequence of the strike of colliers in Belgium, an immediate effect of which must be to restrict Belgian competition.

BRESLAU, Jan. 2.—*Coal.*—The scarcity of coal is keenly felt. Many manufacturing works are running short time, and even domestic consumers complain of a want of fuel. Prices are higher to-day by 1s. a ton. Merchants are buying up all in the market. Colliers are receiving better wages and are more contented.

Iron.—Though we are in the midst of the holiday and stock-taking season, there is considerable activity in the market for iron. Pig iron continues to be briskly dealt in. Forge pig is quoted 80s.; foundry, 85s. to 90s. Magnetic iron ore is being largely imported from Sweden. Business is active in finished iron and steel. Bars are officially quoted 190s. per ton at works, but it is difficult to buy under 200s. Boiler plates are 240s., and sheets 240s.

DÜSSELDORF, Jan. 2.—*Iron.*—Stock-taking has kep buyers out of the market to some extent; nevertheless there is a fairly strong current of business. Ordinary spiegel pig has advanced to 102s. in the official quotations. Forge pig is scarce and very firm in price. The same may be said of foundry pig. The amount of business being done in finished iron and steel is much above the average for the season. Tone very firm.

BRUSSELS, Jan 2.—*Bourse.*—The prices of shares in colliery companies are again bounding upward, but other industrial securities, especially shares in iron and steel works, are flat. Glass works, which will suffer from the higher cost of coal, are less favourably regarded as an investment.

CHARLEROI, Jan. 2.—*Coal.*—The number of colliers out on strike is estimated at 15,000. Many works are stopped for want of fuel. In the present state of things it is impossible to quote prices. Several large consumers have sent agents to England to buy coal. The French colliery owners have agents here briskly booking orders for prompt delivery.

Iron.—The iron market is greatly disturbed by the coal-miners' strike. Brisk buying is taking place in some classes of iron, notably plates, in anticipation of higher prices. The market is, however, not exceptionally firm. Longwy pig is being sold here at 69s.

LILLE, Jan. 2.—*Flax and Yarns.*—The flax and yarn market is but thinly attended as usual at this season. But though business is quiet, prices are firmly maintained. Russian flax is a little more inquired after. Stocks of tows are low. Buyers of yarns are not disposed to operate at this stock-taking period. There is, however, a good demand for jute yarns.

OMNIBUS LICENCES.—It is stated that the Board of Inland Revenue, giving effect to the decision in the Court of Queen's Bench, have now ordered the repayment of all licences paid by omnibus proprietors and tramway companies, and that a hackney carriage licence of 15s. be issued instead. This is a return of 27s. on each licence, and the total repayment by the Board of Inland Revenue will be about £150,000.

THE LONDON CHAMBER OF COMMERCE.—The following circular will shortly be issued by the Electrical Section of the Chamber to the members, on the question of "Blocking Orders":—"The attention of the Electrical Section has been called to the fact that many of the notices which have been given by the local authorities of their intention to apply for provisional orders have been given with a view of blocking the extension of electric lighting, owing to gas interests or other causes. The matter will be brought forward at the next meeting on the 28th inst., and it is hoped that you will communicate to Mr. Trotter, the correspondent, any corroborative evidence of such action as you are able to give, together with as many details as possible."

Digitized by Google

HOME INDUSTRIES.

LONDON 2ND JANUARY, 1890.

THE MONEY MARKET.—The year closed rather sensationally in the Money Market, the Bank Directors meeting hurriedly on Monday morning to raise the Bank Rate to 6 per cent. The Bank Return had been very unfavourable, and with an increasing note circulation, due to the expansion of trade, and a continuous though gradual drain of gold from this country, it behoved the Bank to take steps to preserve its stock of gold from further diminution. Curiously enough, the raising of the Bank Rate did not have the usual effect on speculative business on the Stock Exchange, though no doubt the dearness of money must tend to check speculation. Still, a year of high values and good business closed with prices very strong in almost every department. To a certain extent this was not a fair criterion of the state of the market, for with the public quite out of the markets at this season, prices may be put up quite apart from dealings. No doubt the jobbers, wishing to end a good year well, put quotations up all round, a circumstance which might lead the public early into the market again in the hope of repeating the fortunate strokes made by speculators for the rise in 1889.

COMPANIES.—The following companies have been registered since our last report:—The Astracana Sailing Ship Co., Ld., with a capital of £14,700; Witty & Wyatt, Ld., with a capital of £30,000, to carry on the manufacture of asbestos goods; The Gemming & Mining Company of Ceylon, Ld., with a capital of £100,000: Southampton Naval Works, Ld., with a capital of £274,000, to carry on the business of shipbuilders belonging to Messrs. Oswald Mordaunt & Co.; The Audenshaw Paint and Colour Co., Ld.; The Corona Hill (Australia) Silver Mining Co., Ld., with a capital of £150,000.

WOOL.—Messrs. Charles Balme & Co. report as follows:—"The more prosperous character of the period covered by the past twelve months is reflected in the statistics embodying the year's operations in wool, a steady and gradual, though, at times, somewhat halting, movement in the direction of expansion and improvement having marked the progress of the industry upon which our article depends. To this result several circumstances have contributed, and among them we may especially mention (1) increased confidence in regard to the maintenance of European peace; (2) more general and profitable employment among the working classes, and a consequently enlarged purchasing power on the part of the great mass of consumers; and (3) a comparatively moderate increase in the supplies of the raw material. A comparison of the prices ruling at the close of 1888 and 1889 establishes roughly an advance in merino produce ranging from 8 to as much as 15 per cent. in particular descriptions, and in crossbred staple of the coarser types of about 10 per cent., in favour of the later period, the bale average of the year being the highest recorded since 1884."

HEMP.—In Baltic hemp and yarns there is nothing doing for spot, and quotations are unaltered. Last week's arrival business has been quite small, but the prices are firm. The Italian markets are exceedingly firm, and prices have advanced slightly. The quantity of Italian hemp in producers' hands is very small. Nothing has been done in Manilla hemp.

SOCIETY OF ARTS.—The following arrangements have been made for the ordinary meetings of the Society between Christmas and Easter. These meetings are held on Wednesday evenings at eight o'clock:—January 15th, adjourned discussion on Sir Robert Rawlinson's paper on "London Sewage;" January 22nd, R. Brudenell Carter, F.R.C.S., Vice-President of the Society, "Vision-testing for Practical Purposes;" January 29th, Gilbert Redgrave, "The Utilisation of Blast-furnace Slag;" February 5th, Arthur Paget, "High-speed Knitting and Weaving without Weft;" February 12th, George Findlay, General Manager London and North-Western Railway, "Modern Improvements in Facilities for Railway Travelling." The dates for the following papers have not yet been fixed:—Sir Douglas Galton, K.C.B., D.C.L., F.R.S, Vice-President of the Society, "The Chemin de Fer Glissant, or Sliding Railway;" G. N. Hooper, "Carriage Building and Street Traffic in England and France;" J. S. Keltie, "Commercial Geography;" J. Tripplin, "Recent Progress in British Watch and Clock Making;" Arthur Montefiore, "The English in Florida;" Professor Silvanus Thompson, "The Organisation of Secondary and Technical Education in London."

THE "ELECTRICAL REVIEW."—The *Electrical Review* of New York, one of the leading United States electrical journals, has now taken offices at Bridge House, 181, Queen Victoria Street, London, E.C., where in future all editorial communications, advertisements, or subscriptions are to be addressed to the London editor and manager, Mr. Charles ffrench.

CHANGE OF ADDRESS.—On the 1st inst. Messrs. John Birch & Co., engineers and merchants, removed their head offices from 40, Chapel Street, Liverpool, to 10 and 11, Queen Street Place, London, E.C.

MANCHESTER, 2ND JANUARY, 1889.

THE IRON TRADE.—Although in the engineering trades in Lancashire the remainder of this week is generally observed as a holiday, the market on the last day of the old year was a very strong one. In sympathy with the upward movement in the Scotch and Middlesbrough markets the local makers of pig iron are very firm, and are indisposed to book too much new business, although a good deal is offering. It is expected that the forthcoming quarterly meetings will result in an advance of prices, and makers are naturally reluctant to forestall it. Hematite pigs are dear and scarce, with no great quantity offering. Finished iron bars are also very sparely offered, and prices are firm, £8 10s. per ton being the nominal quotation.

CO-OPERATIVE TELEPHONY.—A meeting was held on the 23rd inst., at which a report of the committee appointed to investigate the chances for the establishment of co-operative telephones was received. The report stated that over 1,300 persons had provisionally agreed to become renters, and recommended the formation of a limited liability company to carry the project into effect. The registered capital of this company is to be £100,000 in the first instance, of which £20,000 to be issued first to establish the Manchester business. The co-operative system is to be applied, no greater dividend than six per cent. being payable, but the establishment of a reserve fund is provided for. A committee was formed to carry the suggestions into effect, and it is expected that some steps will shortly be taken.

THIRLMERE AQUEDUCT.—A somewhat unusual occurrence took place at a special meeting of the Manchester City Council on the 23rd ult., when a report was presented by Mr. G. H. Hill, C.E., relative to the state of the works on No. 4 contract for the aqueduct bringing water from Thirlmere. The engineer reported that the contractor was not making the progress expected or according to the terms of his contract, and that the delay arose from causes within his control. He therefore recommended that the Council should exercise their reserved rights and terminate the contract. This the Council unanimously agreed to do, and directed steps to be taken to seize all the plant at present on the works. The contractor has since obtained an injunction to restrain such seizure.

HYDRAULIC POWER MAINS.—A private Bill is to be promoted during the forthcoming session of Parliament to authorise the carrying out of the necessary works to provide a high pressure water supply in a similar manner to that pursued in London and Liverpool. This project was mooted about three years ago, but owing to the opposition of the City Council was then dropped. It is intended, however, to proceed with it this year. The engineers to the promoters are Mr. Corbett Woodall, C.E., of London, and Mr. C. Hopkinson, C.E., of Manchester.

THE LINEN AND JUTE TRADES.—Although the present is a broken week there are signs that the linen trade is about to enter on a period of much greater activity. Stocks are believed to be low in many departments, and, to judge from the contracts entered into by buyers, a large consumption is looked forward to. Prompt deliveries are being insisted on. There is not much to report regarding the current demand, which is, of course, slow, owing to the interruption to business caused by the holidays. Regarding prices, future prospects are not unsatisfactory. It is safe to say that the rates which for some time manufacturers have been accepting scarcely made it worth while to keep their looms running, and, looking at the wretched nature of the Irish flax crop, and the consequent scarcity and dearness of prime qualities, fine goods promise to maintain their present firmness. Linen thread houses would certainly advance their lists again were it not for the fear of driving customers to the use of higher class materials in the shape of silk threads, or lower class ones such as cottons. As it is, they are perforce compelled to be content with the prices established in January of last year. Jute goods are in average demand, and the new fancy varieties promise well. The detailed circulars with reference to the carpet syndicate will, it is expected, be in the hands of those interested on the 10th inst.

GLASGOW, 2ND JANUARY, 1890.

SHIPBUILDING.—Messrs. Holt, of Liverpool, have placed an order with Messrs. Scott & Co., Greenock, for two large steamers. Clyde builders continue to refuse orders, owing to the impossibility of guaranteeing anything like prompt execution of the work. The slipways are nearly all occupied. Messrs. Russell & Co., Port Glasgow, have sold two steel four-masted barques, now building. The vessels are each 2,500 tons, and are sold at about £10 10s. per ton gross register.

NEW BUILDINGS IN GLASGOW.—A proposal has just been placed before the Town Council by the Lord Provost, to the effect that the surplus from the Exhibition of last year, amounting to upwards of £50,000, be supplemented by a public subscription of £150,000, and the sum of £200,000 devoted to the erection of an Art Gallery, on or near the site of the Machinery Section of the Exhibition.

FORTH BRIDGE.—It is announced that the Forth Bridge is to be opened on the 4th March by the Prince of Wales. The plant which has been used in the erection of the bridge has now been sold off, and the staff is rapidly being dispersed. There is no doubt that the permanent way on the bridge, and even the approach railways, will be completed well within the two months that will elapse before the official opening.

PIG IRON.—The pig iron market remained strong till the close of the year, and at midday on Tuesday, when the market ceased for the year, the prices were 64s. for Scotch iron and 62s. 6d. for Middlesbrough. It is reported that the considerable stocks, amounting to about 30,000 tons, of Cleveland iron which had accumulated in Glasgow have been entirely cleared off, and it is suspected that stocks in makers' hands have been reduced to a mere fraction of what they were at the beginning of the year. On Monday the Scottish Pig Iron Trade Association met and decided to boycott the London Metal Exchange, by binding its members to buy and sell and settle only in Glasgow. The production of pig iron during the past year has been 998,928 tons, according to Messrs. Bost & Turner's statistical report, with which we have just been favoured, there being a decrease on the production of the previous year of 28,846 tons. The number of furnaces in blast in both years was the same. The average production per furnace per week has fallen off from 3 per cent., or from 236 tons to 228 tons. The consumption in foundries has increased 48,000 tons, and that in malleable works 125,000 tons. The exports, foreign, have increased 6,000 tons; coastwise, 12,000; and by rail, 4,300. The stocks in Connal's stores have decreased 87,000 tons, and at makers' works have decreased to the startling amount of 121,000 tons, or from 213,000 to 92,000 tons, a total decrease of 208,000 tons. The stock in Connal's stores, at the close of the year, is 4,000 tons less than it was in the end of 1888. Messrs. Bost & Turner give the minimum price of pig iron at 42s. on the 3rd January, and the maximum price 64s. 10d. on the 18th November. They anticipate a very busy year in the pig iron trade, although they point out that, owing to the difficulty of obtaining coal, coke, and ore, and the advance of wages, they do not see much chance of an increase of production. Wages, they say, have been 5s. per day over the year, as against 4s. 3d. last year.

THE YEAR'S TRADE IN GLASGOW.—Everywhere in the manufacturing industries of Glasgow the course of trade has, during the year, been extremely prosperous. Shipbuilding yards and engineering works have been more prosperous than in any year since 1882, and steel works have been busier than ever before. Freights have been good, and thus shipbuilding has been encouraged. The coal trade has been somewhat unsettled, the strikes in Westphalia having affected the shipping trade to a considerable extent. Among the notable incidents of the year have been the strike of dock labourers on the Clyde, strikes of riveters in Glasgow and Greenock, advances in colliers' wages, and advances in wages almost all round. The expansion of the trade of the port has been so considerable as to hasten the Clyde Trustees in the construction of the new docks at Cessnock Park, Govan, and these are now being rapidly pushed forward, the north wall being now completed. Among the notable items in the import trade is the increase in Indian corn. Imports of this article, which stood steadily for some years at about half a million quarters, reached, last year, 850,000 quarters. The most important increase in export items is that in coal, which exhibits an increase over last year of three-quarters of a million tons, or 14 per cent. Among striking import statistics is the increase in the trade in American rosin and tar. The latter seems to be replacing almost altogether Archangel tar, which formerly had a very large market in Glasgow. Boiler-making and general engineering have been steadily prosperous all the year. Large orders for the colonies and for the United States have been in course of execution during the past few months, while home engineering enterprises have also been supplied by Glasgow firms. The shield for the Hudson Tunnel, as well as the bridges for the Manchester Ship Canal and the Tower Bridge, have kept Messrs. Wm. Arrol & Co. busy since the practical completion of the Forth Bridge. The Manchester Ship Canal is being supplied with a powerful dredger by Messrs. Wm. Simons & Co. The tunnel under the Clyde, which a company under the inspiration of Messrs. Baird & Co. has been formed to construct, may be expected to be among the engineering features of next year, as will also the construction of the tunnel under Argyll Street to convey the Caledonian branch railway from East to West Glasgow. The excessive activity in steel manufacture has had naturally an important effect upon the fire-brick trade. Prices have nearly doubled, and at Glenboig, the works of the Glenboig Company and those of Mr. Peter Hurll, newly established, are both very busy.

(From our own Correspondents.)

LIVERPOOL, 1ST JANUARY, 1890.

A LARGE CONSIGNMENT OF BULLION.—One of the largest consignments of silver ever landed in this country arrived in the Cunard Steamer "Umbria" last Sunday. It consisted of 873 bars of solid silver, weighing 24 tons, and valued at £178,000, and was conveyed by special train to London. One half this amount was consigned by Messrs. Zimmermann & Foshay, bankers, Wall Street, New York.

THE MASTER CARTERS.—On account of the great increase and extension of the dock system north and south, and of the revival in trade, the master carters consider they do not receive adequate pay for the increased distances and for the frequent long delays. A large meeting was called last week, when it was unanimously resolved, "that it has now become necessary to seek such advances as may enable cart-owners to make a reasonable profit." It is not their intention to strike, but they hope to be able to convince the traders that their claims are just ones. The present rates are based upon those of twenty years ago, when trade was not at its best, and in the interval, trade arrangements have undoubtedly not been to the advantage of the master carter. One hundred years ago, a load was from 8cwt. 4lb. to 19cwt., and a double load between 19cwt. and 30cwt.; no carman was allowed to load more than one cart or barge—each taking in turn; the working hours were seven hours per day in winter and ten hours per day in summer, while the pay was 7s. 6d. per day for a cart and two horses.

LEEDS, 1st January, 1890.

The Iron and Steel Trades.—The year which closed yesterday was one of remarkable commercial prosperity. In the beginning of 1889 a great expansion of local trade was predicted, and the prediction was realised to the full. Throughout the year an immense volume of business was done, and 1890 opens with a very rosy prospect indeed. In the first half of 1889 there was not much improvement in prices, but the next six months saw to a large extent the realisation of the hopes of producers. The great advance in raw materials was followed by a proportionate increase in finished iron and steel, and to find a parallel to the state of things existing on the eve of the late holidays in the iron, steel, and engineering branches of Leeds trade, we have to turn to the memorable years 1870 to 1873. During the year a vast amount of overtime was worked, and in some instances the wages of employés were enhanced. A pleasing feature of the heavy industries in the year was the relations between employers and workmen, only one or two disputes, and those not of a serious nature, arising. As in 1888, so in 1889, the steel trade of the district developed to a considerable extent. In two years the production of steel in Leeds alone shows an increase from 200 tons to about 1,200 tons a week. The largest proportion of the recent increased output of steel is from the Leeds Steel Works, while Messrs. Taylor Brothers, the Monkbridge Iron Company, and the Leeds Forge Company have added considerably to their resources. This development of the steel industry did not lessen the production of the best Yorkshire iron trade, which shared the general prosperity in the year. Nothing but success can be written of the engineering trade. The Christmas holidays now being over, all the forges, foundries, and engineering establishments are again in full operation, and the reports on lal hands are of a most hopeful character. Builders of locomotive and stationary engines are busy on home and foreign orders, the execution of which will take considerable time. There is a large demand for machine tools and general machinery, and makers of textile machinery are well off for orders.

The Coal Trade.—The general revival of trade during the past year was more advantageous to the miners than to the coalowners. The latter did not begin to experience the full benefit of the improvement until three months ago, owing to the higher wages they had to pay and the increased cost of colliery material. With the new year the miners receive an advance of 10 per cent., making 30 per cent. in twelve months. As to the present and future prospects, there is a good demand for coal of all classes, and coalowners who hold locomotive orders experience no little difficulty in meeting the demands. Prices have an upward tendency. An increasing proportion of the West Yorkshire coal is being sent to London and the South, and there is also an extensive export business being done.

SHEFFIELD, 1st January, 1890.

The State of Trade.—There is very little business of any kind being done here this week. At most of the works extensive repairs to machinery and plant have been necessary owing to the heavy strain put upon them during the past year. The "Atlas" Works have restarted their large blast engine, and the blast furnaces are again in working order. The iron and steel moulders have succeeded in obtaining from the manufacturers, as a body, an increase of wages amounting to 2s. per week. This will give ordinary moulders 38s., and machine men 40s., for a week of 54 hours. Trade prospects for the coming year are bright. On all hands there appears to be plenty of employment. Colliery owners will, for the first six months, be placed at a slight disadvantage, the miners' wages being 30 per cent. higher than last year, while some of the coal contracts run for six months longer yet.

DERBY, 1st January, 1890.

The Coal Trade.—The demand for all descriptions of engine coal is considerably in excess of the supply, owing in no small measure to the improved condition of the cotton trade, which diverts large quantities of this class of fuel from our immediate district. The increased requirements for house purposes as the season progresses, together with the general prosperity of the iron trades, also contribute to make supplies scarce, so that prices are advancing by leaps and bounds, a quotation hardly holding good for 24 hours. No wonder, then, that notice has been given to the miners at all the chief collieries in Derbyshire that an increase of 10 per cent. in wages will be given on the first making-up day in January. This is the third 10 per cent. advance granted within the last 15 months, and it has been estimated that the total additional payment in wages in this county alone means an increase at the rate of £312,000 per annum to the men.

The Brewing Industry.—Messrs. Acton & Co., Ld., of Derby, have just declared a 10 per cent. dividend on their ordinary capital, with a bonus of 2s. 6d. per share.—At Burton the maltsters recently organised a strike, which has been perfectly successful, although it was quite unnecessarily attended with violence. Some of the men entered the premises of Messrs. Ind, Coope, & Co., and assaulted Mr. Brown, the manager of the malting department, and his son, who came to the defence of his father.—The brewers' labourers are now to the fore, and demand some increase on what they regard as a scanty wage of 17s. per week.—Works are being erected at Burton to dispose of brewers' and distillers' grains in a more profitable manner than is at present practised. This source of food for cattle can be greatly improved by the Passburg process of drying, which will introduce what is practically a new industry into the town.—A ventilating beer-barrel has been brought out by Mr. Woolrich, which is provided with simple mechanism to release the accumulated carbonic acid gas when it attains a certain pressure. By this means, it is asserted, may be prevented the enormous percentage of returned ales, which, in a notable instance this last season, were so great as to completely swamp the dividend of one company.

BARROW-IN-FURNESS, 1st January, 1890.

Another Advance in Iron and Steel.—At variance altogether with anticipation the hematite pig iron market has evinced considerable improvement during the past week or ten days. The demand for hematite pig iron has been strengthened, and makers are in receipt of numerous inquiries for large parcels for forward delivery. Prices have advanced to 79s. and 80s. per ton for parcels of mixed numbers of Bessemer iron net f.o.b.; and hematite warrants, which last week were at 73s., have advanced rapidly to 78s. 6d., and are still buoyant. There is a slight increase to note in the stocks of iron to the extent of over 1,000 tons. They now represent 380,000 tons, but are over 50,000 tons less than they were in January, 1889. In the steel trade there is much life, and the demand shows great strength from both home and foreign sources. Heavy rails are quoted at £7 per ton, light rails at £7 10s., and colliery sections at £7 15s. per ton. There is a heavy and increasing trade being done in steel shipbuilding material, and the mills are very vigorously employed on heavy contracts, which will require several months to complete.

Shipbuilding and Engineering.—There is a very brisk business in shipbuilding and engineering, and the heavy orders on hand are likely to be supplemented with other important contracts, which will make these industries very brisk during the ensuing year. There is some prospect of large orders for putting triple expansion engines into several well-known steamers, and large orders are pending for the highest class of ocean-going vessels.

MIDDLESBROUGH, 1st January, 1890.

Pig Iron.—The market is quiet. The holidays have had their influence, but of course this is the dead season of the year, when quietness reigns. The market, however, is firm, with the prospect of an increasing business as the season advances. No. 3 G.M.B. is quoted at 61s. 6d. to 62s. for prompt delivery, and 62s. 6d. to 63s. for delivery over the first quarter of the year, which figures indicate the conviction that the favourable run of business will be continued. Cleveland warrants range from 61s. to 61s. 6d.

Shipments of Pig Iron.—The shipments of pig iron for the past week are rather better, but still they are very small comparatively. For the week they amount to 11,621 tons, as against 11,329 tons for the previous week. Up to the 30th ult. they amounted to 40,323 tons, as against 75,007 tons to a similar date the previous month, and 70,682 tons last year. Of course there will be an increase in stocks, the only question being how much.

Finished Iron and Steel.—There is no change in finished iron and steel. Most works take advantage of the holidays to lay off for repairs. Prices are firm, with a tendency to rise, but as yet there is no change except in some special brands, which have advanced from 5s. to 10s. per ton. The exports of finished iron and steel are maintained, and compare favourably with those of a similar period last year.

Coal and Coke.—The holidays have interfered with the output, but the demand continues strong. Prices are firm; indeed, they are a little higher for the time being. Gas coals are at 14s. to 15s.; steam coal, 13s. to 14s. Coke is as scarce as ever, as high as 31s. per ton being asked.

SUNDERLAND, 1st January, 1890.

Shipbuilding.—The returns for the shipbuilding of the year are now complete, and show that there has been greater activity in this industry than in any past years. One hundred and two vessels of 217,345 tons have been launched, as compared with 75 vessels of 142,410 tons in 1888, which exceeded each of the three previous years. The present output has only been approached, as far as tonnage is concerned, by that of 1883, when 128 vessels of 212,313 tons were launched. As in last year, thirteen shipbuilding establishments contributed to the result, Messrs. Jos. L. Thompson & Sons, North Sands, again heading the list with 13 vessels of 30,543 tons, which, however, is a decrease of 3 vessels and 4,578 tons, as compared with 1888, due partially, at least, to irregularity of delivery of material and workmen. Messrs. Short Brothers, Pallion, fall from the second position to the fifth, despite of the fact that they launched an additional steamer and had 2,444 tons larger output, the vacated place being occupied by Mr. James Laing, Deptford, who has turned out 11 vessels of 29,160 tons. Messrs. William Doxford & Sons, Pallion, come next with 10 vessels and 24,150 tons; then the Sunderland Shipbuilding Company, Limited, with 11 vessels of 23,565 tons. Messrs. R. Thompson & Sons, Southwick, occupy the sixth position with 8 vessels of 18,174 tons, which is the same place as in the previous year, but with more than double 1888's output. Messrs. Jonn Blumer & Co., North Dock, rank next with 9 vessels of 15,296 tons; then Messrs. Bartram, Haswell, & Co., South Dock, with 5 vessels of 11,917 tons. Messrs. Osbourne, Graham, & Co., North Hylton, have launched 6 vessels of 10,692 tons; Messrs. John Priestman & Co., Southwick, 6 vessels of 8,037 tons; Messrs. W. Pickersgill & Sons, Southwick, 5 vessels of 7,960 tons; the Strand Slipway Company, 4 vessels of 7,481 tons; and Messrs. S. P. Austen & Sons, 4 vessels of 2,550 tons. Ninety-nine of the vessels were screw steamers, and three were sailing vessels.

NEWCASTLE, 1st January, 1890.

The Christmas Holidays.—The recurrence of the Christmas and New Year festivities has temporarily dislocated trade arrangements in the district, work being almost wholly suspended in the shipbuilding, engineering, and other industrial establishments until January 6th. When business is resumed, pressure will, in many cases, be put on to make up for lost time, but it will be found difficult, if not impossible, to make good the losses caused to employers, workpeople, and the general public by such a prolonged stoppage of productive operations.

The Coal Trade.—The prices of all descriptions of coals are very firm, and for households an advance of 1s. per ton is being asked. The whole of the contracts for 1890 have now been allotted by the North Eastern Railway Company. The collieries of Durham, Northumberland, and South Yorkshire will be the sources of supply. The prices are nearly 50 per cent. higher than under the contracts entered into at this time last year, and which are now expiring. It is understood that a settlement of the Northumberland miners' claim for an advance of 15 per cent. in the wages rates will be arrived at on the basis of the employers' offer of 10 per cent. The acceptance of this offer by the miners involves the abandonment of their request to have the number of working days per fortnight reduced from eleven to ten.

Wages Movements.—The shipsmiths employed in the Tyne yard have accepted the arrangement already made with the platers, riveters, &c., by which an advance of 5 per cent. on piece prices, and 1s. per week on time wages, will become payable on the first pay-day in January. The platers' helpers have put in an application for an advance of 10 per cent., to fall due on January 24th. The enginemen, cranemen, cartmen, and general labourers at Messrs. Abbot's works are on strike for an advance of wages, but the firm, having made them a reasonable offer, which was refused, now seem to be determined to dispense with their services, and have already made arrangements which will have the effect of permanently displacing at least one section.

Electric Lighting.—New works for the manufacture of electric lighting apparatus have been erected at Heaton by Messrs. C. A. Parsons & Co., and operations on an extensive scale have been commenced. Among the earliest contracts executed by the firm is that for the whole of the plant required by the Newcastle and District Electric Lighting Co, Ld.

DUNDEE, 1st January, 1890.

Flax and Jute Trades.—Business is at a standstill at present on account of the holidays. The year 1889 has been, on the whole, a prosperous one, so far as the local industries are concerned. Prices close below those which were obtainable at the beginning of the year, but the average of the twelve months has been remunerative. The importation of jute, 214,353 tons, is the largest on record, if we except that of 1883, which reached 233,883 tons. In 1888, there were 188,659 tons imported. Prices have been pretty well maintained, notwithstanding the increased supplies. At the beginning of the year quotations were from £10 10s. to £17; they are now from £11 10s. to £19. Spinners are not believed to be well supplied. In yarns a very good business has been done throughout the year, and there has been a large demand for export as well as for home consumption. Rates do not, however, close so high as at the end of last December. The quotation for 7lb. fine yarns was then from 1s. 8d. to 1s. 9d.; it is now from 1s. 7½d. to 1s. 8d. For the last weeks of the year the demand for manufactured jute goods has not been up to expectation, but makers are hopeful that the spring demand will be brisk. The feature of the year's trade is the increased attention given to carpets and other fancy goods. It is on the development of the manufacture of fancy articles, perhaps, that the permanent improvement of the jute trade largely depends. Prices of Hessians are about ⅜d. under the closing rates of 1888. The linen trade has not been equal in extent to that of that year. Indeed, the importations of flax, tow, and codilla are below the average of the last four years. In 1885 the imports of flax amounted to 28,474 tons; in 1886, to 20,215 tons; in 1887, to 28,570 tons; in 1888, to 31,060 tons; and in 1889, to 25,673 tons. In 1885 the imports of tow and codilla were 4,800 tons; in 1886, 5,388 tons; in 1887, 6,016 tons; in 1888, 7,580 tons; and in 1889, 4,797 tons. Prices of most qualities are from 10s. to £3 under the closing prices of last year. Tows show a decline of from £4 to £5. The prices of yarns are also lower. The price of 2lb. flax is 1s. 4d. to 1s. 4½d., against 1s. 5½d to 1s. 6½d; 3lb. flax is 1s. 7d. to 1s. 7½d., against 1s. 9d. to 1s. 10d.; 3lb. tow is 1s. 5d. to 1s. 6d., against 1s. 6½d. to 1s. 8d.; and 6lb. tow is 2s. to 2s. 1d., against 2s. 4d. to 2s. 6d. The importation of foreign (French) yarns has increased the downward tendency of prices. The business in linen goods has been, on the whole, satisfactory. Merchant navy canvas is quoted at 7½d. to 7¾d., against 7¾d. to 8d. at the corresponding date last year.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, Bedford Street, Strand, London, W.C.*

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," at our London Offices, 358, Strand, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

BOUND VOLUMES OF Industries,

In half calf, gilt lettered, may be obtained at our London, Manchester, and Glasgow Offices, Price 20s. each.

Industries:

FRIDAY, 3RD JANUARY, 1890.

THE TRADE OF THE PAST YEAR.

Two years ago, when reviewing the trade of the year 1887, we noticed that the autumn revival of 1886 had been short-lived, but that towards the close of the following year a fresh revival of trade, which bade fair to last long, had begun. This anticipation has been so far justified by events, for since the late autumn of 1887 trade, both foreign and domestic, has been progressing by leaps and bounds. The rumours of Continental imbroglios have been falsified, and even the deposition of an Emperor and the establishment of a Republic in Brazil have passed almost unheeded in the press of business. The trade of the year has been brisk beyond precedent, and, although not improbably some of the production which is being carried on so rapidly is at least premature, there is, for the time at all events, ample margin for capitalists and labourers alike to lay by against the "rainy day" that sooner or later must come. The incidents with which we are familiar in times when the curve of trade tends upwards have been fully manifest during the past year. General wholesale prices, which had been, with a brief check in 1873-82, falling steadily from 1874 till 1886, began to rise towards the close of 1887, and have continued to do so till now. Prices of staple commodities also have in some cases advanced very rapidly. In the beginning of January, Middlesbrough pig iron warrants stood at 33s. 10d., and Scotch warrants at 41s. 7d. The stocks were 250,215 tons and 1,032,123 tons respectively. The year had scarcely begun when orders from abroad came pouring in; the demand for steel-making, consequent upon the rapid revival of the shipbuilding industry on the Tyne, the Clyde, and the Mersey, drew off production, and checked the accumulation of stocks. Soon the stocks were encroached upon; prices rose rapidly all summer and during the autumn. The pig iron ring at Glasgow was in a chronic state of excitement, the Christmas holidays finding prices 61s. 7½d. and 61s. 2½d. for Middlesbrough and Scotch iron respectively, and the stocks reduced to 179,036 tons and 945,608 tons respectively. The aggregate decrease in stocks was thus upwards of 158,000 tons, and the advance in prices 80 per cent. in Cleveland iron and 50 per cent. in Scotch iron. This rapid advance was fostered by speculative outsiders, who rushed into the market and contributed an element of uncertainty and insecurity. It was even rumoured for a time that a syndicate contemplated a "corner" in Cleveland warrants, and transactions lent some colour to this rumour. One of the chief financial events of the year was the collapse in March of the Copper Syndicate, and the consequent ruin of the Comptoir d'Escompte of Paris. The financial crisis in France which followed affected to a considerable extent financiers in London and Glasgow who were involved in copper speculations; but the state of trade was too stable at the time for even such an untoward circumstance having any very widespread or lasting effects. Shipping was among the earliest of trades to feel the impetus of revival. The enormous expansion of the railway system in the United States and in Canada, the development of the South American Republics—especially the Argentine—and the rapid increase of Indian external commerce brought demands for ships which the existing tonnage could not cope with. Then shipbuilding, marine engineering, steel smelting, and the numerous complementary industries of these groups shared the expansion, and during the whole year every resource of these trades was taxed to the utmost. On the shipbuilding rivers, as the year closed, yards which had been disused during the depression had been reopened, new firms had been established, and every slipway was occupied. General wholesale trade, not so readily followed in detail as those great staples which bulk largely in the public eye, has benefited also. Increased work, increased wages, and increased spending power has enabled the great body of consumers to increase effective demand, and has thus reacted upon production, accelerating the rate of revival and tending to make it more lasting. These industrial impulses have, as was to have been expected, strained the resources of the companies in whose hands are the means of inland transit. Not only have the railway companies benefited very largely by the increase in the volume of trade—so largely indeed that they have been paying, for them, large dividends, and have been able to make permanent reductions in their expenditure, by effecting favourable financial changes—but they have been compelled, as well as enabled, to increase their power of meeting the large demands upon their resources. The ensuing session of Parliament will witness what may well be called a railway mania, for not since the memorable days of forty years ago will so many railway bills have been brought before it. In the near future also there lies the enormous possibilities opened up by the prospect of supplying China with railways. A momentary hitch seems to have taken place, owing to the reluctance of the Chinese to admit the foreigner to the share in administration which would be demanded if foreign capital were used in the construction of railways. But this difficulty will doubtless be got over, either by the capital being found in China itself—for the Chinese are born speculators, and a Chinese railway mania which should draw the cash from the pockets of the small Celestial investor is by no means beyond the bounds of probability—or by the Chinese Government borrowing the money in London on its own credit. The latter it could easily do, for the last China loan was quickly placed, the total indebtedness of the country being rather less than its annual customs revenue. Though the exploitation of the transit system of China by European capitalists would be more rapidly carried out than would be the case if it were left to native administrative sagacity, with its dignified Oriental deliberation, there is a good deal to be said for the latter course, from the point of view of its effect upon European trade. Two important incidents of the year, in connection with international commercial relations, are the prolongation of the contest between Germany and England for the trade of the Eastern Coast of Africa, and between Portugal and England for the trade of the West Coast. Both cases illustrate the circumstance that the explorer as plenipotentiary and administrator is not always a success, since the qualities of physical endurance and braggadocio which are indispensable in the rôle of the first are generally secondary at least in the rôle of the second.

The most considerable industrial phenomenon of the year has been the prevalence of strikes. The rise of prices which brings increased profit to the employer, provided the rise in the prices of raw materials is not out of proportion to that in the prices of the finished product, brings increased expenditure upon the workman, and thus, from the Ricar-

Digitized by Google

dian view of the law of wages, a rise of wages is an inevitable result. Such direct relation between cause and effect is understood well enough by many employers, and thus in some industries advances were, with much foresight, spontaneously offered. Whether or not the claims of the men were just claims, in those cases where the demand for increased wages was not granted, need not be discussed here, but the *rationale* of these claims is not far to seek. Advance of prices all round, rise in wages in many trades, a general feeling that wealth was being produced in which the smallness of their share was only too manifest—these were considered quite sufficient grounds upon which to demand advances. Perhaps if one had been asked to mention a case in which an effective demand for increased wages could not be made unless the employers were entirely agreeable to grant it, the case of the dock labourers in London would have been most unhesitatingly given. Yet the dockers struck, remained out five weeks, their committee meanwhile supporting nearly all the waifs and strays of the London streets, and then the dockers went in with an advance of wages. It would be futile to omit to draw the obvious conclusion from this and from other similar cases. Depression of trade and falling off in prices inevitably result in the forcing down of wages. Revival in trade and advance in prices just as inevitably result in advance in wages. But the strikes convey another practical lesson. Without in the least criticising the conduct of the dock directors, or others who may now be placed in similar circumstances, the conviction has forced itself upon the public mind that such disputes must not be allowed to go too far. That, when a dispute about wages results in the stoppage of a great industry, in interference with the means of transit, or in curtailing the supply of such essentials to life, under modern conditions, as gas or water, it is time for some one in the public interest to step between masters and men, and say: "We cannot permit this war." This conviction has been growing. The success of the small committee of arbiters which met at the Mansion House and settled the dock strike has encouraged the London Chamber of Commerce, as indicated in our columns last week, to suggest the formation of a permanent Board of Conciliation. This cannot be too strongly commended. It has been the fashion to sneer at such attempts as being praiseworthy, but sentimental and unpractical. They are really intensely practical and far-seeing. The evil day when prices go down, and wages must go down, cannot be very far a-head. Strikes will hasten its coming, for every strike means cessation of spending power and crippling of industry—a strike of one trade means a lock-out of another. Arbitration, therefore, as a means of settling wages without stopping production is not an expedient of sentiment; but a definite attempt to introduce order and system into what has hitherto been disastrously anarchic. The year 1889 must, from the point of view of industrial organisation, be regarded as the starting point of a new epoch, for, if it has seen the largest strike on record in this country, it has also seen a most successful effort on the largest scale to reconcile the conflicting interests of labour and capital.

The probable future of trade is a topic upon which we would rather avoid entering. To prophesy correctly we must know, and there is no knowing. There are, however, some elements of danger in the offing. Are we producing too much for use as fixed capital? Are the South American Republics not over-railwaying themselves? Are America and Canada not calculating too much on the continuance of grain and cattle shipments to Europe on the present large scale? A collapse in America would certainly affect us very seriously, since a large part of our increased trade has been with the United States and Canada. Are we not also, as indicated above, going with our eyes open into a new railway mania, in which immense sums will be locked up in an unrealisable form? There is besides an element of danger in the immense nominal increase of capital invested in joint-stock companies, amounting, during the past year, to upwards of two hundred millions. A large part of this is really due to enhanced valuation on the properties in question; yet interest is expected upon these inflated sums by the investors, and, if it be not earned, there will be corresponding hardship. To the large capitalist this is a matter of comparatively slight importance, but to small holders restriction of dividends means proportionally a much larger restriction of spending power. Thus, the increase of the number of stockholders involves increase of sensibility in the commercial balance. There is besides another danger, which is almost always left out of account in purely commercial forecasts—that is, the rate of increase of the population. It goes without saying that sudden bursts of prosperity result in an increase of marriages, and the offspring of these marriages pass their non-productive years generally in the periods of depression that follows the periods of inflation. They are thus a charge upon their parents and upon the community at a time when both are least able to bear extra burdens. Thus periods of depression are inevitably lengthened, and their intensity deepened, by legacies from the periods of inflation which preceded them. The circumstance that the revival has been in progress only two years, that it has slowly emerged from a period of depression, and that meantime all looks prosperous, encourages us to hope that a wild spirit of speculation may be avoided, and that the normal result of a moderately increasing population and a greatly increasing power of production will be brought about—viz., increasing comfort among all classes of the people.

PROFIT SHARING.

Mr. David F. Schloss has contributed a thoughtful and interesting article on the above subject to the *Charity Organisation Review* for the present month. After describing several instances of profit sharing, Mr. Schloss goes on to say: "The price of the craftsman's labour is its wage. Profits are the price of another kind of labour. Profits are the piece-work wages of management. The main test of the fairness and efficiency of any method of industrial remuneration is that it succeeds in securing a just proportion between the price of labour on the one hand, and the quantity and quality of that labour on the other, including in the elements which go to make up the quality, not alone careful workmanship, but also the avoidance of waste. What we want, in fact, is payment by results. Now, all forms of piece-wage involve payment by results, the remuneration of the workman being proportionate to the quantity of the work performed, and also to its quality, so far as this quality can be ascertained by the critical inspection of an experienced foreman. The avoidance of waste can be promoted by prizes for economy (as, for instance, those paid to engine-drivers on many railways for economy fn the consumption of coal and of oil). These methods are applicable in the case of men working single-handed; in that of men working in groups advantage is taken, under a variety of appropriate methods, of the well-known fact that six men, working together with the prospect of a joint reward of a given amount, will render services more than six times as valuable as each would render if working separately with the promise of a reward equivalent to one-sixth part of that amount; every man acting, in effect, as a foreman in relation to the labour of the other five, and stimulating them to display the utmost possible degree of carefulness and zeal for the common good. Now, while it is to this fact that the system of profit sharing owes a great part of its economic value as a means of inducing the exhibition of special assiduity by the employés, all these types of collective piece-wage possess, from the point of view of equity, this marked superiority over profit sharing, that by them the remuneration of the labour of the employés is made wholly independent of the ultimate financial results of the business—results which depend, in the main, on the skill and industry, not of the workmen, but of their master.

"On the other hand, there are certain cases in which the profit sharing method, in respect both of fairness and of economic efficiency, undoubtedly surpasses any form of the wage system. In particular instances it may be impossible to measure the extra value of special zeal and of special care otherwise than by the figures of the profit and loss account of the firm: in these instances, accordingly, the system of industrial partnership may, in the true interests of both the employés and the employer, reasonably be preferred to any other.

"So much as to the logic of profit sharing. But the consideration of the claims of this method would be incomplete if we ignored the high practical value which it derives, not from its fulfilment of the demands of reason, but from the satisfaction which it affords to popular prejudice. The working classes in general object to the scale of the remuneration which they receive as unduly low; but still more does a considerable section of the working classes object to the form of this remuneration as inconsistent with the dignity of labour. What these men yearn for is, not so much a rise in wages, as a radical alteration in the position of the working man, which shall convert him from a 'mere wage-earner' into an 'associate' entitled to participate in that coveted fund, hitherto monopolised by the middle-class capitalist—'the profits of industry.' To persons imbued with an ambition of this character the benefits—shadowy as they may turn out to be—promised by this novel and elaborate method of industrial partnership, especially when coupled with the constitution of some sort of consultative committee of the employés (which, of course, is never allowed to possess any but a nominal influence in the management of the concern), will appear infinitely more attractive than any advantages, however substantial, which might be secured for the workers by any form, however equitable, of the simple, old-fashioned, well-tried, but despised and detested, wage system. Outside the world of the working classes the conversion of the profit-making *entrepreneur* into a salaried official is a matter of more and more frequent occurrence, the small shopkeeper being turned into the manager of a department in the service of 'the Stores' or of a Universal Provider, and the owners of the big breweries, and so on, becoming the managing directors of the limited companies to which they have sold their concerns. Nor do the persons thus degraded into 'mere wage-earners' appear to feel any very acute degree of humiliation. But the love of independence which characterises the industrial classes not unrarely causes them to chafe under the yoke of 'service,' and to embrace with avidity the opportunity of posing as partners with their masters, which is afforded to them by this ingenious system of profit sharing."

AN IRISH INDUSTRIAL LEAGUE.

An influential Provisional Committee has been formed to promote an Irish Industrial League, and, having regard to the non-political and non-sectarian character of the undertaking—which is well shown by the list of members of the Provisional Committee—we heartily wish this latest attempt to give life to Irish industry every success. A general meeting of subscribers and members will be held in Dublin during the first week in February for the appointment of central offices, district committees, and officers. The Rev. Canon Bagot, of Kildare, is one of the hon. secretaries, and also provisional treasurer.

The following prospectus has been issued by the Provisional Committee:—

The Irish Industrial League is formed to better promote the development of the material resources of Ireland, hoping thereby to provide remunerative employment for our artisans and labourers. The League is formed on a strictly non-sectarian and non-political basis, and in order that all may join, 5s. per annum is fixed as the subscription. The Executive of the League will consist of a Central Council and committees in every district in Ireland. The duties of the Council will include receiving reports from the various committees on the industries which can be profitably introduced, as well as on those which from one cause or another are languishing or dormant, but are capable of being established on a sound financial basis; also as to the water-power available in their respective districts, and what railway and other communications are at present in existence, and how far these can be improved. On receiving these reports the Council after due and careful investigation will make their report to the public, and suggest the best means of carrying out their recommendations, having regard to such industries only as can be profitably promoted. Special committees will be formed from time to time of members of the League who are known to be more or less experts on particular industries.

The following, among others, are the industries that will receive the special attention of the Council, viz.:—

Textile manufactures,
Minerals and mining,
Quarries and clays,
Milk and dairy produce,
Development of dead meat traffic,
Fruit and vegetable farming,
Agricultural development,
Fisheries, internal and seaboard,
Poultry farming,
Forestry,
Osier-growing and basket-making, &c., &c., &c.

The League also hopes to take up the question of industrial education in primary schools.

The Committee trust that the ramifications of the League will

Digitized by Google

extend throughout every district in Ireland, and as their sole object is to increase the material wealth and prosperity of the country, they hope it will receive universal support. As soon as the League is fully organised public meetings will be held throughout the country to explain more fully its objects, and also to receive suggestions from those who attend. Applications for membership will be received by any of the hon. secretaries, and until the appointment of treasurer the Rev. Canon Bagot, Kildare, will receive and acknowledge subscriptions.

Letters to the Editor.

THE CHANNEL BRIDGE.

To the Editor of "Industries."

Sir,—Your article on the subject of the means of communication between England and France is extremely interesting, as it affords a history of the various schemes which have been brought forward for crossing the Channel by other than the ordinary mode of conveyance, but those of a superstitious frame of mind will deduce a moral therefrom injurious to the latest project, as the whole of the previous proposals, with the exception of the "Calais-Douvres," have either proved abortive or else failures. I do not assert that this is any logical reason that the Channel bridge will come to nothing, but it may affect the investing class, which is an important matter.

One point upon which you have not touched, but which would have an important bearing if the project ever reaches the Parliamentary stage, is the effect upon the shipping of the Channel. The shipping interest has enormous influence in this country, and it may be expected that it will vigorously oppose the obstruction of navigation which will result from the formation of 120 islets between England and France. The knowledge, in thick weather, that this obstacle is ahead, will not have a reassuring effect on the mind of the average mariner. The matter has been pithily expressed—I forget where—in the statement that had there been a natural obstruction of a similar nature, engineers would have busied themselves long ago in devising a method of getting rid of it. Another question to be considered is whether the bridge would pay. You give the estimated cost at £34,000,000. As estimated costs and actual cost go in such matters, it may be taken that £50,000,000 will be near the mark, and it is exceedingly doubtful whether, after allowing for cost of maintenance and working expenses, the traffic would give a return which would pay a reasonable rate of interest even on the lower of these sums. As an engineering exploit the bridge would be a desirable monument, but as a commercial speculation I think it is less to be wished for.

Yours, &c.,

Speculator.

London, 30th December, 1839.

THE GAS STOKERS' DISPUTES.

To the Editor of "Industries."

Sir,—The letter of Mr. Charles W. Rausch, in your issue of the 20th inst., is interesting, because it is written from a point of view of the relations between capital and labour which is falling into abeyance, or even, perhaps, becoming obsolete. This point of view, though hitherto common enough, is essentially one-sided. It goes without saying that the perfectly fair objection to the importation of sentiment into the discussion of such problems cuts both ways. The plea that employers should be permitted to "conduct their business" as they please—that is, without regard to their employés or to anyone else—is simply a sentimental plea. No one is independent of the obligations of contract, or of law, or of public opinion. Wages imply a contract between employer and employed, and a wages question is not exclusively the employer's business, but is of necessity a business in which the other party to the contract must have something to say. The course of events in this case seems to have been something like this:—The men were employed on certain terms; afterwards the directors of the Gas Company announced that they were about to alter those terms, adding that if the men did not agree to this alteration they might go. The men did not accept the terms, and they went. This is not a strike; it is, in effect, a lock-out. The men may win, or the company may win; but either way it is not a foregone conclusion that the company were right, any more than that the men were right either morally or as a matter of policy. If a public company, or indeed a private individual, may do as they please, then justification of any action of theirs is unnecessary; but the Gas Company do seek to justify themselves, and thus they voluntarily place themselves before the bar of public opinion. An employer may justly or unjustly dismiss a single employé without incurring almost any risk of attracting public attention; but he cannot lock out several hundreds without the fact becoming notorious, and the importunate question being put, Why?

In this case, the Why? is answered apparently truthfully, by the statement that the men had formed a union which the employers were desirous of breaking up. Here, then, on the face of it, is an interference by the employers in what is an affair of the men. If they choose to form a union, they were simply acting within their legal rights, and were only following the example of almost all tradesmen, skilled and unskilled. Suppose, for a moment, that the case had been reversed: that the company had elected to combine with other gas companies in order to form a gas syndicate, would they have consulted the men or would they have submitted to the imposition of the men's dictation of conditions which would infallibly break up the proposed union?

This anti-combination idea cuts both ways. It is too late in the day to oppose the principle of trades unions, just as it is too late to object to the development of joint-stock enterprise. These two examples of combination have together brought about a great change in the markets. At a particular moment the combination of capital secures the buyer or the seller, as the case may be, in a strong position. So far as labour is concerned, the trade union has undoubtedly made labour a stronger seller than before. Employers may not like this, but it is a patent fact. "Platitudes about peace," then, must come in; the arbitrator must take the place of the strike committee. Wages questions must, for the sake of both sides, be discussed quietly, and not with strife, and arbitrary and unreasonable action on either side avoided because it is against the best interests of both. To plead that it is illegal or immoral for the union "to order what men shall or shall not be employed by the Gas Company" is quite beside the question. The men may or may not be acting wisely in rejecting Mr. Livesey's proposal, but they see, what he must have seen when he made it, that its acceptance involved the breaking up of their union, and, having just formed this union, they determined to resist this attempt to smash it. Their position is a perfectly tenable one; whether, however, the balance of advantages was on the side of striking or on that of submission I am not prepared to say.

Yours, &c.,

T. M.

MACHINERY FOR TREATING ARROWROOT.

To the Editor of "Industries."

Sir,—If any of your readers could tell us to whom to apply for particulars of machinery for grating and treating arrowroot and cassava, we should be very much obliged.

Yours &c.,

W. R. Dell & Son.

26, Mark Lane, London, E.C.,
January 1st, 1890.

ENGLISH *VERSUS* GERMAN TORPEDO BOATS.

To the Editor of "Industries."

Sir,—I have read with great interest what has appeared in your issue of the 27th inst. in reference to English and German torpedo boats. I am myself of German extraction, was educated in that country, and, besides, employed there for many years as an engineer. I am now interested in the study of torpedo boat design in this country, and consequently feel myself very unbiassed in this discussion, as my sentiments in some respects lean toward the Germans, and in other respects toward the English. I am very well acquainted with the torpedo boats built both in this country, Germany, and France.

What I believe to be the case is that the German constructors are far more clever than the English in pushing their business, and they are also powerfully supported by their Government, which has constituted itself a gigantic agency for promoting by any means in its power German industry. To these two causes must be mainly attributed the recent successes of German manufacturers, and no doubt the cheaper labour obtainable in Germany enables them to construct at lower prices: but in point of quality the English undoubtedly maintain the lead.

Regarding the question of speed, I do not believe there is much to choose between Thornycroft, Yarrow, Schichau, and Normand. That is, on a given length. We all know that with the larger, or longer boat, if the power is proportionate to its displacement, it will, as a matter of course, have a higher speed than the shorter one, and in the table which you give on p. 609 this fact is simply confirmed by the figures. The Schichau boat appears to be the fastest, but it is at the same time the longest. The slowest boat, which is also German, is the shortest, and the other ones have intermediate speeds and intermediate lengths. The real point in regard to speed, so far as the credit of the builder is concerned, is to obtain the highest speed for a given length, because length determines speed with similar model and proportionate power. I believe I am correct in saying that all the builders named above are practically on the same level, provided the speeds are tested over runs of long duration.

There are, however, many other things besides speed to consider. There is the question of rapidity of manœuvring, and in this respect Yarrow & White are far ahead of all others. In the last boats built for the British Government by Yarrow, which are 130ft. in length, the speeds varied from 22½ knots to 23 knots, carrying a load of 20 tons on a run of three hours' duration, and the boats were capable of turning in a circle having a diameter of twice the length of the vessel. This combination of speed and manœuvring power has never, to my knowledge, been surpassed or even equalled before in a boat of these dimensions.

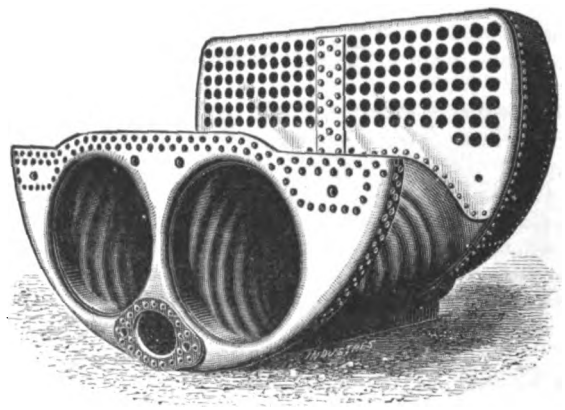
Touching the question of stability, which seems of late to have come prominently before the public, no doubt Schichau and Yarrow come first. The French boats are notoriously very deficient in beam—in fact, too narrow to be thoroughly safe under all conditions. One remarkable point in the Yarrow boats is the fact that the rudder and stern is so designed that, when turning, the action of the rudder on the hull has a tendency to keep it upright and to counteract the centrifugal force which otherwise would cause the vessel to heel outward, which is one of the sources of danger other builders have taken no steps to remedy.

In point of durability and success in continuous working, the two English builders and M. Normand undoubtedly come before the German firms. Not very long ago (referring to the boats built for the Italian Government by Messrs. Schichau) I saw two torpedo boats in Dover Harbour, and one of them had broken down. After being repaired they proceeded on their voyage, and they again broke down near Portsmouth, and had to apply to the English Government for permission to go into Portsmouth and get repaired in the dry dock, at which time the construction of the hull was severely criticised by the English authorities, some things having been made in cast steel which in English practice would have to be made of forged steel. The plating and riveting of the hulls were far from good. At any rate, they did not produce a favourable impression; also the skin plating of the hulls was not galvanised, while that of all English boats is always galvanised. I simply mention these points, but there are many others in which the German boats are defective.

Another fact is interesting, and adds to the reputation of the British builders (Thornycroft and Yarrow), and that is, they have never incurred any penalties for failure to get their contract speed, although they have built, as is well known, a very large number of torpedo boats, while Schichau has failed. I would particularly refer to their contract with the Austrian Government, on the trial of which some doubts had arisen in the mind of the Austrian authorities as to the accuracy of the trials, and a special commission was appointed for the purpose of verifying the same, when it was found that the speed obtained was considerably below that contracted for, and heavy penalties were incurred by the contractors. Failure to obtain the contract speed certainly cannot be considered a feather in the cap of the German builders.

The excessively fine entrance lines adopted by Messrs. Schichau may possibly avoid the conspicuousness of the bow wave, and is therefore a good point; but as regards speed and comfort I do not for a moment believe these to be any gain, and the accommodation for the crew, being forward, is thereby very much reduced.

I trust you will consider these few lines worthy of publication.



Yours, &c.,

F. W. Crohn.

London, December 31st, 1889.

THE "FARNLEY" BOILER FLUE.

The illustration below represents one of the latest designs of corrugated furnaces, and one in which the corrugations have a spiral arrangement around the flue. This furnace is made by the Farnley Iron Company, Ld., near Leeds, and the design is very neatly worked out, with the view of forming a flue which shall have maximum

strength, both radially and longitudinally. Now that the normal pressure in marine boilers is 160lb. per square inch, and much higher pressures are being recommended for marine purposes, the question of a reliable furnace becomes one of prime importance. We therefore anticipate that the furnace we illustrate will be extensively adopted, especially in connection with the higher steam pressures which now obtain in the best engineering practice.

THE ROYAL INSTITUTION LECTURES FOR JUVENILES.

On Saturday, the 28th ult., Professor Rücker, F.R.S., gave the first of a series of lectures on "Electricity," at the Royal Institution. The lectures were specially adapted to a juvenile audience, but there were also present a number of leading men of science. The lecturer, after a few introductory historical remarks on electricity, made several experiments to show how bodies charged with electricity attracted and repelled one another. He then demonstrated the conducting and non-conducting powers of various bodies. With regard to the question, What is electricity? the lecturer confessed that if he were asked this apparently simple question he could not give a satisfactory answer, although much was known about its action. Professor Rücker next brought before the consideration of his audience the question how it was that two bodies charged with electricity, yet being several inches apart, should attract or repel each other. What was the invisible connection between these two bodies? Some might think that air was the all-important medium, but by means of an experiment with Dr. Crook's radiometer he showed that this was not the case. The state of the space surrounding the electrified bodies was next considered, and by various experiments this space was shown to contain lines of force in certain defined directions. Professor Rücker concluded his first lecture by showing his own investigations on electrical stress. By means of the Nicol prism, he showed that the physical conditions and arrangements of liquids were changed by passing through them a strong electrical current, the electrical stress on the liquid having a similar result to that of the introduction of a crystal into a ray of polarised light.

In the second lecture, on the 31st ult., Professor Rücker proceeded to show the distribution of electricity on conductors. He charged a metal cylinder, and on testing showed electricity to be on the outside, not on the inside, of the cylinder. An experiment with a soap bubble and a pith ball inside demonstrated the same principle. So long

Digitized by Google

as the bubble remained unbroken no effect was produced upon the pith ball by electrical influences from outside. On the bubble being broken the pith ball was affected. When a body is electrified, he said, it depends on the shape of the body whether the electricity spreads uniformly all over it. In a sphere it is found to be uniform, but in a body of irregular shape the electricity was found to accumulate in those parts which are the most pointed. A series of experiments was then shown to demonstrate the effect which an electrified body had on the air and surrounding liquids by causing repulsion and setting up streams. The lecturer concluded by pointing out the different results which experiments of this kind would have if performed in very rare gases—the electrified particles of air causing phosphorescence. He referred with admiration to the investigation of the late Mr. Warren de la Rue on this subject, who had recently bequeathed the actual apparatus employed to the Royal Institution.

Practical Electrical Notes and Definitions. By W. Perren Maycock. London: E. & F. N. Spon. 1889.

This little work possesses the merit of clearly defining its scope by its title. It contains notes on, and definitions of a nearly all matters connected with the elements of electrotechnics, and should be, we think, of great use to practical men and young electrical engineers. The definitions are all as accurate as can be expected without entering into mathematical detail, except, perhaps, the definition of the joule, which, though scientifically accurate (since heat and work are mutually convertible), is expressed in a way which might lead the uninitiated to believe that the *values numerical* of the units are identical. The average current required by an incandescent lamp is given as one ampere. It might, perhaps, be wiser to give the watts per candle-power, as then the current for any incandescent lamp running at any e.m.f., could easily be deduced approximately. The book also contains a useful table giving several quantities connected with conductors. We think that possibly the value of this table might be enhanced if the figures in columns IV., V., VI., and VII. referred to column III., and also if it were stated for which size of conductor the value of the fusing current applies. Further, something appears to have gone wrong with column VIII. But no doubt all such oversights will disappear in the next edition. The work contains clear and instructive diagrams of the various systems of arranging conductors for supplying current to lamps of the various types of dynamo, an epitome of the recent investigations in the theory of lightning conductors, the "fire-rules" of the Institution of Electrical Engineers and of the Phœnix Fire Office, and many other important data.

Society of Engineers. Transactions for 1888. Edited by G. A. Pryce Cuxson. London: E. & F. N. Spon. 1889.

The question is sometimes suggested by thoughtless critics, "What is the *raison d'être* in London of an institution like the Society of Engineers, in view of such gigantic competitors—if such they can be called—as the Institutions of Civil and Mechanical Engineers?" The answer is that there is plenty of room for the co-existence of all these bodies, and that they fulfil to a great extent different functions. The Institution of Civil Engineers, as a rule, accepts only papers recording work actually carried out, and the same remark applies, under somewhat different conditions, to the Institution of Mechanical Engineers. It by no means, however, follows that, because a paper does not comply with the requirements of these societies, that it is on this account undeserving of publication; and, besides this, it is very desirable that opportunities should be given for the discussion of schemes and inventions before they are crystallised into accomplished facts. Such opportunities are provided by the Society of Engineers, of whose Transactions a volume is now before us. The inaugural address of the President, Mr. Arthur Thomas Walmisley, was in the main a general survey of recent engineering practice in various branches, introduced by a short account of the origin and progress of the Society, which was originally started in the year 1854, as the Putney Club. This Putney Club was formed out of the former students of the "College for Civil Engineers and of General Scientific and Practical Education," and subsequently developed into the Society of Engineers, which at the beginning of 1888 had a total of 382 corporate members.

The first paper is by Mr. Henry Faija, M.Inst.C.E., on "The Effect of Sea Water on Portland Cement," and was suggested by the failure of concrete work at Aberdeen, this failure having been attributed to the chemical action of the sea water. The author disputes the correctness of this view, and maintains that the magnesia, admitted to have been left in the concrete by the sea water, was already hydrated and perfectly harmless and inert, and that the failure was due to quite other causes. The other papers published are the following:—"Wimbledon Main Drainage and Sewage Disposal Works," by Mr. W. Santo Crimp; "Filtration by Machinery," by Mr. Edward Perrett; "Acton Main Drainage Works," by Mr. C. Nicholson Lailey; "Light Railways," by Mr. William Lawford; "Practice of Foundry Work," by Mr. H. Ross Hooper; and "High Pressure Steam and Steam Engine Efficiency," by Mr. W. Worby Beaumont.

The Development of the Philosophy of the Steam Engine. By Robert H. Thurston. New York: John Wiley & Sons. London: Trubner & Co. 1889.

Professor Thurston has done well to publish in separate form his interesting sketch of the history of the theory of the steam engine which was presented to the British Association for the Advancement of Science when holding its session of 1884 at Montreal. The paper was given a very favourable reception, and was selected for incorporation in full in the "Transactions" of that year. It has now been revised, and, with slight modifications and some additional matter, is now reprinted for more general circulation. Every treatise on the steam engine should have a chapter similar in design to Professor Thurston's paper, for the purpose of showing its readers the present position of the subject and its connection with its past development, for the only real way to have a clear understanding of any matter is to consider how it came to be what it is. We have very often pointed out the defects of the ordinary methods of treating the theory of the steam engine, and we think Professor Thurston has done good service in putting his paper in a convenient form, and thus made it accessible to students of the subject, who, in the meantime, may use it as a supplement to the ordinary treatises.

The author begins by pointing out that a complete history of the development of the steam engine would include—first, the history of the mechanical theory of heat; secondly, of the history of the science of thermodynamics, which has been an outgrowth of that theory; thirdly, the history of the application of the science of heat-transformation to the case of the steam engine; and fourthly, an account of the completion of the theory of losses by the more or less avoidable forms of waste, as distinguished from those necessary and unavoidable wastes indicated by the pure theory of thermodynamics; and the object of the paper is to collect into a condensed form, and in proper relations, those several branches of the subject. An interesting sketch is given of the development of the science of thermodynamics, which deals impartially with the different distinguished men who have helped that development, and has avoided all personal or party feeling—for there are scientific as well as political parties. For instance, while giving full credit to Joule for his distinguished work, he has not overlooked the merits of Mayer, and naturally he gives prominence to the investigations of Rankine, Clausius, and Sir W. Thomson. In the application of thermodynamics to heat engines he points out that the germ of the science of the steam engine is to be found in the work of Sadi Carnot, published in 1824, and traces its growth through De Pambour and Tate to Clausius and Rankine. He gives an outline of the work of the latter, and points out its neglected elements and the difficulty of arriving at any exact theory about them. Since Rankine's time the thermodynamic theory of the steam engine has received no important modifications, and the work of later engineers, and of physicists working on the general subject, has been confined to the study, experimental or other, of the limitations set to the application of this theory by the influence of other physical phenomena. Professor Thurston points out the share taken in the investigation of the nature of these limitations by Hirn, Clark, Isherwood, Cotterill, and others, and this part of the paper will be found most interesting and instructive; and the conclusion he comes to is that he agrees with Hirn that, in the present state of our knowledge, a complete theory of the steam engine is impossible, and that all that can be given is an experimental theory. A beginning has, however, been made in the final researches necessary for a complete theory in the experimental investigations which have been and are being made by many workers, and Professor Thurston says that it is to be hoped, if not expected, that an exact theory of steam engine economy may at some early date be produced, and that thus the engineer may be enabled to obtain solutions of all such problems as arise in steam engine design with all the precision that can ever be desired. He thinks that its final shape will probably be given by some such master of mathematical and physical science as was Rankine or Clausius. In the meantime, care should be taken that the results of experiments are put in such a shape that they can be successfully used by such a master when he appears. Professor Thurston's paper will be most useful in showing the steps which have already been taken, and indicating those which are necessary for future progress.

A Text-book of Assaying for the Use of Those Connected with Mines. By C. Beringer and J. J. Beringer. London: C. Griffin & Co.

Of all the branches of chemical analysis practised for the control of industrial processes none is of greater importance than assaying. The modern literature of the subject is, however, very unsatisfactory, for, besides Mitchell's treatise, which is too voluminous for the ordinary mine assayer, and the chapters given in Percy's works and in Phillips' "Elements of Metallurgy," there is no concise work that can be unhesitatingly recommended. The recent revival in the mining industry, which has given rise to a clamour for metallurgical literature, has no doubt led Messrs. C. and J. J. Beringer to attempt to provide a practical text-book for the assayer. Of their fitness for the task they have undertaken there can be no question, for Mr. J. J. Beringer, besides being a graduate of the Royal School of Mines, is public analyst to the county of Cornwall and lecturer at the Camborne Mining School, whilst Mr. C. Beringer has filled the post of chief assayer to the most important copper mining company in the world. Their book admirably fulfils its purpose. It is not confined to methods of estimating a particular metal by the agency of heat, but deals fully with wet gravimetric and volumetric processes. Indeed, it gives considerably more information of use to the assayer than is included under the strict meaning of the term "assaying." For example, cognisance is taken of the rarer metals, since their presence occasionally affect the accuracy of the assay. The work covers four hundred pages, the first eighty-six being devoted to an account of the principles on which assaying is based and the manipulation required, whilst the remainder of the work deals with the methods of estimating the various elements. Throughout the book the metric system of weights and measures is adhered to. This is undoubtedly a step in the right direction. The metric system must eventually be used in all analytical work, as is now the case in volumetric analysis. Many assayers still adhere to the English weights and measures in dry gravimetric methods, and in assays for commercial purposes it will always be necessary to compute in ounces per ton. Those who prefer to work with grains and grain-measures can use the figures given by the authors multiplied by ten. One feature of the book is of special value. Under the more important methods, the authors give the results of an exhaustive series of experiments they have made, showing the effects of varying conditions on the accuracy of the method. Such results are of the utmost importance, for the assayer has hitherto been apt to accept vague generalisations, or to deduce from analogy what the effect of an interfering substance will be. The authors insist that the record that the assayer makes of his work should be clear and neat, so that reference, even after an interval of years, is certain and easy. Their instructions as to the keeping of laboratory books and the filling-in of report forms will be found of great interest. At the end of each section practical exercises are given for the benefit of the student. The work must, however, in no sense be regarded as a cram book. The requirements of the assayer in industrial practice are kept in view throughout. We note, for example, useful information on the valuation of copper ores, on sampling a mass of material, and on approximately estimating with rapidity the proportion of carbonic acid in the air of mines. The electrolytic method of copper assaying, as practised at large works, is described at considerable length. It is gratifying to learn that it is rapidly taking the place of the inaccurate method of dry assay for the commercial valuation of copper ores. The Cornish method of assaying tin ore, of which an interesting description has been furnished by Mr. A. K. Barnett, one of the leading authorities of the Cornish tin industry, is shown to be by no means so imperfect as some writers would have us believe. It is certainly the most expeditious method of determining the commercial value of a parcel of ore, and this, after all, is the main object of all assaying operations. The only fault we have to find with the book is that there seems to be some uncertainty as to the amount of chemical knowledge expected from the reader. Thus, the statement that hydrogen is a gas (page 62) will certainly be unnecessary to anyone who has been capable of understanding the information given in the preceding pages. The book is well printed and bound, and the

THE FORTH BRIDGE.

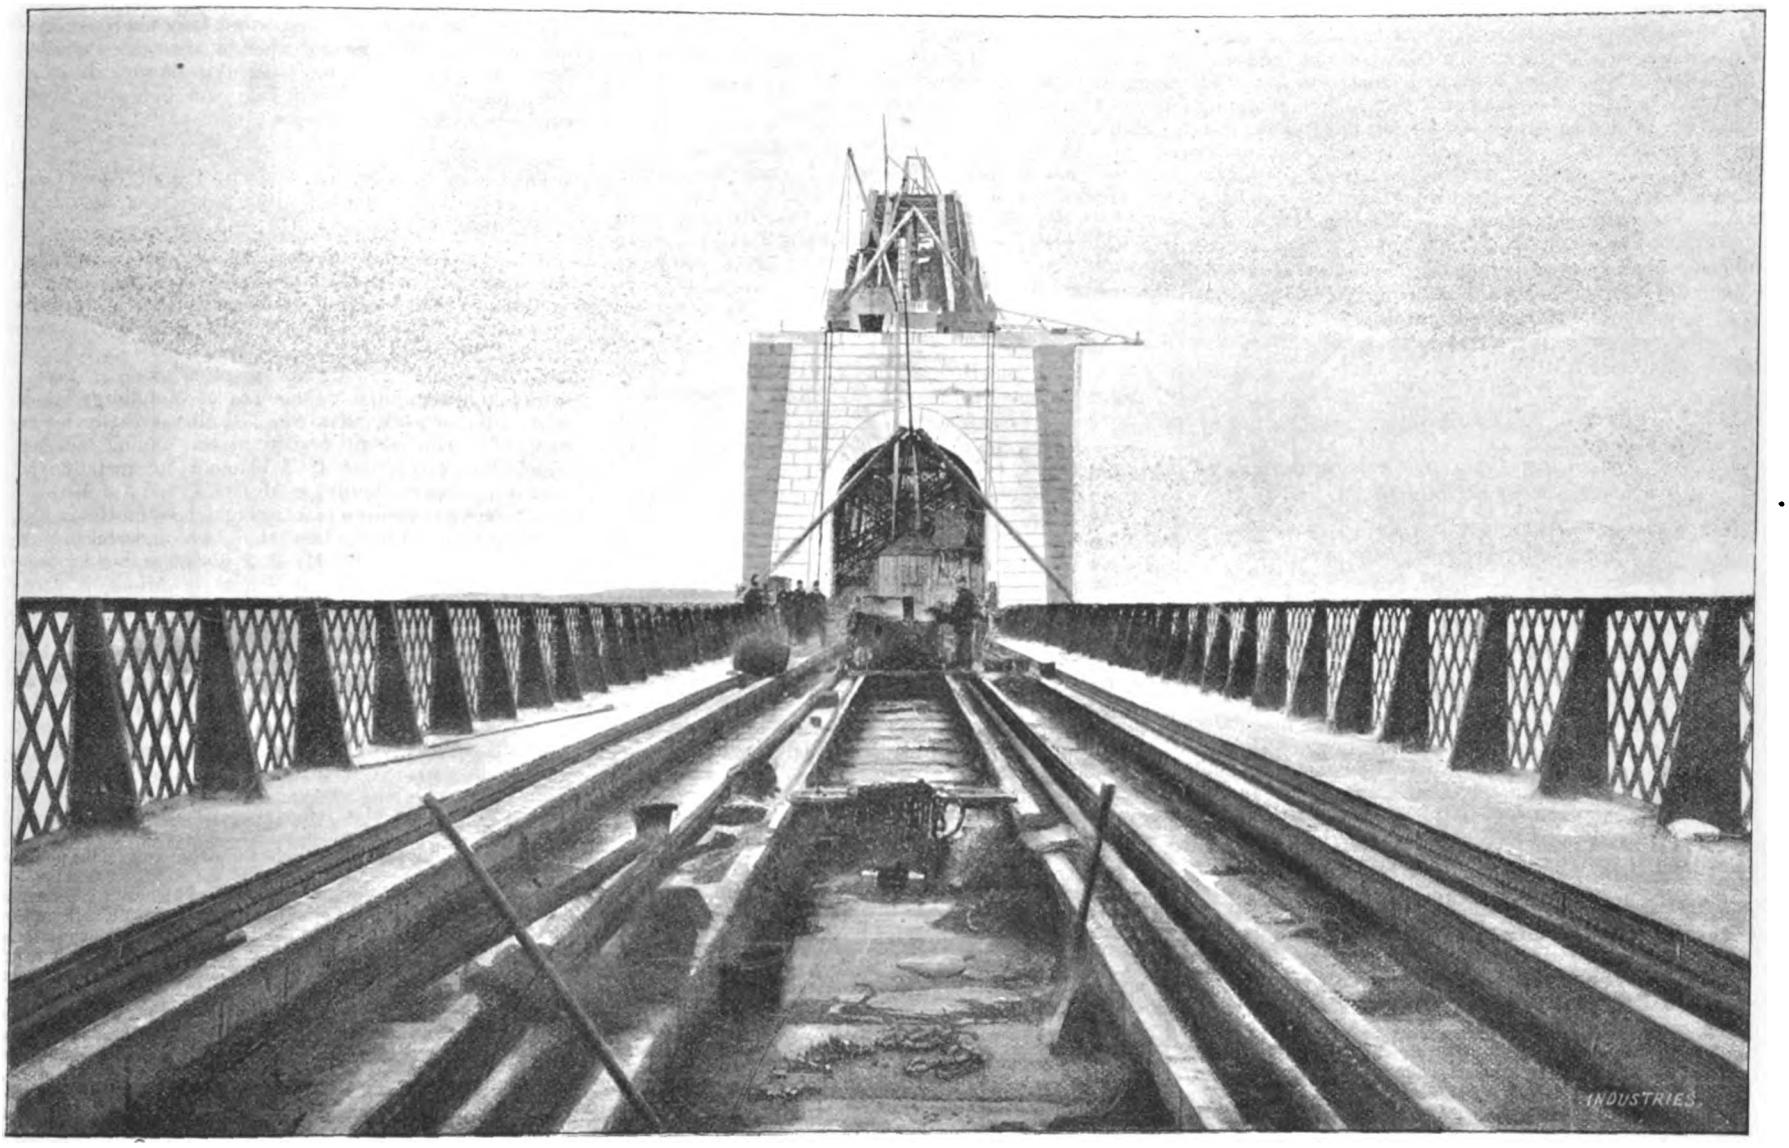

Fig. 2.—View on the South Approach Viaduct.

illustrations are numerous and carefully drawn in bold outline in vertical projection, the absence of unnecessary shading and perspective being greatly conducive to clearness. On the whole we can cordially recommend the book. The subject is treated in a practical and authoritative manner, and the work bears internal evidence of not being composed of mere extracts from other books. It conveys trustworthy information to the student, and, at the same time, contains a large amount of matter of interest and value to the practised assayer.

THE FORTH BRIDGE

In a recent number (see *Industries*, Vol. VII., page 357) we published an account of the central girders of the Forth Bridge, and the methods adopted in erecting them in position, and at the same time we reproduced some diagrams of exceptional interest, giving the exact longitudinal and transverse alterations of position made by the Queensferry cantilevers, so long as the end was free to move, pointing out at the same time that the figures were drawn by a giant arm, 670ft. in length, and weighing about 5,000 tons.

Since that time the bridge has been successfully completed, connection having been made on both north and south central girders; and we are now enabled, through the courtesy of the engineers, Sir John Fowler, K.C.M.G., and Mr. B. Baker, to place before our readers an illustration of the great work as an accomplished fact (see Fig. 1, page 12).

It is not to be supposed that a structure so widely known, and so conspicuous in the annals of engineering, should escape some criticism, if only on the score of its appearance. Accordingly, we find Mr. William Morris, at the recent Art Congress in Edinburgh, attacking the bridge on the grounds of ugliness. "There could never be," says Mr. Morris, "an architecture in iron, every improvement in machinery being uglier and uglier, until they reached that supremest specimen of all ugliness—the Forth Bridge." To such attacks on the part of the æsthetic school, Mr. Baker replied in his lecture delivered on the 27th November, before the Edinburgh Literary Institute, by pointing out that, in relation to the question of beauty, both size and fitness for intended requirements must have all possible weight. "The great Pyramids," said Mr. Baker, "would be regarded with deserved contempt if no bigger than haystacks." Aristotle held that great magnitude is, as such, an element of beauty, whilst Socrates regarded no object as in itself inherently beautiful, but that the attribute depended upon the impression made upon the mind receiving it. Mr. Baker passed on to point out that minds which had no conception of the duties which the great structure has to perform were utterly incompetent of judging what impression such knowledge had on those which did possess it and could appreciate the direction of the lines of stress and the fitness of the several members to resist forces. "I contend," said Mr. Baker, "that critics must first study the work to be done by both the piers and superstructure of the Forth Bridge, and the materials employed, before they can be properly qualified to settle the question of its beauty or ugliness."

This contention is supported, Mr. Baker concluded by remarking, by so eminent an authority on such questions as Ruskin, who says on the subject: "Of all the various principles of art, none are more indisputable, and few of more practical importance, than this. All art working with given materials must propose to itself the objects which with those materials are most perfectly attainable. Thus, great slenderness, lightness, or intricacy of structure—as in the ramifications of trees—is easily and perfectly expressible in metal work. The workman has not done his duty, and is not working on safe principles, unless he can so far humour the materials with which he is working as to exalt as far as he can their peculiar properties. If he is working in iron he should insist upon and exhibit its strength and tenacity, and he will invariably find the material grateful, and that his work is all the nobler for being eulogistic of the substance of which it is made."

Fig. 2 above shows the south approach viaduct, looking northwards. It will be noted that the rails appear in the foreground, the laying of which on teak sleepers inside guard troughs is being rapidly pushed forward. The rails are of the bridge type, 120lb. to the yard, a solid section, 146lb. to the yard, being used for making the expansion and contraction joints, which have received very careful consideration at the hands of the engineers. The rails were rolled by The Steel Company of Scotland, Limited, at their Heaston works, and the majority of them are now delivered at the Forth. Our illustration portrays the wind fence on each side of the viaduct girders, the teak handrails of which are being expeditiously fitted; and in the background will be noted the south cantilever end pier, the top cornice of which, of dressed granite, has yet to be built into position. Glancing at the approach railways, completion may be said to be seen very near. On the south approach railway, both the station at Rosshill and the Dalmeny bridge are nearly finished; whilst on the north approach railway the covered way and tunnels leave little further to be done, and the laying of the permanent way is well in hand. The direct line from Corstorphine to Dalmeny is well advanced, and the Carrickburgh branch is being pushed on with all possible speed.

In concluding, we may say that everything at South Queensferry is foreshadowing the end—as shown by the gradual dispersion of the men, the sales of plant, and the dismantlement of the workshops. The ancient and royal burgh of South Queensferry, after seven years of unwonted activity and prosperity, is gradually relapsing into its former placid slumbers. In a short time now little will remain to mark the busy toil and incessant labour carried on here since the beginning of 1883, save the gigantic structure to eastward, the fruit of so much skill, patience, and work—a triumph for all time of engineering progress in the nineteenth century.

IMPROVED HIGH PRESSURE MARINE BOILER.

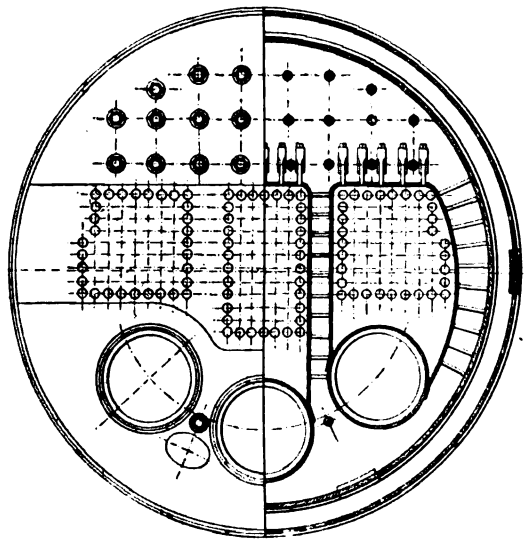

Fig. 1.—End Elevation—Half in Section.

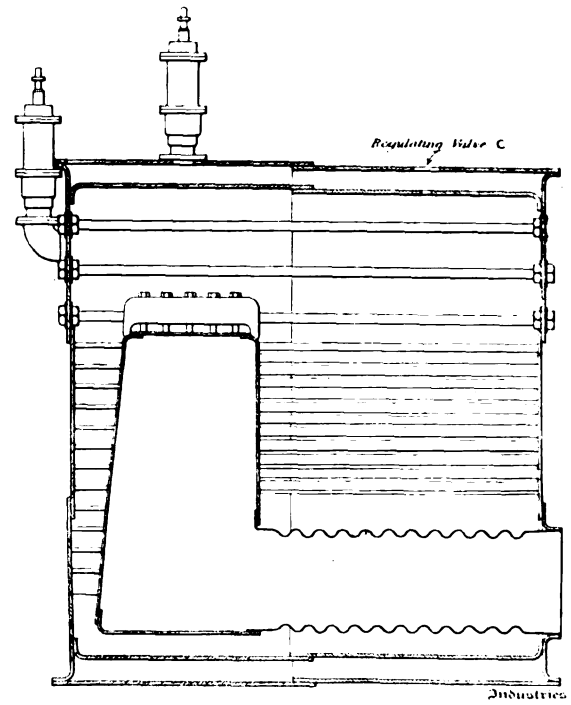

Fig. 2.—Longitudinal Section.

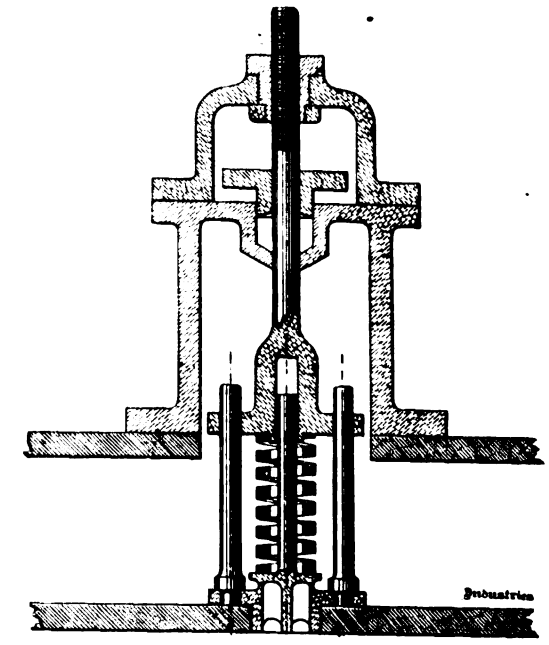

Fig. 3.—Transverse Section of Regulating Valve.

THE CONSTRUCTION OF MARINE BOILERS WITH A VIEW TO THE USE OF HIGHER PRESSURES.*

In placing before the members of this Institution a design of a new form of boiler suitable for higher pressures of steam than those now in general use, it would be as well for the writer, before explaining the design, to point out the many advantages, in his opinion, that would accrue from the use of higher pressures. During the last four or five years the struggle for economy has been marked by the extensive adoption of the triple expansion or tri-compound engine, working at pressures from 140lb. to 180lb. This type of engine has been almost exclusively adopted in new vessels, and in many instances compound engines have been converted into triple expansion by the addition of a third cylinder and higher pressure boilers. The well-known Trevithick was the first engineer to introduce steam of high pressure; and although his engines were non-condensing and his boilers of poor construction, yet he successfully proved their superiority in economy of fuel over the low-pressure engine, thus showing that steam of high pressure could be used advantageously; and when he and Woolf joined together in introducing the compound engine, it is said they used steam of 60lb. pressure. Steam of higher pressure than he ever anticipated is now being used, both with land and marine engines, and the object of this paper is to attempt to prove that steam of still greater pressures than those now generally adopted may be used with economical results, and that with few alterations the present type of marine boiler may be adapted to safely withstand these higher pressures.

The superiority of the triple expansion engines over the compound is due to the following causes:—To the higher pressure of steam used, and the higher rate of expansion consequent. Great variation of temperature in the cylinders, great initial strains, and sudden "drops" in the receivers are thereby avoided. These apply also to quadruple expansion engines. Increased pressure of steam is easily obtained by a very slight addition in the consumption of fuel, and the efficiency of steam rapidly increases with the increased pressure.

This may be proved thus:

1. The total heat of evaporation of 1lb. water from 100° Fahr. and at 312° Fahr. (80lb. absolute) is 1108·6° Fahr.
2. The total heat of evaporation of 1lb. water from 100° Fahr. and at 358° Fahr. (150lb. absolute) is 1122·4° Fahr.
3. The total heat of evaporation of 1lb. water from 100° Fahr. and at 401·1° Fahr. (250lb. absolute) is 1135·3° Fahr.

If in each case the steam be expanded to a terminal pressure of 10lb. absolute, the ratios of expansion will be (1) 8, (2) 15, (3) 25, and the mean pressures corresponding to these initial pressures and rates of expansion will be (1) 30·7, (2) 37·08, (3) 45. If the volume of steam varied exactly as the inverse ratio of the pressure, then these figures would give the comparative values of the steam at the pressures indicated. But as the volume of steam does not vary exactly as the inverse ratio of the pressures, the following will be found to be the more exact relative values in whole numbers: (1) 31, (2) 39, (3) 47. From this it will be seen that steam of 250lb. is capable of doing 20 per cent. more work than steam of 150lb., and steam of 150lb. 25 per cent. more work than steam of 80lb. The latter has been proved by actual practice, and is now an acknowledged fact. To use steam of 150lb. pressure with a compound engine would be very little more economical than to employ steam of 80lb., and the same may be said in the case of using any higher pressure than 160lb. for triple expansion engines. Yet when 160lb. pressure is used in the case of triple expansion engines, it may be said that there is a saving of 25 per cent. over the ordinary compound; and supposing a boiler was adopted with 250lb. pressure it might be anticipated with some certainty that a saving of 20 per cent. would be effected over the triple expansion engine. At the present time quadruple expansion engines are working at a pressure of 180lb. only. This is accounted for by the fact that hitherto it has not been found possible to construct a marine boiler capable of withstanding a higher pressure without either considerably reducing the diameter or increasing the thickness of the shell plates. With respect to the reduction of the diameter, it may be generally known that boilers of the locomotive type have frequently been tried, and many engineers are looking to this class of boiler as offering some advantages in point of weight in comparison to marine boilers, as well as their adaptability for higher pressures. Their performances have, however, not been found satisfactory, and in many instances where large boilers of this type have been in use they have had to be taken out and replaced by the ordinary type of marine boiler.

Two of the principal objections to the locomotive boiler for marine purposes are:—Firstly: That they require the purest of water, as from their construction they are much more difficult to clean and scale than an ordinary marine boiler. Secondly: They are apt to prime, owing to the small diameter and limited steam space, whenever the vessel is rolling and pitching in a seaway. Again, the writer questions very much whether this type of boiler, if required for a certain horse-power, could be made to occupy the same space of boiler room as a marine boiler of the same horse-power.

In a paper read before the Institution of Naval Architects by Mr. W. Parker, March 27th, 1885, he says:—"I have conferred with the principal steel makers in the kingdom on this subject, and am able to say that they agree with me, and are decidedly of opinion that steel shell plates of over an inch in thickness, and having a tenacity of over 30 tons, must contain so much carbon as to render them unsuitable for boiler-making purposes, although they may possess the necessary tenacity and ductility to withstand the usual tensile and cold bending tests." Since this paper was read, the uniform quality of steel plates for boiler making has considerably improved, and they are now able to turn out plates up to 1¼in. and 1⅜in. thick, but this is about the limit. Mr. J. T. Milton also remarks, in a paper read before the same Institution, March 30th, 1882:—"That these pressures of 140lb. and 180lb. are not likely to be increased for some time to come, unless some type of boiler is introduced which will not necessitate the present style of casing for containing the steam and water, nor the present method of internal firing, as with the obtaining pressures the thickness of plates for these portions have reached the maximum capable of being worked on the one hand, and of being used for the transmission of heat on the other." Taking these matters into consideration, it would appear that before higher pressures can be adopted some improved type of boiler is necessary to withstand these higher pressures, which must be so constructed that shell plates of excessive thickness are not required, nor has the diameter of boiler to be reduced.

Having regard to these requirements the writer ventures to introduce to your notice a form of boiler which will bear the strain of these higher pressures without increasing the thickness of shell plates, or reducing the diameter. In the accompanying illustrations Figs. 1 and 2 represent views of a boiler having two shells, which will hereafter be named as "outer" and "inner" shells. The space enclosed between the shells is termed a "jacket," so that the whole may be termed a "jacketed" boiler. The object of providing a double shell is to charge the enclosed space with steam of a lower temperature than that generated within the inner shell, which is thus relieved of the full pressure of steam within, and is only subjected to the excess of the pressure of steam within over the pressure of the steam between the two shells. As for example—in the illustrations we have a boiler with a shell calculated to stand a working pressure of 150lb. to the square inch, employed as the inner shell of a boiler in which steam is generated to a working pressure of 250lb., the extra 100lb. being neutralised or balanced by an external pressure of the same amount exerted by the steam enclosed between the two shells or jacket. As the object of providing a space between the two shells is to provide a means of applying a neutralising or balancing pressure to the inner shell, any fluid or gaseous body may be used, but for many obvious reasons steam is the most convenient for the purpose. It is at once evident that the pressure in the jacket must be constantly and regularly maintained, and in order to provide for this it is necessary to have one or more regulating valves between the two shells. These are constructed on the principle of an ordinary spring-loaded safety valve mounted on valve seats in the inner shell, and so regulated that when the pressure in the jacket falls below that required to be maintained the valve lifts, admitting steam from the boiler until the required pressure is reached, when the valve again closes. The valve in Fig. 3 is loaded to 150lb., and is externally adjustable. This is effected by having a screwed spindle passing through the cover by means of which the spring may be compressed or released as desired. A valve similar to Fig. 3 would be necessary to provide against collapse of inner shell, should the pressure in boiler from any cause be suddenly reduced. Safety valves of ordinary construction would have to be provided for both boiler and jacket. Condensed water would be drawn away from bottom of jacket to feed pumps. Tubes would have to be thicker, but not much more so than those required for 150lb. pressure, as their diameter could be slightly reduced. The same may be said of furnaces. These could be used of a thickness of ⅜in. and diameter of 3ft., and of a thickness of ⅞in. and diameter of 2ft. 6in., of Fox's patent corrugated type. Longitudinal stays would have to be pitched closer together, and of rather larger diameter, but they need not be of less pitch than 14in., which would afford ample room for examination and cleaning inside of boiler. Combustion chamber stays would have to be pitched closer together and of rather larger diameter. Tube plates need not be of any excessive thickness, if more screwed stay-tubes are put in. In fact, there seems to have been plenty of room for adapting the present style of marine boiler to higher pressures in all directions with the exception of the shell, and the writer is of opinion that a double form of shell, as shown in Figs. 1 and 2, would overcome this difficulty. Although a boiler with two shells will naturally weigh more than a boiler with one, yet the extra weight will not be so much as might at first be supposed, for by using steam of higher pressure a boiler of smaller diameter is possible, the weight of water evaporated being less. In this boiler there are two forms of riveted circumferential seams employed—one the ordinary lapped joint double riveted, and the other a flanged joint flanged externally in the case of the "outer" shell and internally in the case of the "inner" shell. The latter form of joint has been suggested in event of any difficulty being experienced in repairing an ordinary lap joint should occasion rise. It has been previously mentioned that this type of boiler is specially adaptable for steam of 250lb. for quadruple expansion engines which are at present only using steam of 180lb. This class of engine is becoming more popular every day, and may in time supersede the present triple expansion, even as the latter has taken the place of compound engines. The writer has not thought it necessary in this paper to go into all the minor details of a new design of boiler, but is anxious to have an expression of opinion from the engineering members of the Institution as to the feasibility of constructing a marine boiler with a double shell to stand much higher pressures than those now in actual use.

* Paper read before the North-East Coast Institution of Engineers and Shipbuilders, by Mr. Charles Bastow Casebourne, on the 16th ult.

ELECTRIC LIGHTING IN NEW YORK.

(From our New York Correspondent.)

UNDER the protection of the injunction granted by Judge Andrews against the interference with their wires by the Department of Public Works and the Board of Health, the electric light companies of the city used every effort to replace their old conductors with wire having more perfect insulation, in order to comply with the standard of the Board of Electrical Control. Having done this, the machinery was again started up; but all the regulations of the Board had not been complied with. Among others are the requirements that arc lamps shall be suspended at least nine feet above the sidewalk, and that all parts of the lamp with which a person is liable to come in contact shall be insulated. The neglect of these precautions led to the death of Henry Harris, on the night of November 30th. He and a fellow salesman were carrying a show-case from the sidewalk into a shop at 675, Eighth Avenue. The metal case of the frame came in contact with the protruding lower carbon of an arc lamp hanging but 100 inches above the walk. Harris had his left hand on the corner of the case, his left foot was on an iron plate in the walk, a nail in his shoe protruded through the sole inside—the contact was completed, and he was instantly killed. A few days later, lineman Clausen was killed while upon a pole in a similar manner to that of Feeks a few weeks ago.

These later accidents may have influenced the action of the Judges of the General Term, who, on December 13th, overthrew the injunction of Judge Andrews, as Judge Van Brunt said that "Human life is more sacred than the forms of legal procedure." On the following day the Commissioner of Public Works organised gangs of men, who, under the direction of Inspectors from the Board of Electrical Control, proceeded to cut down poles and remove wires wherever it was found that the regulations of the Board had been violated. This destruction of lines has now been going on for a week, and is likely to continue for a month longer. The confusion into which the circuits have been thrown by the reckless work of those who were unfamiliar with the systems, has led to a practical abandonment of arc lighting in the city, and the companies are discharging a portion of their force. The Westinghouse Company, which controls the two leading arc lighting systems in the city, has decided to abandon the direct system of arc lamps, and will introduce a new lamp supplied from transformers, with subterranean high tension conductors. These lamps will require renewals of carbon but once in three days, instead of daily. Meanwhile the streets of the city have been in comparative darkness at night. Fog and rain have prevailed, the holiday trade has added immensely to the local traffic, and the situation has been decidedly unpleasant for the public as well as the companies. The Brush Company had just expended 50,000 dols. for new wire, most of which is ruined, while customers have vainly offered 2 dols., or even 3 dols., per night for lamps for which they had previously paid but 50 cents. The unusual demand for gas lamps has exceeded the immediate supply, and they have been borrowed from neighbouring cities and transferred from unimportant districts.

The newspapers are just learning that although low tension currents may not be fatal to human life they may cause fires, and thus there is a probability that the general scare which has been so carefully nursed will finally react against the very interests which have advocated the suppression by law of high tension currents. As between the loss of life on one hand, and the loss by fire on the other, the electrical interests of the country will suffer tremendously, unless an immediate reform is begun, and every possible precaution taken to prevent these frequent accidents.

TESTS OF A TEN-LIGHT TRANSFORMER.

(From our New York Correspondent.)

PROFESSOR HARRIS J. RYAN, of Cornell University, read a paper, on December 17th, before the American Institute of Electrical Engineers, at New York, on "Transformers," in which a detailed description was given of the methods employed. It was illustrated with diagrams of the apparatus used. The transformer was operated under the same impressed electromotive force from the plant in which it had been supplying incandescent lamps commercially. It was tested with the secondary open, and also closed, through one, five, and ten lamps. The following are the data of the transformer used:—

Number of turns in the primary coil, 675; number of turns in the secondary coil, 35; resistance of the primary, 21·8 ohms; resistance of the secondary, ·04 ohms.

The iron discs of the magnetic circuit were one-half millimetre in thickness, the surfaces merely oxidised, so that no special insulating material was provided between the laminations. The total volume of laminated iron used was 2,050 cubic centimetres. The mean cross-section of the magnetic circuit was 63·3 square centimetres, and the mean length of the magnetic circuit 30·8 centimetres.

	Primary e.m.f.	Current.	Secondary e.m.f.	Mean of Ammeter Readings.
Observed $\sqrt{\text{mean}^2}$ with secondary on open circuit	1,025	·14	51·5	—
With secondary closed through one lamp	1,053	·196	52·3	1·26
With secondary closed through five lamps	1,050	·390	51·0	5·83
With secondary closed through ten lamps	1,040	·631	49·3	10·65

Curves plotted from the observations clearly showed the rate at which energy was given to the transformer, or that the transformer restored to the circuit at all points of a complete alternation for the several conditions under which it was operated. The following are the percentages of the work given to the transformer that is restored to the circuit by it under the foregoing conditions:—Open circuit, 6·8 per cent. One lamp, 3·9 per cent.; five lamps, 0·96 per cent.; ten lamps, 0·36 per cent. The above observations and data were sufficient for the computation of the various losses of energy that take place in the transformer under the several loads and under no load, and the deduction of the corresponding efficiencies as given in the following table:—

	*Secondary e.m.f. (Primary 1,020.)	Primary Watts.	Secondary Watts.	Efficiency per Cent.	Total loss in Watts.	Hysteresis Loss in Watts.	Heating Loss.	
							Primary Watts.	Secondary Watts.
Secondary open	52·3	96·1	0·0	0·0	96·1	95·7	0·4	0·0
One lamp	52·3	159·1	64·3	41·1	94·8	93·9	0·9	0·0
Five lamps.	50·1	388·6	300·9	77·5	87·7	83·1	3·3	1·3
Ten lamps.	47·5	607·9	525·0	86·6	82·9	69·7	8·7	4·5

It is interesting to note that this transformer might be loaded to twice its rated capacity, and the heating of the coils would still be less than that of the iron, although the heat produced by the iron grows less as the load comes on. Likewise that its efficiency would not yet have reached its maximum, and that it would have a value of 92 per cent. It was shown by the curves that the energy wasted by the eddy currents was small.

The assumption made by Mr. Swinburne, in his valuable paper on the "Design of Transformers," appears to have been fully substantiated. Mr. Mordey's experiments, in which hysteresis and Foucault current losses producing a common loss were determined, were performed by cycles of magnetisation produced by rotation in which the degree of magnetisation did not vary in amount, but direction, and cannot be said to throw light on the correctness of Mr. Swinburne's assumption. Commenting on this paper, some have used Mr. Mordey's results as evidence that these assumptions are wrong. By a knowledge of the magnetic properties of the iron with which a given transformer is to be built, and the methods made use of by Mr. Swinburne, its efficiency is something that can be correctly predetermined. The importance of making a transformer produce the same e.m.f. at the terminals of the secondary under all loads asserts itself when it is used for incandescent lighting. In the transformer under consideration the magnetisation produced through the secondary and the magnetisation set up about the primary in its own air space are determined. This leakage of magnetism amounted to about 1·2 per cent. When the transformer worked on full load 4·5 times as much current passed through the primary, and the leakage of the primary in its own space was 4·5 times as much as on open circuit, and became 5·4 per cent. This value, together with the small drop due to the actual resistances of the transformer coils, accounts for the fall of 3·5 volts that was observed by turning on all of the ten lamps. A similar leakage in magnetism takes place in the secondary circuit, producing a self-induction proportional to the secondary current. The rate of change of this quantity is then proportional to the e.m.f. that it produces. This e.m.f. is therefore a quarter of a period behind the secondary current, and results in producing a small lag in primary and secondary currents and secondary e.m.f. One peculiarity of this transformer remains to be explained; that is, the considerable decrease in the loss by hysteresis, as it is loaded down, that is not to be accounted for by rise of temperature or the falling off of the magnetisation due to the increased leakage about the primary in its own air space. Mr. Ryan made the following suggestion as to the reason for this:—Mechanical shock has been shown to greatly reduce loss by hysteresis when iron is passed through cycles of magnetisation. Since the currents are at all times opposite each other in the two coils of a transformer, strong repulsion occurs when these currents are at a maximum, and no force is exerted when they pass through zero. So it follows that they continually keep thrusting each other apart when at work, and add to the disturbance of the laminated iron that already exists on account of its changing magnetisation. This increasing of the mechanical vibration of the iron may, therefore, account for the above-mentioned phenomenon. On open circuit the maximum magnetisation of the iron per square centimetre was 3,850 c.g.s.; loss by hysteresis per cycle per cubic centimetre, neglecting Foucault currents, ·046 Joule at 138 per second, coercive force per centimetre of the iron 2·76 c.g.s. The conclusion of Mr. Ryan was that the data given show clearly the advisability of providing some practical means for breaking the primary circuit of the transformer when not in use, as insisted upon by Mr. Swinburne. The paper was discussed at length by Messrs. Kennelly, Tesla, Mailloux, Stillwell, Professor Geyer, and others.

* The values given in this column have not been corrected for the two lamps in series with the primary for the first three conditions, and the one lamp that was used for the last. With ten lamps, where one lamp was used in the primary, this correction amounts to an increase of the secondary e.m.f. of 3 per cent. On open circuit and one lamp it is negligeable, and 3 per cent. increase for five lamps. When this correction is applied, the drop of 3·5 volts obtained is what was observed by direct measurement on the secondary.

CELLULOSE AND ITS CONSTITUTION.

MESSRS. CROSS AND BEVAN have recently shown that the principal constituent of the jute fibre substance is a complex molecule, which yields, under different methods of attack, marcogallol, furfural, and acetic acid, thereby proving that the compound is one containing closed chains or rings of carbon atoms, and that its oxygen is of an aldehydic or ketonic nature. They have also further shown that the more inert cellulose, which constitutes the framework of the jute fibre cells as of other plant cells, is capable of forming, by the action of acetic anhydride in the presence of zinc chloride, an "acetate," which seems to be the penta-derivative, whence it appears that all the oxygen of cellulose behaves as hydroxyl oxygen, and that its molecule contains neither aldehydic nor ketonic oxygen. Hitherto the tri-acetate and tri-nitrate were the highest substitution products known. It is certain that this view of its constitution is conformable with the deductions to be drawn from the industrial aspects of the chemistry of cellulose, as shown by the sulphurous acid and bisulphite methods of isolating it, and the methods of the dyer and printer, which depend upon its weak combining affinities. The same authors have also published the results of their researches into the nature of the constituents of flax undertaken in connection with the introduction of a new system of linen bleaching into the Belfast district. The flax fibre contains in its commercial forms a large percentage (3–4) of constituents soluble in alcohol, which are associated with chlorophyll residues, and are separable into two main groups—(a) a resin wax containing the ceryl ether of cerotic acid; and (b) an oil wax which resolves into oily ketones. These constituents are obviously derived from the cuticular tissues of the plant, and play an important part in the wet spinning process peculiar to this fibre, the temperature of the water through which the roving passes preparatory to the drawing and twisting being such as to bring them into complete fusion. The removal of these wax constituents in the process of linen bleaching is the main source of the difficulties and complications of the process. These compounds are characterised by reducing a boiling neutral solution of silver nitrate, whereas pure flax cellulose does not affect this reagent. The non-cellulose constituent of the fibre substance—*i.e.*, the cast cell, free from cuticular and wood residues—yields pectic acids by alkaline hydrolysis and mucic acid on oxidation with nitric acid.

It is also interesting to note, in connection with the history of cellulose, that during the past year works have been established at Hartlepool for the manufacture of wood pulp by the sulphite process. This is practically a new industry in England, and it is proposed to import wood from Scandinavia and Russia for treatment in this country, and subsequent conversion into paper, instead of, as heretofore, allowing this industry to be a monopoly of the wood-growing countries.

Notes.

PATENT ABSTRACTS.

EVERYONE who wishes to keep his knowledge of electrical inventions up to date reads the *Electrical World* and the *Centralblatt für Elektrotechnik*. Some people cut out abstracts of any patents that seem good, and mount them under their subjects in a scrap book. May we suggest that the *Electrical World* would make it easier for its readers if it placed each illustration with its abstract, instead of one or two columns away from it?

THE EDINBURGH EXHIBITION.

WE hear that the French Government has recognised this Exhibition, and other countries will very likely do so too. Foreign exhibitors may apply for space till the 1st of February. For this country the date given is the 15th inst. The cost of buildings and grounds will be covered by the proceeds of refreshment contracts and concessions, so that the proceeds of admission go to cover working expenses. The Exhibition of 1886 began with £20,000 to the bad; that of 1890 looks very much more promising.

A UNIPOLAR DYNAMO.

OUR esteemed contemporary, *La Lumière Electrique*, describes a unipolar machine which gives enough electromotive force for incandescent lighting. From the description, we should have said offhand that the fallacy is obvious, and the machine would not work; but the output of an actual machine is given. The only thing to do is to apply David Hume's treatment for alleged miracles. Is it easier to believe the unipolar machine works, or that *La Lumière Electrique* is in this instance misinformed?

PRESENTATION TO MR. THOMAS PARKER.

ON the 21st ult., those employed by Messrs. Elwell-Parker & Co., or rather by the Electrical Construction Company, at Wolverhampton, presented Mr. T. Parker with a tea service and an illuminated address, as a token of their esteem. Few could be more deserving of the appreciation of his men than Mr. Parker. He is noted, not only for his extraordinary energy and "go," but for his carefully balanced knowledge of practical electrical engineering and business management. There seems to be much more kindly feeling between masters and men in the electric light trade than in others. This may be partly due to novelty, which leaves room for enthusiasm, but is also due to the masters themselves.

PROPOSED BRIDGE ACROSS THE BOSPHORUS.

THE most recent proposal for a huge bridge is for one across the Bosphorus, a project for which has been made out by a French engineering company. The historic and picturesque channel between the shores of Europe and Asia, which connects the sea of Marmora with the Euxine, is 872 yards broad, and it is proposed that the bridge to span it should be of one arch only. In these days of huge bridges this should not offer very serious difficulties from an engineering point of view, if the financial ones can be got over. Various projects have been put forward to the same effect during the past twenty years, but it was not considered that the bridge would be useful enough to justify the enormous expense which it would entail. Railways have, however, developed very much during recent years, and it is now thought that, if constructed, it would act as a link in the local railway system, and eventually pay a fair return on the money invested in it.

GLASGOW UNIVERSITY AND THE TECHNICAL COLLEGE.

AN important step has been taken towards making a closer connection between the University of Glasgow and the Glasgow and West of Scotland Technical College than has hitherto existed. The Senate of the University has resolved that the possession of a diploma of the Glasgow and West of Scotland Technical College shall be reckoned to the holder as equivalent to the first two years at the University for the degree of B.Sc. As this degree can be taken after three years' attendance at the University, it follows that those who hold the diploma of the Technical College may proceed to after one year's attendance at the University The diploma of the Technical College can be obtained by attending the day classes for three years, or completing the evening class course (which can be done during apprenticeship) and then taking one year at the day classes, so that, with a comparatively small exertion, those who wish to proceed to a degree will be able to do so. There are now four grades of study and examination. That for the junior certificate may be taken by all ordinary apprentices, while the senior certificate course may be taken by those who have had better opportunities or have greater abilities, and thus the diploma and the degree courses will allow some of the best students to pursue their studies as far as they please. The higher as well as the lower grades of those required in industrial works are thus provided for, and we consider that the former is even more important than the latter, for, as we have often pointed out, the men who will in the future create new industries or revolutionise old ones will be men who have received the most thorough training in the principles of science and in their applications to practical work.

THE COTTON TRADE.

THE following results of the quarterly stocktakings of joint-stock companies have just been announced, viz.:—

Mills.	Spindles.		Profit.
Albert	23,810	...	£578
Duke	70,380	...	1,360
Hathershaw	77,400	...	468
Ivy	34,600	...	437
Parkside	48,700	...	1,160
Royton	67,600	...	1,260
New Earth	44,000	...	470
Hope	66,700	...	900
Ridgefield	69,000	...	879
Hollinwood	75,000	...	1,052
Equitable	78,700	...	1,000
Stanley	48,400	...	104
Lees Union	63,000	...	250
Dowry	66,760	...	1,248
Rochdale	70,600	...	1,001
Staleybridge	75,400	...	1,245
Lees Brook	85,900	...	1,020

THE ACTION OF WATER ON WOOD AT HIGH TEMPERATURES.

TAUSS, in *Dingler's Journal*, has described some interesting experiments on the action of water on cellulose and wood at high temperatures. Cellulose, when boiled with water at ordinary pressures, yields traces of a sugar which reduces Fehling's solution and gives a red colour with phloroglucol. Pine wood behaves similarly, but gives a smaller quantity of sugar. Under 5 atmospheres pressure, cellulose, beech, and pine wood all give indications of the formation of sugar; and phloroglucol and hydrochloric acid give a violet coloration with the exhaust of the last two. Under 10 atmospheres phloroglucol gives the dextrose reaction distinctly with the cellulose extract, and beech and pine wood react similarly to the extract obtained at 5 atmospheres pressure. Under 20 atmospheres cellulose is completely changed into a jelly, which dries to a powder, and which appears to be a hydrocellulose $C_{12}H_{22}O_{11}$, burning red on the addition of phloroglucol. No vanillin was formed in any of experiments.

SAFETY APPARATUS FOR TRANSFORMERS.

MR. DRAKE has recently written to the *Standard* to point out that customers can be protected from danger by electrostatic cut-outs in the houses. Is it not very much safer to earth the middle of the secondary? It is better to remove a danger completely than to put some automatic arrangement to prevent its coming. Any automatic cut-out should be at the central station, where it can be looked after. Besides, the average customer already has a transformer, a pair of fuses, a meter, and probably a switch in his basement. He scarcely requires to have an extensive installation in his lower regions. Major Cardew's apparatus is not only very simple and ingenious, but it does not require an earth contact on its own account, which is a great advantage, but it is doubtful whether it is efficient. If it does not burn out both fuses, for instance, it is useless. Again, suppose an installation in perfect order. The primary electromotive force is 2,000 volts. If the installation is equally good on both sides, each main varies between + 1,100 and − 1,100 volts, the average potential of the system being zero. The average potential of all the secondaries will also be zero. Suppose some of the secondaries become earthed at one point each. There is nothing to show this, so no notice is taken of it. Suppose in one of these cases one primary lead now begins to leak to the secondary. That cut-out does not act, as the secondary is already earthed. If one of the other insulated transformers is cut off from its lamps, or if its lamp circuit has very little capacity, its cut-out may go, though there is nothing wrong there, for the potential of the primary system now varies from 0 to 2,200 volts, and will tend to bring the transformer secondary to 1,100 volts above the potential of the earth, and this will operate the cut-out. Moreover, if two or more houses have their secondaries partially earthed, and the different primary wires leaking to the secondaries, it depends on the resistances of the leaks whether a fire is caused or whether a cut-out goes. An automatic cut-out at the station also saves the main leads. If the primary system is earthed at the middle the maximum stress on the leads is 1,100 volts. If not, a minute leak on one side keeps the other lead under a stress of 2,200 volts. The same reasoning applies to earthing the secondary in the middle.

AN EXHIBITION AT JAMAICA.

THERE will be opened early in 1891, at Kingston, Jamaica, an Exhibition of island products and manufactures, and exhibits of machinery, &c., from Great Britain and elsewhere. The arrangements are being carried out by a commission, of which the Governor is the head, and a committee has been formed in London to co-operate with them. The chairman of the latter is Mr. C. Washington Eves, 1, Fen Court, E.C. No rent is payable by exhibitors, and no duties will be levied on goods not intended for sale. The attention of merchants and manufacturers in the United Kingdom is specially invited, and, as it is desired to show the advance of science in manufacturing tropical products, engineering firms are requested to give their aid by exhibiting plans, drawings, models, and specimens of actual machinery connected with such manufactures. As there is little doubt that one of the causes of complaints from the West Indies as to the unremunerative nature of sugar planting is due to the fact that in many cases the sugar making machinery is of an obsolete type, the opportunity may prove favourable for engineers in this line of business to find a market for their wares.

THE RECENT FLOODS IN JAPAN.

THE full accounts of the recent floods in Japan show some of the difficulties of carrying on engineering works in that country, especially those connected with roads and bridges, railways and telegraphs. Between April and September the country was visited by a succession of storms and floods almost without intermission. In Yezo many houses and cattle were destroyed, and other parts of the country were inundated, during the latter half of April. In June, frightful rainstorms took place along the west coast, and the rivers filled, while a strong westerly wind forced the sea up their mouths, so that the water spread all over the country and crops were ruined and houses destroyed to a very great extent. In July, in the island of Kiushiu, the Chikugo river overflowed its banks and wrought havoc in the Oita prefecture, about 4,000 acres of cultivated land being devastated, over twenty miles of embankments swept away; roads were rendered impassible, and business had to be suspended everywhere. In August, however, the floods were worse than all the others put together, and especially in South-Eastern Japan the calamity was great and widespread. In Kiushiu the Chikugo river again flooded a huge tract of country, the water rising 28½ft. above its usual level, and this it did twice in succession in three weeks. Thirty-three thousand three hundred and seventy-two houses were submerged, 2,741 bridges were swept away, 130 miles of embankment destroyed, and 73,694 persons were thrown on the world without adequate sustenance. In the south-eastern part of the main island 1,247 persons were killed or drowned. In September a terrible gale swept over Northern Japan, and the sea was forced over the embankments in various places along the coast and covered the surrounding country. The totals of the official returns, so far as they have been given in, are:—12 prefectures devastated, 2,419 persons killed, 155 wounded, over 90,000 deprived of the means of subsistence, over 50,000 houses swept away or submerged, 150,000 acres of crops destroyed, about 6,000 bridges washed away, and hundreds of miles of roads broken up. For thirty years no such calamity, or succession of calamities, has overtaken Japan.

APPLICATIONS FOR PATENTS.

(*The names in italics within parentheses are those of Communicators of Inventions.*)

ENGINEERING.

16th December, 1889.

20178. Carette & Platt..... Pulleys for cable-driving.
20180 Nenninger, R. F. ..... Smelting furnace.
20185. Rhodes & Lee ..... Friction brake.
20190. Britton, W. ..... Cutting machinery.
20191. Stubley, C. H..... Bolting machines.
20192. Hedderwick, P. ..... Collapsible boats.
20196. Barber, W. ..... Boot-making machine.
20198. Pocock & Johnson ..... Discharge and measurement of liquids.
20205. Jackson, W. ..... Sewing machines.
20215. Baillie, R. A. ..... Upsetting ends of metal bars.
20216. Resch & Grand ..... Sounding apparatus.
20220. Tower, B..... Maintaining a constant plane in a floating vessel.
20222. Trocmé, A. L. J..... Pile fabric looms.
20223. Taussig, E. ..... Casting.
20227. Lake, H. H. ..... Projectiles (*Wood*).
20229. Aunay, V. M. H..... Looms.
20230. Noble & Murray ..... Recoil presses.

17th December, 1889.

20245. Ireland, J. ..... Securing rails.
20249. Crist & Covert ..... Gas engines.
20252. Whiteley, B. ..... Ordnance and projectiles.
20256. Conlong & Horsfall... Looms.
20261. Gutensohn, A..... Annealing metal plates.
20265. List & Dick ..... Screw propellers.
20267. Berry & Gilbert ..... Steam pumps.
20271. Venables & Jones ..... Washing machines.
20272. Lake, H. H. ..... Railway wheels (*Cramer, Lindermuth, & Danstedter*).
20277. Melling, J. ..... Propelling tramcars.
20280. Cropper, Cropper, & Birks ..... Twist lace machinery.
20283. Browne, N. ..... Valves (*Vater*).
20287. Hansell, R. B..... Manufacture of springs.
20291. Schmidt, C. ..... Washing machines.
20293. Imray, H. ..... Breechloading firearm (*Sneider*).
20294. Imray, O. ..... Metallic fireproof structures (*Kensett*).
20297. Wise, W. L. ..... Quick-firing guns (*Von Skoda*).
20299. Liebing, B. ..... Rotating engine.
20300. Ricker, J. H..... Steam generators.
20305. Lake, H. H. ..... Separating machines (*Holt*).
20306. Amstetter, C. ..... Rotary motors.
20308. Boult, A. J. ..... Sewing machines (*Von Pittler*).
20310. Boult, A. J. ..... Steam engines (*Stanwood*).
20320. Neave, W. A. ..... Machine for grading wheat.

18th December, 1889.

20321. Green, E. C..... Revolvers.
20325. Clegg, J. ..... Mules.
20327. Ingham & Ingham ..... Looms.
20330. Barnes, H..... Warp beaming machines.
20333. Lewinsohn, H..... Printing machines.
20340. Irvine, J. D'A..... Projectiles.
20342. Wright & Gillott..... Flooring for bridges.
20343. Spiers, J. ..... Welding tubes.
20346. Matthews, A. ..... Coupling for railway carriages.
20353. Meldrum & Meldrum Furnaces.
20355. Stensland, C. ..... Regulating speed of propellers.
20361. Paul, A..... Railway brake.
20365. Duesberg-Bosson, H.... Carding textile materials.
20368. Wise, W. L. ..... Coke ovens (*Semet*).
20375. Kitt, A. ..... Apparatus for transferring coal.
20376. Cutlan, J..... Sewing machine.
20380. Bott, J. E..... Compound armour plates.
20386. Pilard, A. J..... Spinning wool.
20389. Kenoyer, B. ..... Propelling boats.
20395. Brady, Powers, Quinn, & Maher..... Casting ingots.
20398. Cawston & Scott ..... Screw propellers.
20405. Liardet, J. E. ..... Utilising tidal power.

19th December, 1889.

20415. Avery, W. B. ..... Weighing apparatus.
20416. Critchley & Lancaster Looms.
20422. Walton, W..... Grinding card clothing.
20423. Walton, W..... Wiredrawers' benches.
20425. Drury, R. F..... Animal clipping machines.
20430. Harris, H..... Machine for manufacturing ropes.
20435. Watson, T. ..... Spinning frames.
20439. Edward, G. ..... Punching and shearing machines.
20441. Sivewright, G. W..... Anchors.
20442. Betham & Woolnough Disengaging ships' boats.
20443. Wallis, A. H. ..... Compound engines.
20444. Wells, C. ..... Furnaces.
20445. Smith, J. W..... Washing machinery (*Robbie*).
20453. Boult, A. J. ..... Magazine firearms (*Luigi & Peraldi*).
20455. Decollogne, E. ..... Automatic distributors.
20456. Bracher, P. H..... Screening apparatus.
20459. Barnes, D. L. ..... Railway car frames. (21st May, 1889.)

20th December, 1889.

20462. Fletcher, J. M. ..... Projectile.
20467. Tattersall, W. ..... Air propellers.
20470. Campbell, J..... Drying kilns.
20475. Dougill, J. ..... Gas engines.
20476. Dunlop, M. ..... Stuffing boxes.
20477. Wilkinson, R. ..... Looms.
20482. Atkinson, J..... Heat engines.
20498. Grant, T. B..... Steam boilers.
20500. Blackburn & Davenport ..... Coupling waggons.
20507. Matthews & Laidman Framing and plating ships.
20512. Clark, A. M..... Throttle valves (*Barclay*).
20514. Davies, E. ..... Projectiles.
20519. Geiersbach, F..... Automatic brakes.
20522. Brasseur, V. ..... Valve gear.
20525. Clay, C. ..... Horse rakes.

21st December, 1889.

20527. Sharp, J. W..... Machinery for manufacture of boots.
20529. Gallon & Chapman ... Hydraulic valves.
20530. Tervet & Reid..... Filter presses.
20537. Clarke & Clarke ..... Glove machinery.
20540. Warren, F. P..... Internal casing of iron ships.
20543. England & Hughes ... Milling machines.
20545. Robson, J. M. ..... Stuffing boxes.
20549. Garstang & Bancroft Warping machines.
20550. Newall, G. W. ..... Valves for engines.
20551. West, J..... Machinery for charging gas retorts.
20566. Wallis & Longden ... Lace machines.
20567. Wakefield, C. C. ..... Sight feed lubricators. (10th September, 1889.)
20570. Fisher & Russell ..... Level crossing gates of railways.
20576. MacIlwraith, W. ..... Open shed jacquard.
20579. Crow, S..... Wringing machinery.
20581. Barre, C. A. A. ..... Sliding railways operated by hydraulic propulsion.
20585. Tafel, P. A..... Bolting apparatus.
20586. Darby, J. H..... Manufacture of steel.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Looms.—*I. Hillas, Morley, Yorkshire.*—The object of this invention is to save the wear and tear of neck bands in double lift harness, and to use one only where hitherto two have been employed. Use is made of a sliding metallic double loop or union, through which pass the two upright or vertical wires or rods connected to the lifting motion of the dobby. A hook or link is preferably attached to the centre of each double loop. This hook carries one neck band, which as usual carries the leashes or heads attached to the healds. When the dobby lifts one of the vertical wires the loop slides up the other and takes the neck band with it. Claims: (1) Connecting the two upright or vertical wires in any manner so that half the number of neck bands are dispensed with; (2) the combination of the vertical wires and double loop with or without the link.—No. 8326. May 20th, 1889. 6*d*.

Slide Valves.—*W. J. Thompson, Liverpool. (H. D. Haverkamp, Derember, Holland).*—The slide valve is constructed so as to reduce the "port clearances" of the engine cylinder. The port surfaces are step-like in form. The part surrounding the exhaust ports is raised to permit the coring out of the exhaust passage as usual. The inlet ports are reduced at each end so as to make the "port clearance" as small as possible. Two slides are employed, one at each end of the cylinder, and they are connected to one rod, which is worked in the usual manner. Each valve has two working faces, one for the inlet port and the other for the exhaust. Claim: A slide valve for steam engines, in which the face or faces adapted to control the admission of steam are placed in a different plane from those adapted to control the exhaust.—No. 16666. October 22nd, 1889. 6*d*.

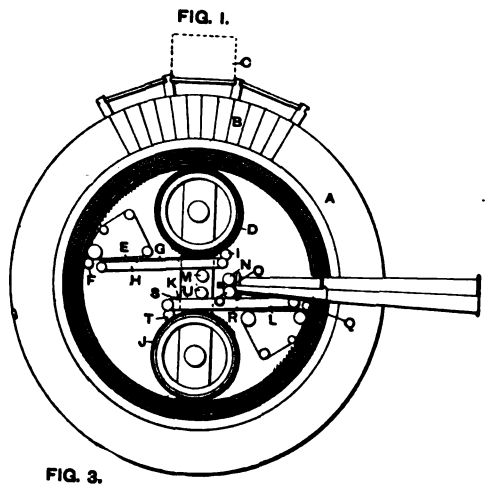
Stone Breaking Machinery.—*A. Hill, Leicester.*—This invention relates to stone breakers, in which the motion of the jaw is obtained direct from the eccentric shaft. The weight of the jaw upon the eccentric shaft causes undue friction and wear, which is here obviated by the following means. On the front of the rocking lever is fixed a nose piece A, which enters a recess

B in the swing jaw. To the nose piece A is attached the rod C, which is pulled upwards by the springs D upon the support E. By this means a self-lifting motion is given to the swinging jaw. Claim: The self-lifting motion to the stock or swing jaw, by the novel mode of coupling the toggles—nose piece, or rocking lever—to the top of frame or brackets in the manner mentioned.—No. 666. January 14th, 1889. 6*d*.

Covers for Drain Openings, &c.—*J. Jones, London.*—An improved form of cover is here described for man-holes and similar openings of drains to prevent the passage of vapours from them. The frame of the man-hole is constructed with a small channel round the inner side of its lower edge. Into this channel the edge of a dome-shaped plate rests, the dome-shaped plate being either separate or connected to the under part of the flat surface plate. As the vapour rises from the drain it comes into contact with the cold surface of the dome plate and condenses, running down its sloping sides to the channel, and ultimately forming a water seal. Claims: (1) In a man-hole, or similar cover, the utilisation of the liquid formed by condensation on the man-hole cover for automatically making a gas-tight seal around its edges; (2) in a man-hole, or similar cover, the combination with a frame provided a channel of a domed or similar plate, the edges of which rest in or enter the said channel for the purpose described,—No. 16455. October 18th, 1889. 6*d*.

Wool-combing Machines.—*D. P. Norris, Methuen, U.S.A.*—The improvements are made in combing machines of the Noble class. The large and small circular combs and carrying aprons are combined with guides, which take the sliver from the aprons and deliver them directly to the delivery tube. The delivery tube is shaped to compress the sliver and deliver it clear of the

FIG. 1.



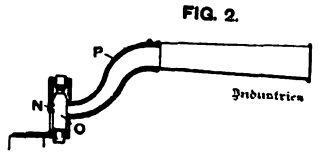


FIG. 3.

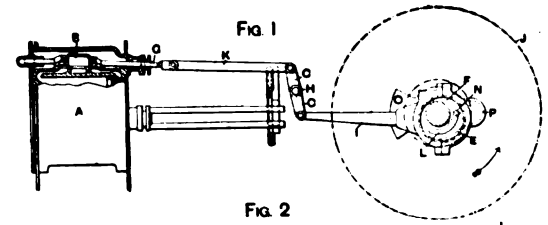
FIG. 2.

machine. In the drawings Fig. 1 is a plan of a portion of a wool-combing machine, showing part of the delivery tube in section. Fig. 2 is a vertical section upon the side elevation of the delivery tube and co-operating devices. A is the arge circular combs; J, D the smaller ones; E and L are endless aprons, which take the sliver off the large comb; I T are the rolls for taking the sliver off the small combs. The sliver is taken off the large comb and conveyed by the aprons H S to the points where the sliver is taken off the small combs; here it combines, and is carried forward by the rolls M U. The sliver from the two different sets of aprons unite upon the roller U, and are then passed into the bite of the calender rolls O N, Fig. 2, which compress and feed them to the delivery tube. The delivery tube is bent to carry the fibre clear of the machine and slightly compress it before delivery. Claims: (1) The combination of the large and small combs and drawing off rolls and aprons of a wool-combing machine, with a single delivery tube, having its receiving ends substantially at the level of the aprons, and guides, by which the fibre from the aprons taken from all the combs is directed without twist into the said tube, substantially as described; (2) the combination of the large and small combs and drawing off rolls and aprons of a wool-combing machine, with a single stationary guide tube, into which the united fibre from both aprons is carried, and calender rolls and a delivery tube having its mouth opposite the said guide tube, into which delivery tube the sliver is carried from the guide tube by the calender rolls, substantially as described; (3) the combination of the large and small combs and drawing off rolls and aprons with a single delivery tube that receives the united sliver from both aprons and has its receiving end at the level of said combs, and is curved upward and extends laterally to its delivery end, which is at a higher level than its receiving end substantially as and for the purpose described; (4) the combination of the large and small combs and drawing off rolls and aprons of a wool-combing machine, with a stationary delivery tube having its receiving end substantially at the level of the aprons and adjustable binders, by which the fibre from the aprons is directed into the said tube, substantially as described; (5) the combination of the large and small combs and drawing off rolls and aprons of a wool-combing machine, with a delivery tube having its receiving end near enough to said aprons to admit of the combined sliver from said large and small combs being carried from the aprons to the delivery tube without twist, substantially as described.—No. 14681. September 17th, 1889. 8*d*.

Compound Locomotives.—*F. W. Webb, Crewe.*—An improvement is here introduced in the reversing gear of a class of compound locomotive engines, for which the inventor was granted a patent, No. 1128 of 1881. The compound locomotives are of that class in which the wheels driven by the high pressure cylinders are uncoupled from those driven by the low pressure cylinder or cylinders, and the improvement consists in using an automatic

FIG. 1



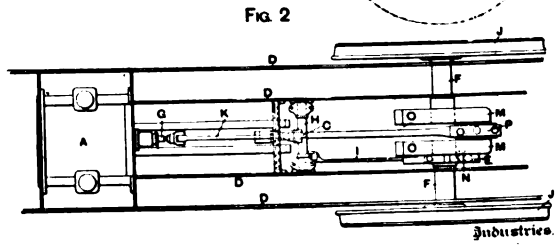


FIG. 2

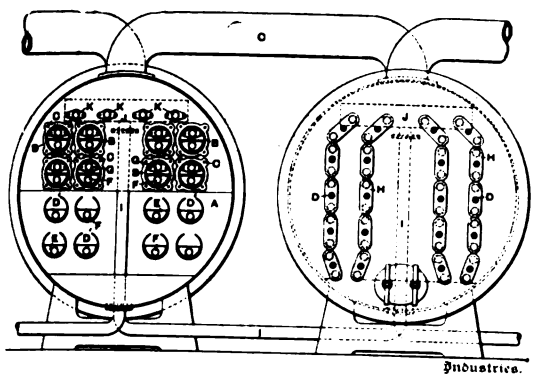
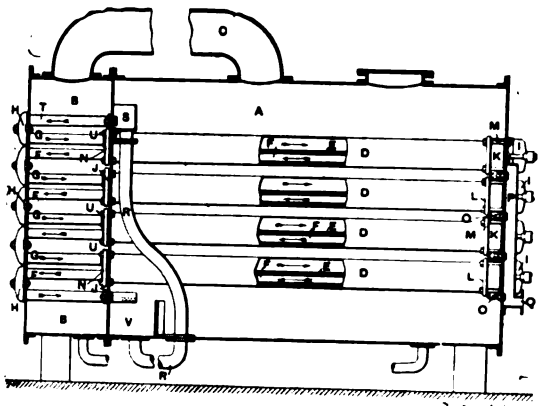


reversible valve gear, such as a single eccentric, which can rotate to a certain extent on the driven axle, and thus change its position automatically. The illustrations give a side elevation and plan of an engine cylinder and valve with the automatic reversible gear. B is the slide valve of the cylinder A, connected to the rocking lever C, which is worked by the eccentric E. The eccentric is loose upon the shaft F, yet made to revolve with it by a pin N in the slot L. When the engine is started, and the wheels J rotate in the direction of the arrow, the pin N will come against one end of the slot and carry the eccentric round with it in the right position for that direction. If the engine be now reversed the pin will come against the other end of the slot, and carry the eccentric in the right position for the direction it now travels. Claims: (1) In compound locomotives, where a pair of cylinders drive one axle, and a single cylinder, or pair of low pressure cylinders, drive another axle, uncoupled with the axle driven by the other pair of cylinders, the combination therewith of automatic reversing gear for the valve or valves of the low pressure cylinder or cylinders; (2) the combination and arrangement of automatic reversing gear for the valve or valves of the low pressure cylinder or cylinders of compound locomotive engines, acting independently of the high pressure cylinders.—No. 701. January 14th, 1889. 8*d*.

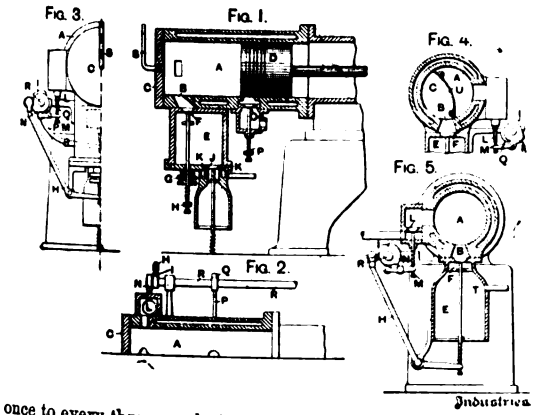
Evaporating Apparatus.—*T. Slaiter, London.*—The inventor introduces an improved construction of the apparatus described in a previous patent, No. 10493 of 1888. In the apparatus the liquid is evaporated and concentrated by flowing over open trays or gutters, which are heated by steam, and contained in a vacuum chamber. In the illustrations Fig. 1 is an end elevation of two chambers arranged in series, one being partly in section, and Fig. 2 is a longitudinal section of the chamber. In the figures A is the vacuum or evaporating chamber, B a steam or vapour chamber at one end, C the exhaust pipe connecting the vacuum or evaporating chamber of one vessel with the steam or vapour chamber of the next vessel or to an air pump, D removable evaporating tubes containing the gutters E for conveying the heating steam, and F pipes for the circulation of concentrating water. G are short pipes forming continuations of the trays through the steam chambers, and connected by the elbows H to the return pipes F. I are closing caps at the other end of the tube. The steam chamber ends of the tubes D are closed except to the pipes G. The first vessel receives its steam from the exhaust of the air pump engine. The second vessel derives its heat from the vapour arising from the fluids in course of concentration in the

Digitized by Google



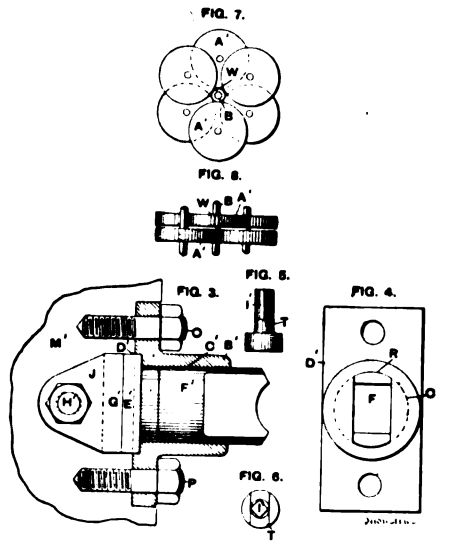
first vessel; the third from the second, and so on. The fluid to be evaporated is drawn through a pipe R into a box or tank S; from here the fluid passes through pipes T to the pipes G, which lead to the trays of the uppermost tubes D. After passing along these trays it returns by the return pipes F, and from them descends to the next layer of trays, and so on. Claims:

FIG. 1.



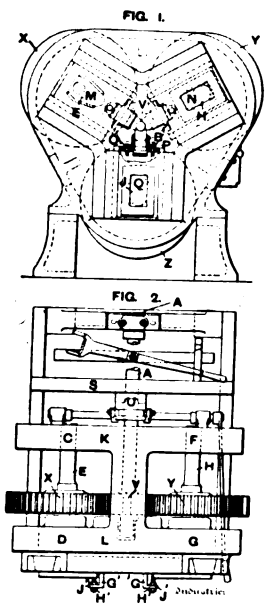
(1) The combination of the vacuum chamber, the readily removable tubes passing through both ends thereof, each tube having a tray or gutter within and across it, and open at the top where it is within the vacuum chamber, and means for supplying the tubes below the trays or gutters with steam or heated fluid, and for passing liquid to be evaporated over the surface of the trays

FIG. 2.



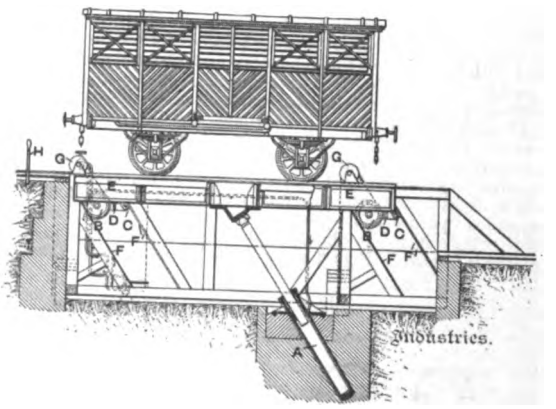
or gutters; (2) the combination of the vacuum chamber, the steam chamber at one end thereof, the readily removable tubes passing through both ends of the vacuum chamber, each tube having a tray or gutter within and across it, and open at the top where it is within the vacuum chamber—the return pipes passing back through the steam spaces below the gutters and through the steam chamber, and means for leading the liquid under concentration over the upper trays or gutters, then through the return pipes below them, and on to the trays or gutters below them, and so on; (3) the construction of evaporating apparatus substantially as described.—No. 34. January 1st, 1889. 11*d*.

Gas Engines.—*J. Roots, London.*—The inventor describes a method of obtaining double expansion of the gaseous charge. Fig. 1 is a side elevation; Fig. 2 a half sectional plan; Fig. 3 a half end elevation of the engine; Fig. 4 shows a modification; Fig. 5 shows a one-to-two arrangement giving the double expansion. A is the cylinder, D the piston, E a chamber for receiving half the charge, H is a lever which opens or raises the valve F by means of the cam I. J is the inlet valve to the chamber, which also covers the gas orifices K. L is the first exhaust valve opened by the lever M and cam N. O is the second exhaust valve opened by the lever P and cam Q. The exhaust valve shaft R is revolved

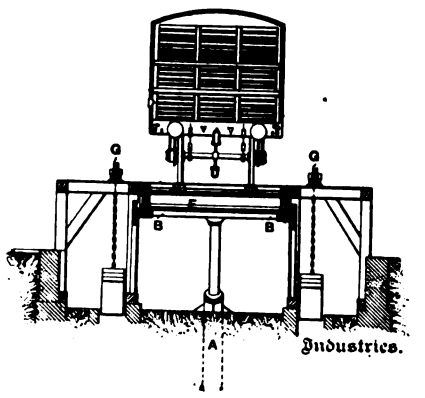


once to every three revolutions of the crank shaft. S is the usual igniting pipe kept at a red heat. At the commencement of the compression instroke the valve J closes, the valve F being kept open by the cam during a part of the instroke; a portion of the charge is returned to and compressed into the chamber E, as well as in the cylinder and clearance space. When the valve F is closed the half charge in the cylinder is further compressed and exploded doing a full working stroke. The chamber E has about half the cubic space of the whole piston stroke. Close to the working stroke end, the exhaust valve O is opened and a part of the exhaust let out. Near the dead point the valve F opens by its cam or by the pressure of the charge in the chamber E, and the half charge then pours into the cylinder, displacing more of the exhaust during the instroke until the piston has covered the exhaust valve O. During the remainder of the instroke the second half charge is compressed together with the remaining products, and fired, performing the second working stroke with double expansion. At the end of the second stroke the first exhaust valve L is opened by its cam, and the cylinder is completely exhausted on the instroke. Claims: (1) The combination and arrangement of mechanism whereby the cylinder inlet valve placed between the cylinder and the chamber E is retained open during about half the instroke following the suction outstroke, so that about half the charge only is fired at each time, thus allowing it double the expansion; (2) the chamber E for receiving about half the charge drawn in the cylinder during the suction stroke, and this portion of the charge being compressed in the chamber E assists in displacing the exhaust products in the cylinder; (3) the method of working with two working strokes in three revolutions, each allowing double expansion; (4) the combination and arrangement of mechanism for producing two working strokes in three revolutions; (5) the modified arrangement, as described with reference to Fig. 4; (6) the chamber E open to the air for receiving uncompressed the portion of the charge displaced by the piston on its instroke, there being a working stroke every other revolution; (7) the method of working and arrangement of parts, as described and shown in Fig. 5.—No. 16220. November 9th, 1888. 8*d*.

Power Presses.—*J. S. Taylor & S. W. Challen, Birmingham.*—The press is constructed to operate upon such objects as cartridge shells. The improvements enable pressure to be given in different places at the same time, and a complete circle of pressure can, if so desired, be given by means of the different tools attached to the press. In the illustrations Fig. 1 is a front elevation of the press, Fig. 2 a plan, and Figs. 3, 4, 5, 6, 7, and 8 details.



Instead of, as in the ordinary press, the tools operating in one plane and in one direction, a number of tools are arranged radially about a given centre to work in different directions. In the apparatus illustrated three tool holders B^1, C, and P are shown arranged radially to the centre V. The tool holders are fixed to the ends of suitable slides in the frame of the machine, and are actuated by eccentrics upon the three shafts E, H, and J. A central shaft A drives the three shafts E, H, and J by suitable gear wheels, and is itself driven from pulleys upon one end. A suitable fly wheel S and clutch arrangement U are also applied to the shaft A. Figs 3 and 4 give an enlarged view of the tool holder B^1. A central circular hole C^1 has a rectangular space D^1 formed at the base, and a slotted hole R at the front. Within the hole C^1 is a



cap E^1, which serves to hold the tool in position. The tool is also shaped to fit the oblong hole in front of the holder. The tool is adjusted by a wedge G^1, whose bent head receives a screw H^1 for the purpose of shifting the wedge. Figs. 7 and 8 show the arrangement for driving a number of radial slides by means of a long pinion W working in sets of toothed wheels. Claims: (1) The combination of a central shaft with pinion driving three other shafts by means of toothed wheels, which shafts actuate radial slides carrying dies for the purpose of compressing copper bands on steel projectiles; (2) the combination and arrangement of a press or machine, whereby radial punches or tools are caused to operate upon an object simultaneously; (3) the construction of a tool holder with an adjusting sliding wedge and block; (4) the combination of sets of toothed wheels placed one set behind the other, driven from a single long pinion, or a number of shorter pinions, upon a central shaft, whereby a number of radial slides are simultaneously operated from shafts rotated by the toothed wheels.—No. 14,261. September 10th, 1889. 6*d*.

Hydraulic Lifts.—*A. A. Vingner, Paris.*—The principal novelty of this lift is in the raising of the platform in an inclined instead of vertical direction. The weight of the platform and of the load is carried by the hydraulic cylinder and four wheels which travel upon inclined guides and are fixed to the corners of

the platform. When the centre of specific gravity of the load is not central upon the platform unequal weights are thrown upon the pulleys, but no stress is made upon the platform, which remains horizontal. In the illustrations, A is the hydraulic ram constructed to work upon the centre of the platform E, B are

the wheels working upon the guides F. The weight of the platform E is counterbalanced by weights attached to chains passing over the pulleys G. Spring slides C work upon the guides F^1 to prevent the platform lifting at one end when the load is not central. Claims: (1) The improved construction of lift or hoist, wherein a horizontal platform is moved in an inclined direction by means of one or more inclined hydraulic cylinders or equivalent appliances, the platform being guided in its motion by means of inclined guide rails arranged parallel to the hydraulic cylinder, against which rails the platform is made to bear either by means of wheels or slides, or both combined; (2) the construction of hydraulic lift or hoist with platform travelling in an inclined direction arranged and operating as described.—No. 198. January 4th, 1889. 8*d*.

Boiler Furnaces.—*E. Dobson, Jarrow-on-Tyne.*—The object of this invention is to encourage the consumption of the smoke, and to utilise the increased heat evolved without diminishing the draught of the fire. The inventor places at the rear of the bridge, and preferably on the same level as the dead place, an air chamber the width of the furnace; into this chamber air is admitted from the ash pit through an opening at the under side of the chamber, the admission of the air being regulated or cut off by means of a valve or damper operated by any suitable means, such as by a rod carried to the front of the furnace. From this chamber the air passes by a large number of small openings in the top of the chamber. This top plate is preferably inclined, the inclination being downwards from the back of the bridge. Through the bridge over the dead plate passages are made coinciding with openings in the front of the air chamber, so that hot gases from the fuel can enter into the air chamber. By the foregoing means hot air passes from the ash pit into the air chamber, and passes therefrom through the perforations in the top, and so is brought in a number of small streams into contact with the smoke directly they have passed over the bridge. Claims: (1) In steam boiler and other furnaces an air chamber, situated close behind the fire bridge and communicating at the bottom with the ash pit, and having the top perforated with a great number of small holes, through which heated air passes from the interior of the chamber to mingle with the products of combustion passing over the bridge; (2) in steam boiler and other furnaces an air chamber, situated close behind the fire bridge and communicating with the ash pit, the top and one side of the chamber being perforated, the perforations in the side coinciding with perforations or passages in the fire bridge; (3) the combination with the subject matter of either of the preceding claiming clauses of means substantially as hereinbefore described for automatically admitting air from the ash pit to the flue behind the fire bridge when the furnace door is being closed, and for gradually cutting off the supply of air after the furnace door is closed; (4) the general combination and arrangement of parts constituting means for effecting the burning or consumption of smoke in furnaces.—No. 19057. December 31st, 1888. 8*d*.

STEAM ENGINES.—*E. P. de Soveral, London.*—The object of this invention is to lessen the friction of the slides of piston rods by substituting for the sliding faces rollers or wheels which can be arranged to work in the existing guides of steam engines. To prevent lateral shifting of such rollers, they may have flanges on their periphery to project over the sides of the guides, or they may be made to work in grooves in the guides. The body of the crosshead may have several rollers attached to take the bearing on the guides, or one large wheel may be used. Four claims are made.—No. 6680. April 18th, 1889. 8*d.*

CHEMISTRY.

PRODUCTION OF COMBUSTIBLE GASES.—*B. H. Thwaite, Liverpool.*—In this improved method use is made of the ordinary coal gas retorts, the mode of proceeding being as follows:—A retort is filled with broken pieces of refractory material, and connected to a second in which is distilled carbonaceous fuel. Both are heated to a high temperature, and the hydrocarbons evolved from the second retort passed by the connection through the first retort, and from there to the hydraulic main. After the evolution of all the hydrocarbons, steam is passed through the first retort filled with the refractory material, which has collected suspended pieces of solid hydrocarbons in the previous action, and scours it of these suspended hydrocarbon. The steam is then passed to the second retort, where it meets the incandescent fuel and becomes dissociated into gases. Figs. 1 and 2 show the method of connecting

FIG. 1. FIG. 2.

the retorts, Fig. 1 being a back view of the retort, and Fig. 2 a front view. In Fig. 1, A, A^1, A^2 are the retorts; B, B^1, B^2 the valves by which the connections are made. In Fig. 2, C, C^1, C^2 are valves in the ascension pipe, and E, F, and G are tanks, pipes, and valves for admitting into the retorts, &c., tar, naphtha, or other hydrocarbon for the purpose of enriching the gases. Claims: (1) The cycle of operations producing combustible gases as applied to gas retorts of the ordinary kind; (2) the arrangements for connecting the retorts to each other and the gas and steam valves connected therewith; (3) the arrangement of converting one retort into a superheater in connection with a second or third coal or cannel charged retort; (4) the arrangements for simultaneously effecting the reversal of the steam and gas valves.—No. 16970. November 22nd, 1888. 8*d.*

RECTIFYING ALCOHOL.—*A. de Meritens, Paris.*—The present invention has reference to Patent No. 13293 of 1888, according to which an alternating current of electricity is employed in treating and rectifying or aging alcohols. An alternating current is essentially a current causing combinations, whilst a continuous current is a current causing dissociations. The object of the present invention is to provide substances capable of combining immediately with the aldehydes under the action of an alternating electric current, and of forming stable combinations indestructible by heat even at temperatures as high as 100° C. The substances which give the best results are ammonia, aniline, the phenylene-diamines, such as meta-phenylene-diamine, and their salts. These substances are capable of combining directly with the aldehydes when brought in contact therewith at temperatures from about 80° to 100° C. Under the action of an alternating current the combination takes place without any perceptible rise in the temperature, and as this combination cannot be destroyed by heating even to about 100° C. the employment of the above mentioned substances enables the process to be conducted under most favourable conditions. To the impure alcohol to be treated with an alternate current the inventor adds two equivalents, for example, of ammonia or aniline, or of a salt of meta-phenylene-diamine to one equivalent of aldehyde. Claim: In the treatment or rectification or aging of alcohol or alcoholic liquors and the like by electrical action the employment of substances such as ammonia or aniline or phenylene-diamines or their salts.—No. 16,947. October 26th, 1888. 4*d.*

COLOURING MATTERS.—*C. D. Abel, London.* (*Actiengesellschaft für Anilinfabrikation, Berlin*).—The inventors have discovered a new set of colouring matters which are prepared by acting on the sulphurated bases which are formed by heating m-xylidine or pseudo-cumidine with sulphur by nitrous acid and then mixing the diazo products thus formed with phenol, &c. Claims: (1) For the manufacture of dyestuffs, the production of sulphurated bases by heating m-xylidine or pseudo-cumidine with sulphur; (2) the production of azo dyestuffs from the sulphurated bases mentioned in the first claim by the reaction of nitrous acid upon the sulphurated bases and by the combination of the diazo compounds thus obtained with phenol, its homologues, resorcine, resorcine ethers, orcine naphthol, dioxynaphthalene, phenylene-diamine, toluylen-diamine, chrysoidines, Bismarck-Brown naphthylamine and its alkyle derivates, or with their sulphonic or carbonic acids; (3) for the production of azo dyestuffs the conversion of the sulphurated bases mentioned in the first claim into their sulphonic acids, the reaction of nitrous acid upon these acids, and the combination of the diazo compounds thus obtained with the substances mentioned in the second claim; (4) as a new manufacture the orange, yellow, brown, and red dyestuffs produced as described.—No. 17333. November 28th, 1888. 6*d.*

WHITE LEAD.—*H. B. Condy, London.*—The inventor describes a method of producing white lead from lead by first generating acetate of lead, and then converting it into the carbonate. Metallic lead is carefully granulated by melting and pouring it into water, and a vat is filled. Above the level of the vat is another vat in which dilute acetic acid is placed, the proportion being about 55lb. of acetic acid, containing 40 per cent. of hydrated acetic acid, to about 625lb. of water. This vat is connected to the former vat by pipes provided with cocks so that the liquor may be run on to the metallic lead and turned on and off at will. After allowing the acid to run on to the lead and remain in contact with it for a period of from four to six hours, the liquor is run off into a vat placed at a lower level, so that the lead is left exposed to the atmospheric air and oxidised. The liquor which has run through the lead is pumped up into another vat above the level of the lead, and after the lead has become sufficiently oxidised the same liquor is again run on to the lead and the coating of oxide is dissolved and removed. This operation of alternate oxidisation of the lead by atmospheric air and solution of the oxidised lead is repeated until the specific gravity of the liquor reaches 1·145 or thereabouts. At this stage the liquor is pumped into a closed tank, fitted with an agitator. Carbonic acid gas is driven into this vat until it is found that the contents have become neutral; at this stage the white lead must be separated from the liquor in which it has been precipitated. The liquor thus separated is again treated with carbonic acid until it appears, upon testing a small sample drawn from the bulk, to give no further precipitate, or only a slight cloudiness with further treatment by carbonic acid.—No. 18705. December 21st, 1888. 6*d.*

EXTRACTION OF GOLD.—*M. H. Simpson, London.*—This invention relates more especially to the extraction of gold by the wet processes, from such auriferous materials as pyrites, or tailings, obtained in the ordinary gold washing processes. In such processes the use of bromine is very effective, but the difficulty of safely conveying and keeping the bromine in a liquid form is an objection. This invention has for its object a novel method of preparing and treating bromine so that it is obtained in a form easily transported and stored. The inventor takes a strong solution of a caustic base such as caustic soda, potash, or ammonia, or the carbonates of these bases, or employs the oxide, hydrate, or carbonate of any other suitable base, and saturates it with bromine, thereby forming a hypobromate or a mixture of bromide and bromate of the base. The solution is evaporated to dryness, and a dry powdery material is obtained, capable of being carried or transported in boxes or barrels or other suitable vessels. Of the several bases capable of being employed in the way described, the caustic soda is preferable. In order to obtain the bromine from this salt or mixture of salts, all that is required is to dissolve the material in water and add to the solution an acid such as sulphuric acid, when the bromine is at once set free. The soda-bromine material is easy of transport and without danger, unlike liquid bromine, whilst from it liquid bromine may be obtained at any time as already described. In order to obtain an acid material likewise easy of transport for the purpose of liberating the bromine from the soda-bromine material, the inventor takes sodic or potassic sulphate, and treats it with sufficient sulphuric acid to form an acid sulphate, heating the mixture to expel all water. The mass is allowed to cool, when it solidifies and may be broken up and packed in suitable boxes or barrels. When the bromine is to be used for the extraction of gold, the auriferous material to be treated is placed in barrels or other suitable vessels capable of being hermetically sealed, and is then moistened with the requisite amount of a solution of the soda-bromine compound described. A solution of the acid sulphate is next added in quantity sufficient to liberate the bromine, and the containing vessel is closed and agitated occasionally for a few hours. The auriferous material is then washed, and any excess of bromine present volatised and condensed, and the solution containing the gold subjected to any known method for the precipitation of the gold. Claims: (1) The method of combining bromine with caustic bases, or with the carbonate of such bases, or with the oxide, hydrate, or carbonate of other suitable bases, evaporating the mixture to dryness, so as to obtain a material containing bromine capable of being readily transported, and from which the bromine can be set free when required; (2) in order to set free the bromine from such salt, or mixture of salts, when required, the addition of an acid such as sulphuric acid; (3) in order to obtain an acid material, in a convenient form for carriage, for the purpose described, the treatment of sodic or potassic sulphate with sulphuric acid to form an acid sulphate, heating the mixture to expel all water, allowing the mass to cool and solidify, and breaking it up into pieces convenient for packing; (4) the addition to the bromine compound of a suitable carbonate in order to obtain pressure in the vessel in which the bromine is used for the extraction of gold.—No. 17930. December 7th, 1888. 6*d.*

MISCELLANEOUS.

OBTAINING MOTIVE POWER FROM TIDAL WATERS.—*C. Hussmant & I. Dramant, Melbourne.*—The method consists in the employment of two large suitably constructed reservoirs adapted to be filled and emptied alternately by the rise and fall of the tide. Each reservoir is connected with one or several turbines in any convenient manner, and these turbines are arranged to be operated by the water passing in and out of the reservoirs. The system is worked preferably as follows:—Assuming the total rise and fall of the tide to be twenty-four feet, and that one of the reservoirs is full whilst the other is empty, then as soon as the tide has fallen a certain extent, say eight feet, the turbine connected with the full reservoir is set to work by allowing the water to pass through it to the sea until the tide by its again rising reaches the height of the water in the reservoir, say at sixteen feet. The turbine connected to the empty reservoir is inoperative until the tide has reached a height of about eight feet above low water, when the water is allowed to flow in past the turbine until the level of the water in this reservoir is equal to that of the sea by its again falling. Effective power is thus obtained from each reservoir for about seven and a half hours in each tide, thus giving fifteen hours effective working per day for each turbine. Claim: The improved method for obtaining motive power from the action of the tides, said method consisting essentially in allowing water to flow into and out of a pair of reservoirs, through a water motor or motors in such a manner as to obtain a source of continuous power.—No. 12454. August 6th, 1889. 8*d.*

REGENERATIVE GAS LAMPS.—*L. Somzée, Brussels.*—This improved regenerative lamp is designed to stand a higher temperature than those of other systems, and consequently give a better light. Fig. 1 is a sectional view of the lamp; Fig. 2 a plan view of the top of the regenerator; and Fig. 3 an elevation of the regenerator. The lamp comprises heater M with walls I, on which the products of combustion play before passing to the chimney. The heater terminates below in a cylindrical pipe D^1. On the lower end of the heater is an enamelled plate H, forming a reflector, and provided around its periphery with a series of small holes O by which part of the air passes into the globe G. A dome E integral with the chimney C covers the heater; it rests on the plate H and against the annular support N near the base of the chimney. The gas feed-pipe T passes down the centre, and is provided with the sleeve M^1 for preventing passage of water, &c., into the burner. It terminates below in a burner B of lance form, as shown in the drawing. The flame projector D cast with the

FIG. 1.

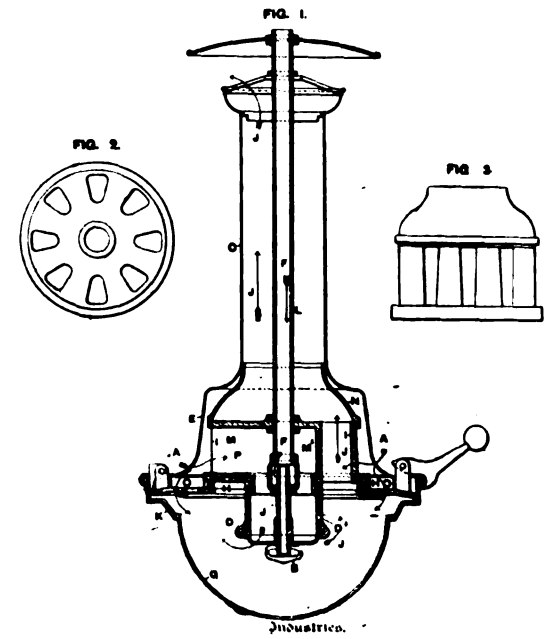

FIG. 2.

FIG. 3.

cylinder D^1 is fed with heated air and is ring shaped. The flame receives therefore the advantage of the radiation of heat from the projector, so that the whole surface of the flame is rendered active and the light thrown out in a horizontal plane. Claims: (1) A regenerator with inclined walls terminating in a cylindrical tube integral therewith, said tube having cast thereon an annular projector or guide for the flame for circulation of heated air, said tube being closed by a double metallic gauze projecting from the orifice; (2) the combination with a regenerator of a plate of enamelled iron having a series of holes in its periphery for passage of air into the globe, and carrying an exterior casing or dome integral with the chimney and leaning on an annular support on said regenerator, whereby the hot air is prevented from passing direct into the chimney; (3) a gas feed-pipe cut in two parts connected by a sleeve, the upper part terminating below in a hollow conical enlargement, the lower part provided above with a projecting nozzle; (4) the method of constructing the essential parts of the lamp subject to heat or exterior influence of cast iron enamelled within and without.—No. 16,379. November 12th, 1888. 6*d.*

MAKING GRINDING ROLLERS.—*J. E. Platt & J. Fidler, Oldham.*—The inventors cover the roller to be used as a grinding roller with a coating of glue or cement and emery. They then place the roller in a lathe and cause it to revolve in contact with another roller having a plain smooth surface, until the emery surface of the roller becomes level and circular and of the diameter required. They form a mould of suitable length, with the internal diameter formed of the same size as that of the grinding roller to be constructed, and in the interior of the mould there is a series of ridges and grooves, each of which is formed of a zig-zag or wave-like form. They cut the mould lengthwise into two or more portions. Instead of the mould being formed of one piece, having grooves and ridges on its inner surface and afterwards cut or divided into two or more portions or segments, the mould may in the first instance be formed in two or more portions which are held together in any suitable manner whilst the ridges and grooves are formed on its inner surface. The roller to be used as a grinding roller having been covered, and whilst the glue or cement and emery with which the roller has been covered is sufficiently plastic, the inventors enclose the roller in the mould by placing round it the portions into which it is divided, and enclose the whole by a ring or tube, and then compress the mould in any suitable manner upon the roller so as to impart to the surface of the glue or cement and emery a form corresponding to that of the interior of the mould. In order that the mould may be readily forced upon the roller, they form the outside of the mould of a taper form, and provide a ring or tube, the interior of which ring or tube is also formed taper. After the roller to be used as a grinding roller has been placed within the mould, and the tube or ring has been placed upon the outside of the mould, the whole is placed in a suitable press and the ring or tube is then forced upon the mould. Two claims are made.—No. 1373. January 25th. 8*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

ENGINEERING PROGRESS IN 1889.

GENERAL MECHANICAL ENGINEERING.

During the past year, although there has been no striking discovery or invention in the department of mechanical engineering, still there has been a steady development all along the line. It is to Americans that we owe almost all the most recent developments in the steam engine. Novel boilers, valve gears, and framings are all of American origin. There has not been much change in the manner of using the steam in the cylinders of steam engines during the year, although there has been a general tendency to the use of higher pressures. In land engines, the compound system is becoming more common, as the steam users are beginning to feel the necessity for economising fuel, and if the price of coal continues to rise, no doubt there will be greater attention paid to such matters. Triple and quadruple expansion is for the most part confined to marine engines. In marine engines, for pressures varying from 160lb. to 200lb. per square inch, quadruple expansion engines are now used, and of very various designs, the most usual being double tandem. One of the most ingenious designs which has come into use during the year is the quadruple expansion engine of Messrs. Fleming & Ferguson, of Paisley, in which the cylinders are all in the same plane, and the piston rods connected by a triangular crosshead to the two cranks. A considerable number of these engines have been made during the past year, and for the smaller sizes of vessels they have many advantages. The normal type of marine engine, however, is the triple expansion engine with the cylinders side by side, and each piston rod working on a separate crank, and for the usual pressures of steam this type is very suitable in every way. The engines of the steamers of the Inman and International line, the "City of New York" and the "City of Paris," may be mentioned as examples of the latest developments of marine engineering. These vessels have twin-screws, worked by two complete sets of engines in separate compartments. The engines are of the triple expansion type, working with a pressure of 150lb. per square inch. The boilers are worked under forced draught on what is known as the closed stoke-hold system. The new steamer of the White Star Line has also done some excellent performances, although somewhat below those of the "City of New York." Modifications are, however, being made in the propellers of the former, which may bring up her speed considerably. The excellent performances of these ships have, of course, raised speculations as to the future of the marine engine and of the marine boiler. The models of the hulls are excellent, and the engines are far ahead of the boilers. Attention is, therefore, being directed to the latter, and probably some form of water-tube boiler will be the next great step in advance in marine engines.

The machinery of our ships of war is as deserving of attention as that of the mercantile marine, and it involves many more difficult conditions, especially those regarding space and irregularity of employment. Whatever the reason may be, the engines of ships of war do not give the same satisfaction as those of the mercantile marine. Too often they break down when put to anything like a severe test, which would be a very serious matter if that test were actual warfare. The weakest part of the fleet has always been the boilers, and since the introduction of forced draught that weakness has been much increased, and therefore to this point the attention of engineers ought to be directed. In the matter of speed again, the ships of the navy very often fall behind what was expected of them. The subject of forced draught has been receiving considerable attention both in the navy and the mercantile marine during the past year.

We have hitherto known little of the efficiencies of marine engines, the consumption of coal in a given time being the only test applied. During the past year, however, the Institution of Mechanical Engineers published the results of a series of experiments on a marine engine, under the superintendence of its Research Committee, Professor Kennedy being the reporter. The experiments are useful, not so much for their results, for the engine under trial did not belong to the highest class, but rather for showing how experiments could be carried out without interfering to any great extent with the work of the ship.

Turning to locomotive engines, we find also considerable progress in several points. The President of the Institution of Mechanical Engineers in his address directed attention to the improvement made in getting rid of the exhaust steam to prevent the choking of the outlet, a condition which threatened to prevent the further development of speed on railways. During the year a considerable number of compound locomotives have been built, both in this country and on the Continent, and their use seems to be steadily gaining ground. A gain in economy of from 12 to 14 per cent. is said to be the result. In Russia, petroleum refuse is employed on some of the railways with fairly satisfactory results, but in this country it has not yet been practically applied. When coal becomes dearer, engineers will no doubt have some cause for trying a change.

The application of electricity to tramways and to locomotives is steadily gaining ground. The endless rope system of propelling tramcars is also being extended. Any one who has observed the great development of the system in America may well be surprised that greater advantage is not taken of it in this country.

Gas engines have attracted a considerable amount of attention during the year. The trials made by the Society of Arts, and the valuable report by the judges, gave us some accurate data and independent information as to their performances. There can be no doubt, however, that in spite of certain drawbacks gas engines have become a most important element in our industrial system, and are destined to have a still wider application. Hot-air engines are receiving more attention now than they did some years ago after the continued disappointments which inventors experienced, and for small sizes they are found useful and economical. That brought out by MM. Benier Brothers, Paris, contains several novel points, and gives fairly satisfactory results as regards economy. The spirit vapour motors introduced by Mr. Yarrow promise to be very useful for torpedo boats and work with good efficiency. They embody remarkable qualities for sea-going purposes, as might be expected from the lightness of the machinery, and they possess the great advantage of being able to get into action in two minutes.

The distribution of power by means of compressed air has been fairly successfully carried out in Paris by means of the Popp system, and during the past year it has received a great extension. The general problem of the distribution of power is likely to afford a wide field for ingenuity, as there is a growing demand for small motors for all kinds of purposes.

The various advances have led to the design of a great variety of special tools.

SHIPBUILDING AND MARINE ENGINEERING.

England and Wales.

The year which has just closed will long be remembered in shipbuilding, marine engineering, and allied industries, the aggregate output having beaten the record by about 100,000 tons of shipping. The prospects for the present year are, generally speaking, favourable, and it would be safe to prognosticate another output exceeding one million tons. In the accompanying tables we show a summary of the work in England and Wales, from which it will be seen the Tyne carries off the palm as the busiest shipbuilding river, having an increased output of over 68,000 tons over the previous year. The Wear, a good second, has, however, an increase of nearly 75,000 tons, and the Tees has also a very substantial increase of about 50,000 tons. Some marine engineering establishments have also been engaged in reboilering and converting compound into triple expansion engines, but the latter class of work has not been so plentiful as was anticipated in some quarters. Two reasons for this may be fairly advanced: (1) freights have been remunerative for old steamers with compound engines, and (2) the prices asked for altering engines to triple, and supplying boilers of higher pressures have necessarily been high, owing to the increased cost of material and labour.

Times of great activity do not usually appear to be very favourable to departures from everyday practice. However, quadruple expansion engines have been supplied to five steamers, four by Messrs. Wm. Allan & Co., Scotia Engine Works, Sunderland, and one of Tweedy's quadruple engines by Messrs. Wigham Richardson & Co., Walker-on-Tyne. For the converting of existing triple expansion engines into quadruple, as well as constructing new engines of the latter type, Mr. Thomas Mudd, the manager of the Central Marine Engineering Works of Messrs. William Gray & Co., of West Hartlepool, has recently patented a design, in which the high pressure cylinder is placed tandem fashion on the high intermediate, the low intermediate being placed forward and the low pressure abaft the high pressure cylinders.

Six of the shipbuilding centres in England may be considered of sufficient moment to justify the publication of tabular returns showing each shipbuilding firm's output for the last year:—

SCOTLAND.

During the past year there has been nothing very startling either in the way of the design or methods of construction of ships. There has, however, been a continuous development as regards dimensions, speed, safety, and strength of hull. The largest vessel built on the Clyde was the Red Star Liner "Friesland," over 7,000 tons, which was launched by Messrs. J. & G. Thomson, of Clydebank. Messrs. Napier & Son, of Govan, built for the Royal Mail Steam Packet Company, Southampton, two steamers, the "Thames" and the "Magdalena," both over 5,000 tons; Messrs. Denny, of Dumbarton, two of about 5,000 tons, one being the Pacific Mail Company's steamer "China," and the other the "Monte Video," for the Compania Transatlantica of Barcelona; the Fairfield Company, three steamers of about the same size, for the North German Lloyd. Large sailing vessels seem to be coming more into use, several of over 3,000 tons having been constructed during the year. The following table shows the sizes and numbers for the two past years:—

	1889.	1888.
Under 50 tons	49	27
100 ,,	27	18
500 ,,	48	58
1,000 ,,	20	34
1,500 ,,	13	17
2,000 ,,	27	22
2,500 ,,	25	17
3,000 ,,	16	17
4,000 ,,	24	12
Above 4,000 tons	10	9

from which it will be seen that the number of vessels built between 2,000 and 4,000 tons has considerably increased. The most important improvement carried out in the largest passenger ships is that they are made practically unsinkable by being divided into a sufficient number of water-tight compartments, and they have two complete sets of engines and boilers quite independent of each other. The use of steel has now become almost universal in the construction of ships, even sailing vessels being now almost all made of that material. On the Clyde for last year there was built of the total tonnage 97·2 per cent. of steel, so that for all practical purposes we may now speak of steel instead of iron shipbuilding.

Table I. shows the output at the most important ports in Scotland during the past six years:—

The great activity which prevailed in the industry last year had a very important effect on all the cognate industries, and prices and wages have accordingly risen to a very great extent. In steel and iron there has been a rise of at least £2 10s. per ton, which on the prices current at the beginning of the year was about 20 per cent., while malleable iron has risen almost 30 per cent. during the past six months. Part of this is, no doubt, due to the speculation which has taken place, but the greater part is due to increased demand. The same remarks apply to all the materials of construction. Wages have, of course, increased, and, although there have been a few disputes, there has been an absence of long strikes. It is becoming increasingly evident that both employers and employed are beginning to see the evils of strikes and lock-outs. The latter, of course, have long had their trades unions, and during last year the Clyde Employers' Association has developed into a National Federation.

It is interesting to note the nationality of the ships which have been built on the Clyde during last year, as we thereby have an index of the probable amount we may expect in the future. Out of a total of 80 built for foreign countries, Germany heads the list with 14, which shows that, notwithstanding the progress that country has made in shipbuilding, it finds its wants can be better supplied, at least for the larger ships, in this country than anywhere else. The same number were built for countries in South America, a continent which is capable of immense development, and which is well deserving the attention of our capitalists, engineers, shipbuilders, and manufacturers. Then we have for Australia 7, a number which is very small compared with what is likely to be required in the not very distant future; for Portugal 6, Spain 5, France 2, Japan 2, China 2, Canada 4, United States 1, Belgium 1, South Africa 1, and India and other countries 14, giving for the 80 vessels a tonnage of 115,272 tons. For Scotch owners there were built 67 vessels with a tonnage of 104,977 tons. For owners in London there were built 20 vessels with a total tonnage of 44,599, in Liverpool 19 vessels with a tonnage of 43,975, and in other ports 59 vessels with a tonnage of 19,878. The British Government had 4 vessels with a tonnage of 6,810.

The returns we give in Table III. have been published as the output of the respective yards, and of the horse-power of the engines in the cases where the shipbuilder also constructed the machinery.

In addition to the engines of which the horse-power is given in the annexed table, a great many more have been built by makers who are not shipbuilders. Table IV. gives an abstract of the work of such makers during the two past years.

During the past year no steamer built on the Clyde has had the engines made elsewhere, and in addition to those required for Clyde-built ships, the engineers have constructed 24 sets of machinery of 20,880 i.h.p. for vessels built in other ports, and have also refitted 10 steamers with triple expansion instead of the ordinary compound engines of 15,275 i.h.p.

The estimated value of the ships built on the Clyde during the past year may be put down at about £7,500,000, compared with £5,600,000 in 1888, £4,400,000 in 1887, £4,100,000 in 1886, £4,000,000 in 1885, £7,000,000 in 1884, and £10,000,000 in 1883. In the last-named year the tonnage was 419,664 and the horse-power about 315,000, and prices were even higher than they are at present.

The prospects for the present year on the Clyde are very good, there being now in the various yards, and in different stages of construction, 166 vessels, aggregating 300,629 tons, the whole of which will be launched during the year, and in itself represents a good average year's output.

In Dundee, from which shipbuilding had almost disappeared during the depression of 1885-87, there has been a great improvement. In 1888 there were 8 vessels, with a tonnage of 11,197, launched. Last year there were launched 13 vessels of 17,668 tons, and about the same amount remains on hand.

In Leith the past year has been one of the best in the history of the trade, there having been constructed 17 vessels, with an aggregate of 17,776 tons; and one of these, by Messrs. Ramage & Ferguson, was the largest vessel yet built in the port, being of 3,300 tons, and fitted with engines of 1,800 i.h.p. She was built to the order of Messrs. Money Wigram & Co., of London.

In Aberdeen there were launched 11 vessels, of 9,380 tons, the largest number and the greatest tonnage turned out at the port since 1883. At some of the smaller ports a considerable number of smaller craft were built, but nothing calling for special notice.

IRELAND.

In Ireland, Messrs. Harland & Wolff, of Belfast, launched 12 vessels, of an aggregate tonnage of 56,430, and 51,800 i.h.p. The two most important of these were the White Star liners, "Teutonic" and "Majestic." Of the 12 vessels built by this firm, it is remarkable that they were all above 3,000 tons, which shows that there is a tendency for the sizes of ordinary merchant steamers to increase. Messrs. Workman, Clark, & Co., of Belfast, constructed 6 vessels, 1 sail and 5 steam, the tonnage being 21,112 and the horse-power 9,800: while the new firm of Messrs. MacIlwaine & Maccoll, also of Belfast, made a fair start with 4 steamers of moderate size, 2 small sailing vessels, besides reboilering and compounding 2 vessels. At Londonderry Mr. Charles J. Biggar, Foyle Shipyard, launched 5 vessels, aggregating 7,268 tons.

CIVIL ENGINEERING.

First among the engineering works completed during the year 1889, both as regards magnitude and skill in design and execution, stands the Eiffel Tower. As to its utility, there may, from the general point of view, be some question, but there can be no doubt whatever that it constitutes one of the most remarkable monuments of constructive ingenuity ever achieved. To its promoters, too, it has proved an extremely useful instrument for the transfer of wealth from the pockets of the French and cosmopolitan public visiting Paris to their own; whether, while being instrumental in redistributing wealth, it has tended to equalise it, is quite another matter. To the Eiffel Tower it also seems probable that the sincerest form of flattery will be accorded, as both in this country and in America designs for rival towers have been or are being prepared. While it is probable that these will exceed their prototype in mere size, it is extremely unlikely that they will excel it in elegance of form or constructive skill, and at the best will take a second rank as mere imitations without the same excuse for their existence as the original. Of the Eiffel Tower such a full account has appeared in our columns that any recapitulation of the leading particulars is here unnecessary. As is our usual practice, we shall review under their respective headings the various branches of civil engineering.

Bridges.

The Forth Bridge is now approaching final completion, and as yet no rival undertaking of a similar kind has any prospect of being carried out in the immediate future. We have kept our readers so fully informed of the progress of this great work that any further reference here is unnecessary.

In England, no large bridges of any importance have been completed within the year now coming to a close, and the only new topic of interest in connection with this branch of engineering is the proposed Channel Bridge. Whether this gigantic scheme ever gets beyond the paper stage is a matter on which we should not care to commit ourselves to a definite prophecy. There certainly are some objections to the execution of such a project, quite apart from the engineering difficulties, which, given time and money, would probably not be insuperable. We think those interested in shipping may protest against the construction across a crowded water-way of a series of obstructions at intervals of less than a third of a mile. It has, we believe, still to be shown how, when constructed, the money necessary to realise a reasonable profit on the capital expended and pay interest during construction is to be earned. The estimated cost of the bridge is £34,000,000; to pay 3 per cent. only on this would require £1,020,000 per annum, in addition to the cost of maintenance and working expenses, which latter would probably have to include those necessary for keeping powerful lights burning on each of the piers.

A scheme for a new bridge across the Clyde at Glasgow has for some time been under the consideration of the authorities. Various suggestions have been made, but a proposal of a definite character has recently been placed before the Clyde Trustees by Mr. Wm. Arrol, the contractor for the Forth Bridge. According to this proposal, the river is to be crossed, at Finnieston, by a single span of 430ft., with a roadway 100ft. above the top of the quay wall. The approach would be by an incline 2,000ft. in length, with a gradient of 1 in 20. The width of the roadway would be 40ft. and that of the footpath 10ft. Under this bridge large vessels could pass by lowering their topmasts.

The Manchester, Sheffield, and Lincolnshire Railway Company have built a new bridge over the Dee at Connah's Quay. It consists of two spans of 120ft. each and a swing girder giving a clear waterway of 140ft. on one side and 80ft. on the other.

Among large bridges recently completed abroad may be mentioned the Sibley Bridge, over the Missouri, on the Chicago, Sante Fé, and California Railway. This structure includes three spans of 400ft. each and one of 250ft., while the total length of iron bridge is 3,900ft. The main spans of 400ft. are chiefly of mild steel and the remainder of wrought iron.

Over the River Hudson at Peekskill a bridge is being built, the foundations of which are now nearly ready. This bridge will have a span of 1,620ft., and be of the suspension type, with cables of crucible steel, without joints, welds, or tucks.

Canals.

Many of the projected canals to which we referred in our review of civil engineering for last year still await inception, while in the United Kingdom no new work of this description has been commenced. The Manchester Ship Canal progresses steadily, and to this great work we devote a special article. To the list of proposed new waterways must now be added the canal from the Forth to the Clyde. Two alternative schemes for this have been brought forward; one for deepening and widening the existing canal, the other for an entirely new canal which would include part of Loch Lomond, and utilise the river Leven from its junction with the Clyde to the Loch, deepening it where required. The former suggestion finds most favour. In Canada the ship channel from Montreal to Quebec was opened on November 7th, 1888, and has during the present year come into use. This work has been in progress for about fifty years, the channel having been from time to time deepened to meet the requirements of vessels of increasing tonnage. The depth is now 27½ft., and the minimum width 300ft. A very large proportion of the work has been through the marshes and shallows of the Lake of St. Peter. Another canal in progress is the Kootenay Canal, connecting the south end of the Columbia Lake with the Kootenay River. When completed this will establish communication by steamer between the Columbia River and the fertile Kootenay valley, which has hitherto been shut off from the rest of the world by the absence of adequate means of transport. The length of the channel will be about 1¼ miles, with a lock between the Kootenay River and the lake, the latter being 11ft. lower than the former. In Japan, a canal is being constructed to supply Kioto, the ancient capital of Japan, with water from Lake Biwa, about seven miles distant. The water is intended mainly for irrigation and manufacturing purposes, but there is no reason against its being used for drinking. Lake Biwa lies about 140ft. above Kioto. In the first instance the main canal will be employed for supplying the existing canals in the city, but subsequently a reservoir is to be made, from which water will be carried into Kioto by mains. Among other projected water channels may be mentioned one to unite the Kattegat with lake Venern. The length will be about 12 miles, including 4 miles of lakes, and the depth 21ft., allowing the passage of vessels of 3,000 tons. The scheme for making Paris a seaport has not, we believe, so far assumed any very definite shape.

Work has recently been commenced on the Nicaragua Canal, of which we quite recently gave an account.

Dock and Harbour Works.

On the 18th of July last the Barry Docks at Cardiff were formally opened. In our review last year we gave a brief account of the leading features of this important work, and more detailed particulars in connection with the account of the opening in our issue of July 26th, 1889. The total area open is 557 acres, and at low tide vessels of 16ft. to 17ft. draught can enter through the gates. At Glasgow new docks are in course of construction, the present accommodation for vessels having been found insufficient. These new docks comprise three parallel basins, each 200ft. in width; the length of the water area is 2,000ft., the extreme width 1,100ft. For Ardrossan Harbour, an additional wet dock, 9 acres in extent, is being constructed, which at high water will have a depth of 27ft. Outside this is formed a tidal basin of 5 acres area, with 18ft. of water at low and 27ft. at high tide. Besides these, a new breakwater is being built for protection against the north-west gales; this will have a length of 2,000ft., is 28ft. wide at the bottom, and is composed entirely of concrete. New quays and quay walls are being added, and the entrance channel deepened. The old wet docks have an area of only 4 acres, with a depth of water of 18ft. At Hartlepool the new marine promenade and headland protection works were lately opened. They were built to protect the cliff against the action of the sea, by which it was being rapidly undermined. The works consist of a concrete wall formed along the face of the cliff, to a height of 17ft. 8in. above the high water mark of ordinary spring tides. The length is 3,400ft., the minimum width 20ft. Among harbour improvements abroad, those now approaching completion in Calais Harbour deserve notice. This work was commenced in 1876, and has ever since then been in progress. The chief improvements consist in a new outer harbour basin of about 15 acres, a floating basin of about 30 acres connected by locks with the former, and a sluicing reservoir with a present area of 35 acres at ordinary high tides. By dredging and sluicing a minimum depth of 10ft. is maintained at the lowest tides, while at high tide the corresponding depth is 36ft. For a distance of 1,300ft. beyond the jetties the outer channel has been deepened by about 12ft. For this purpose, between January, 1883, and December, 1888, about 1,152,000 cubic metres of sand were removed. Throughout the harbour hydraulic machinery is employed for working sluices, lock-gates, swing-bridges, capstans, &c., the power being supplied from a central station on the quay. The entrance to the locks connecting the outer harbour basin with the floating basin is crossed by four swing-bridges; two with spans of 91ft. 10in. each, and two with spans of 68ft. 10in. each. For the improvement of the port of Havre very extensive works are contemplated, the chief of which will be a new entrance in deep water and an extension of the dykes in the Seine, together with breakwaters to protect the entrance from the violence of the waves.

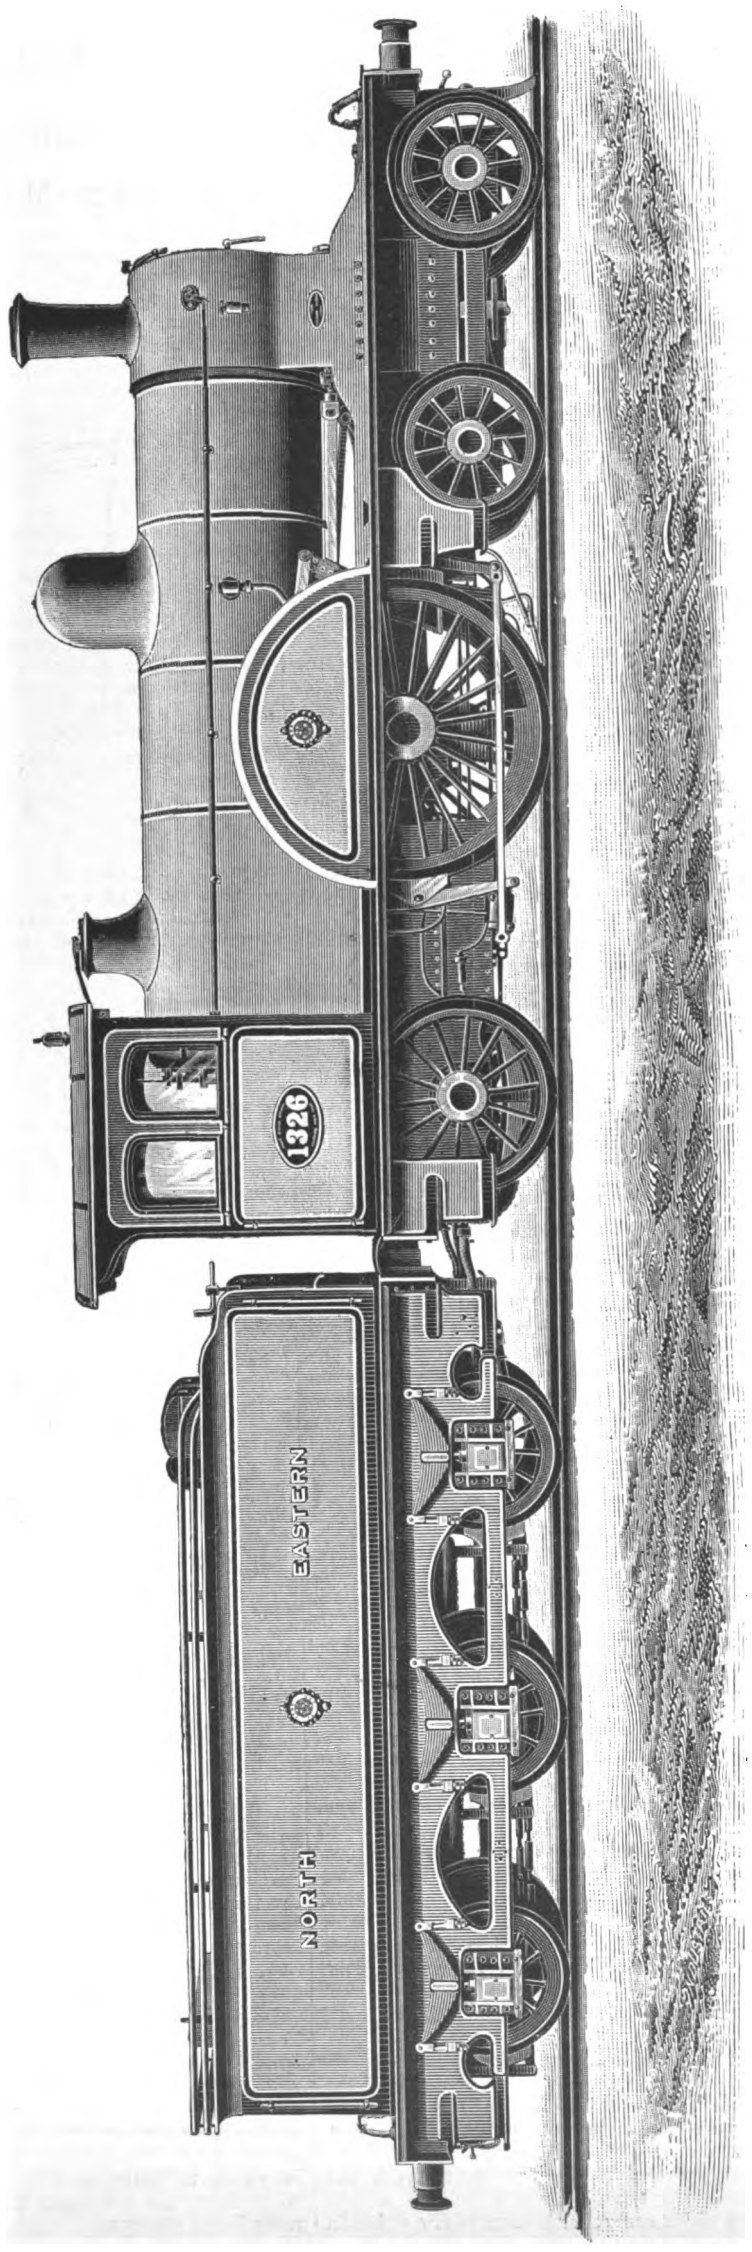
Railways.

In this country no railway enterprises of any magnitude are now to be expected, and any work of this kind that may be carried out is chiefly in the nature of improvements or short branch lines. Nevertheless, it seems not improbable that there is a greater scope for new undertakings in this direction than is generally imagined, more particularly in the matter of providing cheap mineral and goods transport by special lines equipped with rolling stock of great individual carrying capacity. With this, however, we cannot at present concern ourselves, but must return to the consideration of work accomplished. The Lancashire and Yorkshire Railway Company have in the present year completed an extension which enables them to have a fast express service between Liverpool and Manchester by avoiding the detour through Wigan and Bolton. The new line passes through Pemberton and Pendleton, at which latter place it departs from the previously existing railway system. On this length of railway there are no steep gradients or sharp curves, but it involved in other respects some rather heavy work, including ninety-three substantial bridges. The work was commenced in April, 1885. The cost has been about £750,000. Early in last June the new Fulham and Wimbledon Railway, forming part of the South-Western Railway Company's system, was opened for traffic. The total length is about four and a half miles, and includes a fine trellis girder bridge over the Thames, besides other heavy work in the shape of cutting tunnels and embankments. The Metropolitan District Railway Company has running powers over the new line.

Turning our attention from the mother country to her colonies and foreign possessions, we find that in Canada the Grand Trunk Railway has doubled its main line between Montreal and Toronto at a cost of £41,410, while a short new branch, the South Norfolk Railway, 17 miles in length, has been constructed from Simcoe to Port Rowan on Lake Erie. The Northern Pacific Railway from Tacoma on Paget Sound to Duluth on Lake Superior has already commenced the construction of a series of railways in Canada to form an outlet from the wheat-growing country in the North-West to the Atlantic, thus competing seriously with the Canadian Pacific Railway. This activity on the part of the Northern Pacific Railway Company gave rise to the dispute which occurred not long since in Manitoba, which was decided against the Canadian Pacific Railway. Three lines are either finished or in course of construction in Manitoba: one from Winnipeg City due south to the international boundary, 65 miles in length; a second branching off from this south of the Assiniboine River, and then running due west to join at Portage the Manitoba and North-Western Railway, length 65 miles; and, thirdly, a line commencing 20 miles north of the frontier, and establishing communication with the North-West Central Railway now being built. This new line, 130 miles long, will cross the Canadian Pacific, taking generally a north-westerly direction. In British North America, including Novia Scotia, about 400 miles of railway have been laid in 1889.

In the United States over 3,000 miles of track were constructed during the period from January to October of 1889.

In India, the largest piece of railway work now in hand is the Bengal Nagpur line, which, when completed, will very materially shorten the journey from Bombay to Calcutta. Another line, which is rapidly progressing, is the Villupuram-Dharmavaram State Railway, 301 miles in length. Besides these numerous short extensions are in hand. In Burmah a survey is being carried out for a railway up the Mu Valley from Sagoing, 10 miles below Mandalay on the right bank of the Irrawaddy, to Mogaung, with branch line to Bhamo.



Throughout the Argentine Republic, railway construction has been prosecuted with great energy during the present year, and numerous new concessions have been granted. The Government refuses, however, to give further guarantees, but in spite of this new enterprises are taken up. An extension of the Northern Central has been opened beyond Tucuman as far as Chilias, and branches to Chilicito and Catamarca are in course of construction. The line from Mendoza towards Valparaiso continues to make progress.

In Japan the whole of the railway system connecting Tokio, Yokohama, Kioto, and Osaka, has been opened for traffic for a length of 278 miles. In the mountainous district near Fusigama the works are heavy, comprising numerous tunnels and many bridges. The largest and most important of the bridges is the Tenriugawa bridge, which has 19 spans of 200 feet each. The total length of the railways now open in Japan is 752 miles, while there are 455 miles under construction and 216 miles being surveyed.

COMPOUND PASSENGER LOCOMOTIVE.

BUILT BY THE NORTH EASTERN RAILWAY COMPANY, FROM THE DESIGNS OF MR. T. W. WORSDELL, M.I.C.E., LOCOMOTIVE SUPERINTENDENT.

The detail plans are now ready for a new Alpine railway up the Säntis in the canton of Appenzell, in Switzerland. This line will rise from 2,600ft. to 6,700ft. above the sea level, will have a length of 9¼ miles, and a maximum gradient of 24 per cent. The first portion of it, for about four miles, will follow the valley, and on this section ordinary locomotives, working by adhesion, will be used, but on the remaining portion a rack locomotive will be required. A proposal for a railway up the Säntis was brought forward many years ago, but the concession was only granted in 1887. The latest project for a mountain railway is the scheme for the ascent of the Jungfrau, the audacity of which we are compelled to admire, whatever may be our opinion as to its æsthetic aspects or necessity.

COMPOUND PASSENGER LOCOMOTIVE.

DURING the meeting of the members of the British Association last year at Newcastle various excursions were made, and one of the most interesting was that to the North Eastern Railway Works at Gateshead. We referred to this excursion in our issue of the 4th October last, and promised to give an illustrated description of the largest and most recently built compound express passenger engine, as made from the patented designs of Mr. T. W. Worsdell, M.I.C.E., the locomotive superintendent.

This we are now enabled to do through the courtesy of Mr. Worsdell, and in our two-page supplement this week we show a sectional elevation and plan of this engine, while on this and the next page we give a general view and a transverse section of the engine respectively. The general particulars are tabulated below:—

	Ft.	In.
High-pressure Cylinder:		
Diameter of cylinder	1	6
Stroke of piston	2	0
Length of ports	0	11¾
Width of steam ports	0	1¾
„ exhaust ports	0	3½
Distance from centre line of cylinder to valve face	1	1
Slide valve, Trick pattern, ports ½in. wide	0	0½
Lap of slide valve	0	1⅛
Maximum travel of valve	0	5¼
Lead of slide valve	0	0 3/16
Inside clearance of valve	0	0¼
Distance apart of cylinders, centre to centre	2	0
Distance apart of slide spindles, centre to centre	2	0
Low-pressure Cylinder:		
Diameter of cylinder	2	2
Stroke of piston	2	0
Length of ports	1	5
Width of steam ports	0	2
„ exhaust ports	0	3½
Centre line of cylinder to valve face	1	5
Lap of slide valve	0	1⅛
Maximum travel of valve	0	5¼
Lead of slide valve	0	0 3/16
Inside clearance of valve	0	0⅛
Motion:		
Diameter of piston rods	0	3
Length of slide blocks	1	3
„ connecting rods between centres	6	1
Wheels (cast steel):		
Diameter on tread (bogie)	3	7¼
„ „ (driving)	7	1¼
„ „ (trailing)	4	7¼
Thickness of tyres on tread	0	3
Width	0	5½
Crank Axle (steel):		
Diameter at wheel seats	0	9
„ bearings	0	8
„ centre	0	7¾
Distance between centres of bearings	3	10
Length of wheel seats	0	7 7/16
„ bearings	0	9
Diameter of crank bearings	0	8¼
Length „	0	5
Distance between centres of cranks	2	0
Bogie Axle (steel):		
Diameter at wheel seats	0	7½
„ bearings	0	6
„ centre	0	5¾
Length of wheel seats	0	7¼
„ bearings	0	9
Distance between centres of bearings	3	7
Trailing Axle (steel):		
Diameter at wheel seats	0	8⅓
„ bearings	0	7
„ centre	0	6¾
Length of wheel seats	0	7⅜
„ bearings	0	11
Distance between centres of bearings	3	8

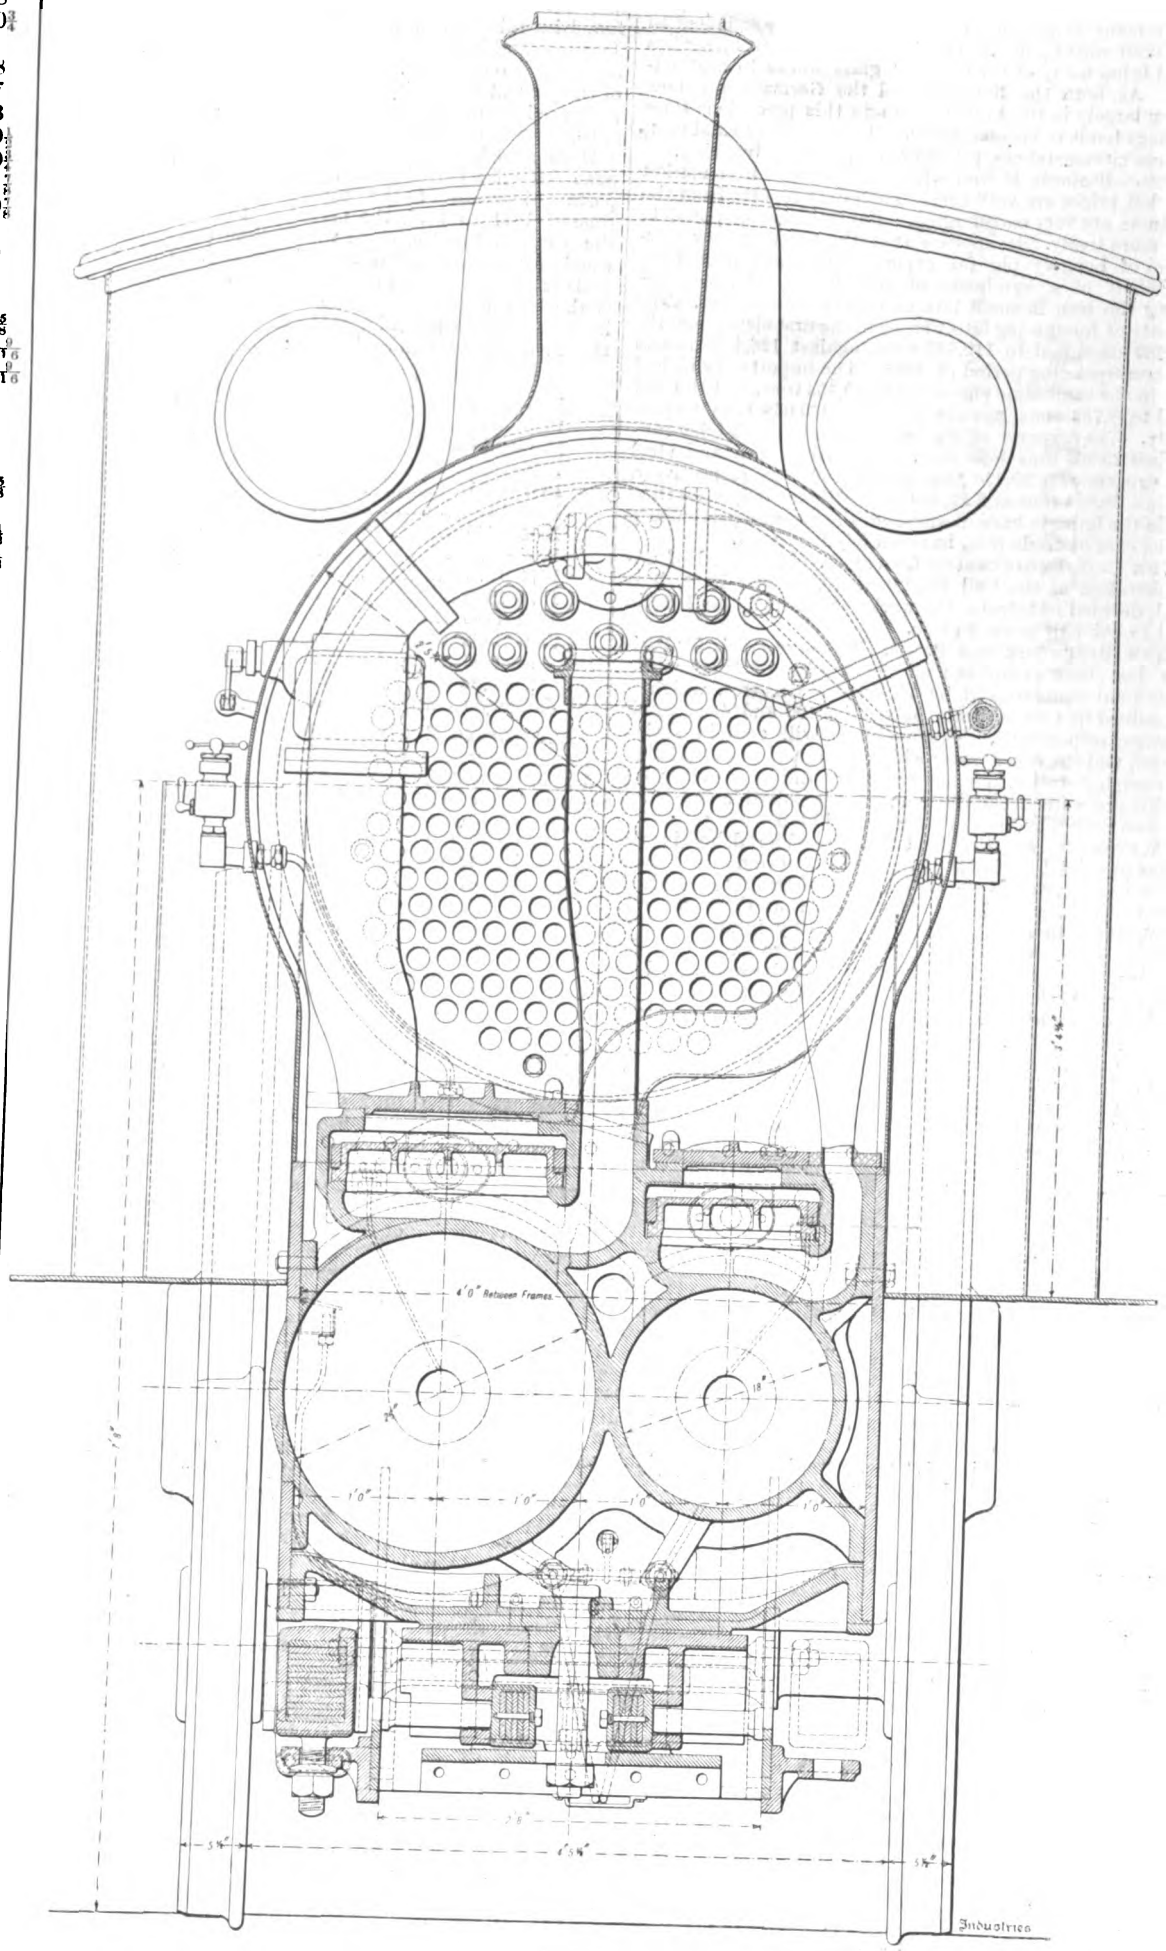
COMPOUND PASSENGER LOCOMOTIVE.

Built by the North Eastern Railway Company, from the Designs of Mr. T. W. Worsdell, M.I.C.E.

	Ft.	In.
Frames (steel):		
Front centre of bogie to front buffer beam	5	3
Centres of bogie wheels	6	6
From centre of bogie to centre of driving wheels	10	0
From centre of driving wheels to centre of trailing wheels	8	8
From centre of trailing wheels to back end of frame	3	3
Distance apart of frames	4	0
Thickness of frame	0	1
Distance apart of bogie frames	2	8
Thickness of bogie frames	0	0¾
Boiler (steel):		
Height of centre of barrel from rails	7	8
Length of barrel	10	7
Diameter of barrel outside	4	3
Thickness of plates	0	0½
„ smoke-box tube plate	0	0⅝
Pitch of rivets	0	1⅞
Diameter of rivets	0	0⅞
Fire-box Shell (steel):		
Length, outside	6	0
Breadth, outside at bottom	3	11
Depth below centre line of boiler	5	0
Thickness of throat plate	0	0⅝
„ sides and top plate	0	0 9/16
„ back plate	0	0 9/16
Pitch of copper stays	0	4
Diameter of copper stays	0	1
Roof stays, cast-steel, girder section		
Inside Fire-box (copper):		
Length of bottom, inside	5	3⅝
Breadth „ „	3	3
Top of box to inside of shell	1	3½
Depth of box inside	5	9½
Tubes (brass):		
Number of tubes, 203		
Length between tube-plates	10	11⅛
Diameter, outside	0	1¾
Thickness, No. 11 and No. 13 B.W.G.		
Height of chimney from rail	13	0

	Sq. ft.
Heating surface of tubes	1026·12
„ firebox	110·00
Total	1136·12
Grate area	17·23

Working pressure, 175lb. per square inch.



Weight of engine (empty):	Ton.	cwt.	qr.
Bogie wheels	13	14	0
Driving „	16	6	2
Trailing „	9	10	2
Total weight	39	11	0
Weight of engine (full):

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 33.)

PARIS, 7TH JANUARY, 1890.

COAL.—The state of the coal market is giving rise to much anxiety. From all quarters we hear of a short supply. Here in Paris there is a serious scarcity, and in the provinces many large consumers have only just sufficient to keep their works going. The least interruption by strikes would bring many of the iron and glass works to a standstill. As both the Belgians and the Germans are now buying largely in the French markets this precarious state of things tends to become worse. It is needless to add that, in these circumstances, prices are constantly advancing.

IRON.—Business is somewhat slack in the iron market here, but prices are very firm. The latest reports from the provinces are very encouraging. Buyers seem disposed to deal more freely. It appears that the recent heavy purchases of Longwy pig for export to Germany were made on behalf of a syndicate of speculators, who are now selling the iron in small lots to German consumers. The imports of foreign pig into France in the first eleven months of 1889 amounted to 110,692 tons, against 126,401 tons in the corresponding period of 1888. The imports of finished iron in the same time amounted to 25,453 tons, and those of steel to 8,752 tons, against 32,100 and 9,038 tons respectively. The exports of pig iron amounted to 91,699 tons against 23,968 tons last year. Of finished iron and steel the exports were 59,220 tons and 29,759 tons respectively, against 30,034 tons and 13,359 tons. Hence it appears that, while the imports have diminished, the exports, particularly in the case of crude iron, have notably increased.

THE CAIL ENGINEERING COMPANY.—The board of administration of the Cail Engineering Company have, it is said, decided to transfer the works at Grenelle to Denain and Douai, half to each place.

NEW RESERVOIR FOR PARIS.—A new reservoir for Paris has just been completed on the heights of Montmartre, The total contents will be 11,000 cubic metres, which is contained in two separate bulks of 6,200 and 4,800 cubic metres respectively. One reservoir will contain spring water, and the other water which is pumped from the Seine. A pumping station is being erected at the base of the hill to lift the water from the Seine, the installation consisting of two Corliss engines of a total of 140 h.p.

ACCIDENTS WITH STEAM PLANT.—The delay in the issue of official statistics is proverbial. From the returns of boiler and steam engine accidents during 1888, which have just been published, it appears that there were 17 explosions, 19 persons killed, 9 seriously injured, and 12 slightly hurt. Of the 17 explosions, 9 were caused by defective construction, 5 by negligence or imprudence, 2 by unpreventible accidents, and 1 by an unknown cause.

A NEW SUBMARINE BOAT.—Further particulars are to hand regarding M. Apostoloff's new submarine boat. The boat is 28m. long and 3·25m. in diameter, and it has accommodation for 20 to 25 persons. It consists of two shells. It can descend to a depth of 22 metres, and the supply of air will allow of a submersion of 38 hours. At a depth of 20 metres the speed is 12 knots per hour. A new electromotor has been specially designed for the boat, but no information is obtainable regarding its construction.

BERLIN, 6TH JANUARY, 1890.

GERMAN IRON ABROAD.—The German export trade in iron was fairly active in the month of November, the total, as shown by the Customs returns, being fully up to the average for the season. The following classified record shows the quantities for the month, and also for the eleven months of 1889 ending with November: Pig iron, 11,962 (147,155) tons; old iron and scrap, 1,746 (31,544) tons; half-wrought iron and steel, 1,950 (19,194) tons; finished iron and steel, 20,780 (261,912) tons; wire, 13,118 (146,195) tons; wire nails, 3,479 (42,724) tons; rails, 11,920 (101,593) tons; other railway iron, 3,991 (48,133) tons; heavy castings, except ordnance, 1,800 (17,541) tons; other manufactured goods, except machinery, 10,607 (110,488) tons. Total, 81,353 (926,479) tons. The quantity of iron and steel wire shipped to great Britain in November amounted to 2,941 tons, making 31,284 tons for the eleven months. The shipments of wire nails to great Britain in the same period amounted to 810 tons and 11,518 tons respectively. Of the wire-nail exports, 8,938 tons were sent to Japan.

PRICES OF PHOSPHORIC SLAG.—As the value of phosphoric slag as a manure becomes known the demand increases and prices advance. The best possible evidence of the growing importance of the trade in this substance, formerly a waste product of the iron industry, is afforded by the rapid advance in prices in the year 1889. At the beginning of that year 38s. per ton was the quoted price. From this the price rose to 42s., 46s., 48s., 50s., and 51s. At the present time the market is firm at 51s.

PHOTOGRAPHIC EXHIBITION.—In the course of the present month an important national exhibition of photographs will be held in Breslau, in which it is expected that English and American photographers will take a large part. Instantaneous photography is to be made a feature of this Exhibition. The papers to be read are likely to be of a very interesting character.

VIENNA, 6TH JANUARY, 1890.

THE COAL MARKET.—Circumstances have not changed, and the markets are in the same position as last week. The continued strike in the Westphalian collieries has had an important influence on the Western Bohemian district, where a strong activity is displayed. During the last week 17,629 waggons of Bohemian brown coal have been exported to Saxony.

THE IRON MARKET.—The feature of the iron market at the present moment is a scarcity which has not been equalled for many years. The animation is still sustained, and prices continue to tend upwards. The Bohemian foundries raised their prices by 25 per cent. on the 1st of January, and in other branches of the market a steady tendency is observable. It may be mentioned as indicative of the present prosperity that Messrs Ganz & Co., of Budapest, are intending to pay a dividend of 17 per cent.

RETROSPECT OF THE AUSTRO-HUNGARIAN COAL TRADE.—During the last thirty years the export trade of coals has gone through a period of steady increase. The most important increase of the export took place during the time of 1871 to 1875, the period of the establishment of the German Empire, since which time there has been a wonderful evolution of German industries. The import of coals has also increased considerably, a circumstance which is the best testimony of the amelioration of our home industries. The following table shows the development of the Austro-Hungarian coal trade:—

	Import. Tons (= 1000kg.)	Export. Tons (= 1000kg.)
1831–1835	14,285·7	2,219·6
1836–1840	20,442·5	14,123·7
1840–1845	32,551	37,141·6
1846–1850	47,470	54,201
1851–1855	102,363	85,523
1856–1860	183,227·8	184,393·5
1861–1865	325,673	342,516·8
1866–1870	576,412·7	753,415·7
1871–1875	1,598,467·8	1,751,796
1876–1880	1,858,498	3,285,307
1881–1885	2,407,612	3,902,687·5
Jan. 1886	2,721,279	4,504,509·7
„ 1887	2,874,756	4,747,988
„ 1888	3,150,936	6,120,542
January to August, 1889	2,195,408	3,607.742·5

ELECTRICAL ENGINEERING.—The electric lighting of Vienna progresses very slowly, and it meets with a great deal of influential opposition in all quarters. For instance, the project of the central station at Neubad, from which 60,000 lamps were to be supplied, has been before the public for six years, but up to the present time M. Fischer and Siemens & Halske have only been able to complete sufficient plant to feed 5,000 lamps. The project of Professor Engländer has not fared any better. It took him three years to persuade the authorities and the public in general as to the advantages of having a central station in Copernicus-Gasse. At present 12,000 glow lamps are being supplied from the station by means of five vertical high-pressure steam-engines and ten dynamos of various types. Accumulators are employed to equalise the day and night duties of the machinery. The whole installation is erected on very good lines, and it supplies a large number of important buildings. The International Electricitäts Gesellschaft are pushing on their central station. During the past year Messrs. Ganz & Co. have brought out an alternating current motor, a wattmeter, a new transformer for their high-power wattmeter, and an electric railway.

TELEPHONE TRUNK LINES IN AUSTRO-HUNGARY.—At the beginning of the year the telephone line was opened between Vienna and Budapest, a distance of 282 kilometres. This is the fourth line which has been erected between towns in the Austrian Empire, the others being between Vienna and Brünn, 177 kilometres; between Vienna and Reichenau, 115 kilometres; and between Vienna and Prague, 310 kilometres.

BRUSSELS, 7TH JANUARY, 1890.

THE COAL MARKET.—In spite of the great activity in the transport of coal over the Belgian railways, the consumers complain most bitterly of the irregularity of the supplies, and of the poor qualities of the coal and coke which is sent to them. Work at the rolling mills, the blast furnaces, and the glass works is thoroughly disorganised. If anyone wants a quick delivery of coal or coke he has to pay a tremendous price, varying widely at different collieries. During the past week the State Railways have transported 28,957 waggon-loads as compared with 28,409 during the same week of 1888. The position of the trade is much the same. The strike continues, and there does not appear to be any likelihood of an immediate resumption of work. The coal owners are determined to resist, and work will therefore be suspended until the men come round. There is no coal-getting being done in the Charleroi district, and English and German coal is therefore being imported, thus making it possible for some of the manufactories to be carried on. The strike is equally persistent in Liège, and the coal owners are very anxious. The collieries of the Société Cockerill have a great many strikers, but the directors rather than give in have ordered large amounts of coal from England and Germany, in order to keep their steel works going. Two vessels laden with American coal have arrived to supply the Charleroi district, but it is taxed very heavily.

THE IRON MARKET.—The scarcity of fuel has thrown the iron trade into a state of great perturbation, for many manufactories have been forced to cease work in the absence of coal and coke. The demands for iron are therefore beginning to be transferred to other quarters. The prices of all kinds of products are firm. Pig iron is well held; red short is quoted at 80fr., and good brands at 90–100fr. The sellers are trying to force the prices up still further, but it would be wiser to try to establish the present prices on a firmer basis.

GLASS WORKS.—No business has been done during the past week owing to holidays and strikes. If the coal strikes continue much longer the glass makers will have to cease work altogether, and so bring upon themselves an enormous loss. They are taking as many precautions as possible by ordering supplies of foreign coal, and are thus encouraging industries which have long been rivals to Belgian coal workers.

ELECTRIC LIGHTING IN BRUSSELS.—The municipal authorities of Brussels have determined not to grant the contract for lighting the city to the German firms, but they have not decided yet who is to have the contract. The solution of this problem, which gives so much trouble to the city fathers, is really very simple. Here there are two native electric supply companies—La Société l'Electrique and M. Rysselberghe—both of them of good reputation, and both capable and willing to do the work at advantageous terms for the public. Why the Council cannot decide the question is an enigma to reasonable beings.

THE BELGIAN EXHIBITION IN LONDON.—Arrangements are mostly completed regarding the Belgian Exhibition to be held in London during the coming summer. The private and public guarantee funds amount in all to 600,000fr. The Belgian committee have settled all the points of dispute with the English executive, and are able to include the transport charges from Belgium to London in the fee for letting the space in the Exhibition.

DÜSSELDORF, 7TH JANUARY, 1890.

COAL.—The course of events tends to increase the scarcity of coal in this district. Consumers of Belgian coal are buying German produce now that the output of the Belgian pits is interrupted by the strike, and the influenza has diminished the production of the German pits fully 20 per cent. The effect on prices has shown itself in a rise of 6d. a ton for coal and 1s. for coke. The coalowners in the Halle district have raised the price of briquettes to 14s. a ton. The new wharfs for Westphalian coal at Hamburg were opened to-day. The reduction of 5s. per 10-ton truck load to Hamburg came into operation on January 2nd. These are matters of great importance to the English trade in coal with Hamburg.

IRON.—The iron market is active again, and the prospects of trade in 1890 appear most encouraging. The Rhenish-Westphalian syndicate of rolled iron manufacturers have begun the year with an advance in prices, bars being now quoted 200s. a ton. The progress of the pig iron market in 1889 is set out in the following figures, which represent the price in shillings per ton on the last day of each month:—Spiegel, of 10 to 12 per cent manganese, 59, 62, 63, 63, 66, 66, 67, 70, 76, 77, 85, 102; Rhenish-Westphalian forge, 52, 54, 54, 57, 58, 62, 62, 64, 69, 72, 80, 92; Bessemer, 55, 55, 56, 59, 58, 58, 58, 59, 68, 72, 80, 95; Thomas, 46, 46, 47, 47, 47, 48, 48, 53, 58, 62, 69, 78; foundry No. 1, 61, 61, 63, 63, 64, 66, 66, 68, 72, 75, 85, 101.

HIGH PRICES FOR SALT.—The salt syndicate of Rhineland, Westphalia, and Alsace-Lorraine has advanced the price of salt 40 pfennigs (4¾d.) per sack.

COLLIERY COMPANIES.—The owners of collieries are taking advantage of the present state of the coal market to sell their properties to share companies. Several such companies are now being floated in this district. Changes of this sort must affect in an important degree the future of the coal mining industry.

LILLE, 7TH JANUARY, 1890.

IRON.—Though nominally bars are quoted 144s., few if any transactions take place at that price. The current rates are from 148s. to 152s. a ton, and the market is firm at that level. It is long since manufacturers' order books have been so well filled as they are now. In all cases there is work in hand for at least four months to come. A serious retardation of the production of the iron and steel works is, however, caused by the short supply of coal. Most works are running short time from this cause, and as there are no stocks at the pits the prospect is disquieting.

TEXTILE MANUFACTURES.—Brisk business at this season is not to be expected, but the turnover in linen goods in the last week is in some degree disappointing, inasmuch as it compares unfavourably with that of the corresponding week of last year. There are, however, plenty of indications of greater activity after the middle of the current month. The reports last to hand from Roubaix describe the situation of the woollen goods trade as exceptionally good, and manufacturers begin the year with bright prospects. The Calais tulle industry continues in a languid state, but the spring trade is expected to be good. Those who are in the best position to form a sound judgment regard the future with confidence.

COTTON AND JUTE.—The Customs returns indicate greater manufacturing activity in the cotton and the jute industries in 1889 than in the previous year. The declared value of the raw cotton imported in the first eleven months of 1889 amounted to £6,370,200, against £5,651,480 in

Digitized by Google

1888. That of raw jute for the same periods is recorded in the returns as £833,840, against £649,040. The jute market is now very active, and exhibits a tendency to yet more vigorous life.

AMSTERDAM, 6TH JANUARY, 1890.

THE LABOUR QUESTION.—The first Chamber of the States-General will shortly discuss the Government proposal to prolong the inquiry by Royal Commission into the state of the working clssses in Holland, preparatory to special legislation on the subject. Upon the whole, the proposal has been well received by a Grand Committee of the House, although several members doubted the wisdom of making special legislation for the labouring classes, seeing that the evils complained of are not to be cured in that way. Others remarked that, if special legislation to benefit the working classes were the outcome of the proposed continued inquiry, it would be necessary also to pass an Act for the special protection of employers against the combination of workmen. Some members deplored the exclusion of field labour from the scope of the Commission's inquiry, although they knew that the Royal Commission on Agriculture is already inquiring into that class of work.

THE NEW WATERWAY AT ROTTERDAM.—In the year 1889, 4,271 steamers and 567 sailing vessels entered the new waterway at the Hock van Holland, whilst 4,246 steamers aud 563 sailing vessels were cleared outwards. This does not include fishing craft nor foreign tugs.

THE NORTH SEA CANAL.—During the past year 210 sailing vessels and 1,363 steamers entered Amsterdam from foreign ports, against 213 sailing vessels and 1,353 steamers in 1888.

NEW WATERWORKS FOR AMSTERDAM.—The summer season of 1889 was remarkable in the Dutch capital for its dearth of water for domestic purposes. This water is brought into town from the dunes around Haarlem, by a company, which, partly with English capital, started in 1855, and has been extending its reservoirs and water-pipes ever since, in order to keep pace with the wants of a city that has doubled the number of its inhabitants in the last twenty-five or thirty years. The company has a monopoly, in virtue of an exclusive concession, but its charter is now very stringent, and, when the water supply failed in the summer, and the management could give no satisfactory explanation, a committee of experts was appointed to make inquiry and report to the urban authorities. The committee has just issued its report. It finds that the company has not complied with the terms of its charter, that the collecting of water in the dunes is defective, because the pipes are not laid at a level to ensure the proper interception of all the available water; and, further, the committee states that the conduits between the dunes and Amsterdam are insufficient to carry all the water required, and that the proper supply has been kept down by the Hill Water Company by using a low pressure in the dunes. The committee proposes certain provisional measures, which will cost some £15,000, and which will tend to increase the water supply of Amsterdam. The report, however, points out that permanent measures are necessary, that the Hill Water Company must be compelled to carry out its contract in accordance with the concession, and that such cannot be done without giving the town authorities of Amsterdam the power to control the necessary pressure in the dunes, and see that it is maintained.

CO-OPERATIVE MARINE INSURANCE.—Four leading Dutch steamship companies have combined in the formation of a co-operative marine insurance fund, out of which all losses arising at sea for any of them shall hereafter be made good. This decision has been come to after the serious disasters that have befallen our steamboat undertakings lately, the Netherland American and the West Indian Steamship Companies both losing their finest vessels, almost simultaneously, by collisions in the Channel. These losses have proved very heavy. The former undertaking has since replaced the "Leerdam," gone down, by purchasing the steel-built steamship "Arabic" of the Oceanic Steam Navigation Company, Limited, in Liverpool. She was constructed in the year 1881, at Harland & Wolff's, in Belfast. Her future name will be "Spaarndam," and she is intended for the North American mail service.

METHYL SACCHARINE.—What is methyl saccharine? The Dutch Government does not pretend to know the secret of its manufacture. It only knows that it resembles saccharine, and that its sweetening powers are even greater. Consequently the Minister of Finance has drawn the attention of his Custom-house officers to the existence of methyl saccharine, and given instructions to tax its import as a drug or spice, with an *ad valorem* duty of 5 per cent., keeping a strict watch on the quantities imported, and noting the country it comes from, the makers, and the names of the senders and addressees.

TELEPHONIC COMMUNICATION IN HOLLAND.—In the course of the month the Dutch Bell Telephone Company will give a great extension to the system in different provinces after laying special new lines between Amsterdam and Haarlem, Amsterdam and Zaandam, Rotterdam and Dordrecht, &c., in accordance with the Government regulations regarding their construction. After the completion of these supplementary lines, towns not hitherto in telephonic communication will be brought into direct contact, and Dordrecht will be able to converse with Haarlem, and Zaandam with Rotterdam and the Hague. The uniform charge for the use of these telephones is to be 50 Dutch cents, or 10d., for three minutes' talk on the instrument.

TELEPHONES AT AMSTERDAM.—On the 1st of January 1888 the telephonic system at Amsterdam had 1,490 subscribers, against 1,368 on the 1st of January, 1889. About 53,500 communications were booked there in the past year, and 41,000 telegrams forwarded by telephone.

TELEGRAPHS AT AMSTERDAM.—In 1889 the chief telegraph office at Amsterdam received and forwarded 412,343 messages, delivered 523,219 messages, retransmitted 1,633,655 messages, whilst 393,751 messages went, viâ Amsterdam, from England to Germany and from Germany to England. Fourteen sub-offices treated 438,445 messages besides.

OMNIBUS WAR AT AMSTERDAM.—The two rival omnibus and tram companies of Amsterdam are now waging an open war. The public is the gainer, as the price of tickets has fallen to a little over a penny for any distance in town, including a change of cars, as in Paris; but those that do not buy their tickets beforehand have to pay 2½d. in cash.

COPENHAGEN, 4TH JANUARY, 1890.

PUBLIC WORKS IN SWEDEN.—The Department for Roads, &c., in Sweden will soon have been in existence for fifty years. Several interesting particulars about its work have recently appeared. On new roads they have expended about £1,000,000 in wages, and no less than 878 different roads have thus been made or improved. The area of land reclaimed or otherwise improved amounts to 302,738 hectares, divided into 1,102 different undertakings, and entailing a cost of labour of £1,100,000. Of other land, arable or forests, 28,081 hectares have been treated, at a calculated cost of £300,000. During the same period 58 bridges have been built and 21 canals have been made, as well as 88 harbour works, 7 docks, and one river extension for the floating down of timber.

ELECTRICITY AND GAS.—The question of gas and electric light in Stockholm has now advanced another step, inasmuch as the Corporation, without the slightest hesitation, have voted the two grants for £30,000 each for the commencement of a new gasworks and a new electric central station. In Gothenburg a large new gasworks is in the course of erection; the calculated cost is £50,000.

ICE BREAKING STEAMERS.—Ice breaking steamers are coming into extensive use. The Motala Engineering Company, Sweden, has received a new order from the Aalborg harbour authorities, Denmark, for an ice breaker to be used over the Limfjord. She is to be 90ft. long, 19½ft. broad, and 8ft. deep, and the engines are to indicate 260 h.p. She is to be fitted with powerful pumps, &c., so that she can be used also for tug and salvage service. The same firm have just secured another order for a 1,400 tons cargo steamer from Messrs. Anderson & Lindholm, Gothenburg. She is to have triple expansion engines, and will be built of Motala plates.

SWEDISH BREWERIES.—The Stockholm Brewery, St. Erik, which has been much coveted both by English and German capitalists, has now passed into the possession of a Swedish company, Svenska Brijggeriaktiebolaget. The selling price is 4,050,000kr., but this does not include outstanding accounts, &c. In Copenhagen an amalgamation of a number of breweries is understood to be under contemplation, and the shares of the less successful ones have accordingly improved somewhat in their quotation. Nothing reliable has, however, transpired, and there would no doubt be several difficulties in the way of completing the plan in its full extent, the more so as the majority of Danish breweries are doing very well.

DANISH BREWERIES.—Danish breweries vary greatly as to their financial results. While some do exceedingly well, others are by no means in such flourishing condition. The Marstrands Breweries, Copenhagen, held their annual meeting a week or two ago, when no dividend was declared. The expenditure for coal and other raw materials was about 60,000kr. in excess of the previous year, and the sale of "Bavarian beer" considerably smaller. Export had taken place to Brazil and the Argentine Republic. The gross profits amounted to 170,573kr., besides 8,343kr. for rents, but after deducting the various expenses, only a balance of 2,787kr. was left, which was carried forward to next year's account. As a somewhat larger balance had been carried forward from the previous year, the last year has given an actual loss.

TEXTILE INDUSTRIES IN SWEDEN.—A large new manufactory for zephyr and tricot wools is approaching completion at Boras, Sweden. It is, to a great extent, built on the German system. The main hall is 44ft. long and 35ft. broad. The chimney is 152ft. high. The special machinery is from the German firm of N. Schumberger & Co. The manufactory is the first of its kind in Sweden, and belongs to the Göta Company,

LAND RECLAMATION. — Another land reclamation scheme is contemplated in connection with the Helgea River, Sweden, where 4,000 hectares of land will be drained through the medium of extensive dams, pumpings, and dredgings. This will probably necessitate the Helgea River being made deeper for a distance of some 34 kilometres, and a committee has been formed for the purpose of thoroughly investigating the matter.

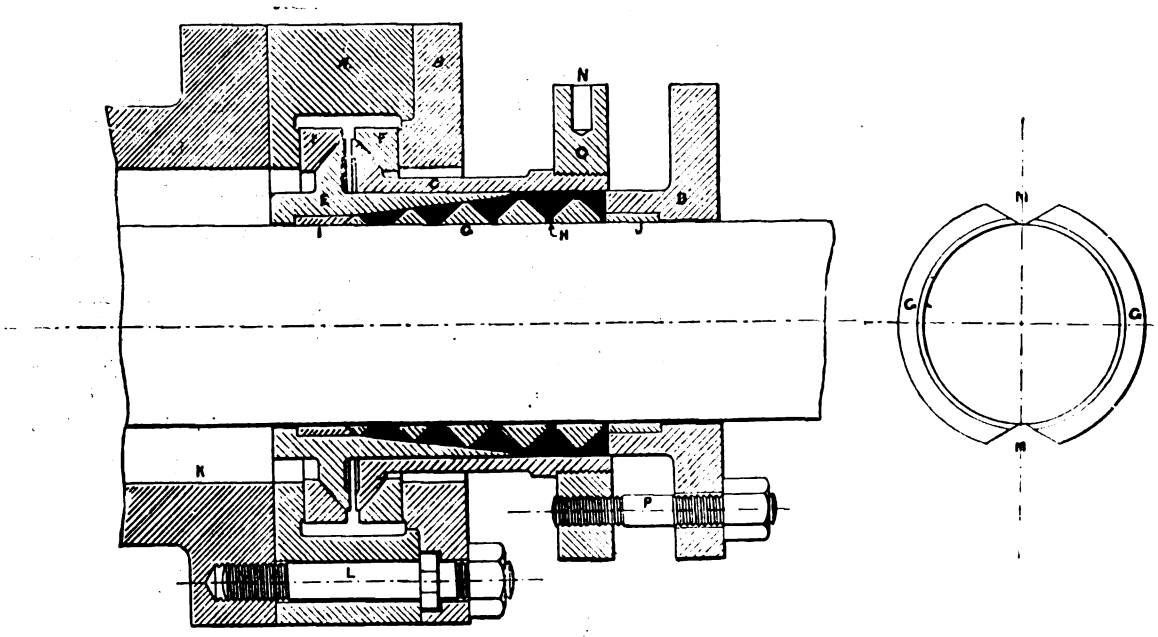
THE COPENHAGEN WATERWORKS.—These works are about to be considerably extended, and tenders for the machinery, engines, boilers, pumps, &c., were invited some time ago. Danish engineering circles have naturally been considerably interested in the result of this competition, and general satisfaction is evinced at the bulk of the large orders going to the leading Danish engineering establishment—viz., Burmeister & Wain's Engineering and Shipbuilding Company, Copenhagen. This firm has secured the order for all engines, &c., in spite of severe competition from several large foreign firms. The firm of Babcock & Wilcox have got the order for the boilers, no Danish firm being in a position to comply with the conditions of the tenders in this respect.

NEW YORK, 27TH DECEMBER, 1889.

THE COAL MARKET.—There has been no improvement in the anthracite coal trade. The yards are full of coal and the weather is as mild as spring, so that there is little prospect of improvement. The situation is gloomier than at any time this winter. The Reading Company, after holding out as long as possible, has been forced to work only three-quarter time. A discouraged feeling pervades official circles, and predictions of worse times are heard among the less enthusiastic. Among the dealers the situation is about the same. There are few orders and no immediate prospect of more. Shipments to the East are small, and those to the West are no better. The only demand anywhere in the trade is for furnace and steam coal, and notices that these grades are to be advanced in price have caused large consumers to put in big orders ahead.

THE IRON AND STEEL MARKETS.—The iron trade is in about as good a condition as could be desired. Prices continue firm, with indications towards higher prices; the demand is fully up to the supply, and all the concerns have as many orders on hand as they care to book. There is no definite opinion as to the probable course of the market, and each firm engaged in the business seems to be acting on their own opinion as to the future of the trade. If the present demand continues, prices are pretty sure to advance, as the cost of materials has been steadily advancing. The general course of action seems to be to buy what is needed, or sell what is ready for the market, but to place or take no orders that would place the operator at a disadvantage on a sudden change of the market either way. The pig iron market is strong, with prices practically the same as for the last three weeks. The demand for foundry purposes is not quite so heavy, and millowners are pretty well supplied for the present, but there are still some heavy orders to be placed that sellers do not care particularly for unless at high figures. In manufactured iron but little business has been entered during the past couple of weeks. This does not mean that the demand has fallen off, but that sellers are inclined to ask higher prices than buyers are willing to pay unless they are satisfied they cannot to better. All early needs seem to be provided for, and the market is a waiting one. Bars are steadier, and prices are 1·95c. per lb. in carload lots. Plates are firmer, but not much in the way of orders have been booked. Prices are 2·3c. for iron and 2·5c. for steel. Steel rails are firm at $35 per ton at mill for large lots, and $36 for smaller ones. Sales for delivery during 1890 amount now to about 750,000 tons. There is a good demand for billets, with sales at about $37 per ton.

STEEL SHIPS ON THE LAKES.—The project of a great shipbuilding industry on the banks of the Calamut has at last taken definite shape, notwithstanding the denials of the officials of the Illinois Steel Company that they had in contemplation such a project. The Globe Iron Works of Cleveland, Ohio, the most extensive builders of steel ships on the great lakes, have joined hands with the Illinois Steel Company in the organisation of a company to build steel ships in Chicago. The new corporation is to be known as the Chicago Shipbuilding Company, and six steel steamers will be on the stocks in its yards within a few months. The yards will be on the east side of the Calamut river in South Chicago. It is not intended to put in boiler and machine shops immediately, but this will be done before long, as also a dry dock.



ALASKA SEAL FISHERIES.—Secretary Windom has decided not to renew the lease of the Alaska Commercial Company of San Francisco, which has had the monopoly of the Alaska seal fisheries for twenty years. The Secretary has taken steps to give any responsible bidders an opportunity to obtain the lease, and will advertise for bids. The advertisements will be issued in a few days, after the form of contract is made up and approved. It will be substantially the same as that under which the present lessees have been operating, there being a limit as to the number of seals which can be killed during the season.

SUGAR.—Offerings of raw sugars have been greater than current needs, and prices have ruled easy in consequence. Refined is quiet and ⅛c. lower per pound. The report that the sugar trust has prepared to transfer its assets to a new corporation if the Court of Appeals pronounces the trust illegal seems to mean that it will take advantage of the charter of the Commonwealth Refining Company, of Hartford, which is broad enough to cover any sort of business the trust might want to engage in. This company has the right to own and conduct sugar factories and refineries, and to transact business of all kinds appertaining to sugar, including the "holding of stock of corporations having relating to sugar refining for parties interested therein, with all the rights of owners, and certificates of interest therein to issue to parties entitled thereto, and to acquire, purchase, receive, in trust or otherwise; hold, grant, sell, mortgage, lease, and otherwise dispose of all kinds of property, real, personal and mixed, whether in the State of Connecticut or elsewhere."

IMPROVED "UNIVERSAL" STUFFING BOX.

CONSTRUCTED BY MESSRS. J. & E. WOOD, ENGINEERS, BOLTON.

LONGITUDINAL SECTION. END VIEW OF RING.

THE PROGRESS OF THE MANCHESTER SHIP CANAL DURING 1889.

THE progress of the construction of this great work during the last twelve months has been very marked, and it bears ample testimony of the indomitable energy, perseverance, and practically illimitable resources of the eminent contractor whose death it was our painful duty to record a few weeks ago. Throughout the whole length of the works—35 miles in extent—everything is in a very forward state; and, while the contractor has been vigorously pushing forward the work, he has not been unmindful of the needs and comforts of his men; for along the line of work places of worship, reading and recreation rooms, hospitals, stores, &c., have been erected for the special use of the men and their families.

The amount of plant has been considerably increased during the last twelvemonth, and now consists of 163 locomotives, nearly 6,000 waggons, 96 steam navvies of English, French, and German make, 148 steam cranes, 250 pumping and other engines, and about 34 steam pile drivers; about 210 miles of temporary railway have been laid, and there are over 12,000 men and boys, and 180 horses employed upon the works. In addition to the above, concrete mixing machines are used for the formation of the concrete walls of the various lock pits, the machines being Carey & Latham's patent, made by Messrs. J. H. Wilson & Co., Sandhills, Liverpool, each machine being capable of mixing 20 cubic yards of concrete per hour.

The work on No. 1 section, from Eastham to Ellesmere Port, has made rapid progress, and the locks and the lock gates are very far advanced; a shed 200ft. long has been erected for the construction of the latter and lighted with electric light. There will be three locks at Eastham, one 600ft. by 80ft., one 350ft. by 50ft., and a small one next the river 150ft. by 30ft. In addition to the ordinary lock gates, storm gates will be provided. All the gates are made of greenheart. A very heavy cutting through the red sandstone has been made on this section, and where the stone was sound it was carefully quarried and used on various portions of the works. A large pumping engine has been at work on the lock pit excavation, and is one that was used on the Severn Tunnel works; the cylinder is 60in. diameter and has a stroke of 9ft., and actuates a pump 31in. diameter capable of lifting 300 gallons per stroke to a height of 85ft. In section No. 2, from Ellesmere Port to Ince, there is another very heavy cutting made through the red sandstone, which provides a much harder stone than that found in No. 1 section; the cutting is also the deepest in the whole length of the canal. An interesting feature in the Eastham section is the wall across Port Hall Bay, about one mile in length, and which has been the cause of litigation between the Mersey Docks and Harbour Board and the Ship Canal Company. According to the provisions of the Act it is necessary to have a number of openings left in the bank to enable the tidal water to flow in and out of the enclosed portion of the estuary during construction. The contractor, however—no doubt with the object of facilitating the construction of the bank and of the excavation for the canal inside—made the bank continuous, and so kept out the water. An injunction was applied for in the Court of Chancery to restrain the contractors from making a continuous bank, and after a long hearing it was granted. Still the opening was not made, and the Dock Board have again applied to the Court. The Ship Canal Company have also applied to Parliament for further powers to alter the construction of the works. It appears, therefore, likely that the important and interesting question of the *régime* of the estuary will be again fought out in the committee room. The piling across the foreshore from Stanlow Point to past the entrance to the port, a length of more than a mile, is steadily progressing. The important work of constructing the syphon to conduct the Gowy under the canal has been a difficult undertaking, and is now well advanced. The syphon consists of iron pipes 12ft diameter. In Section No. 3, from Ince to Weston Point, the important sluice works for regulating the waters of the River Weaver are far advanced, and consist of ten sluices having an opening of 30ft. width each. All the steel piers for carrying the sluice gates are erected, and the latter are now being riveted up. At Weston Marsh lock the fender course is being put in, and the excavations on the north side are making rapid progress. Over 1,300 permanent piles have been driven at Weston Point during the last nine months. In Section No. 4, from Weston Point to Norton, the progress of the work has not been so marked as in the other sections. A railway has been laid in the cutting for the convenience of the traffic to Messrs. Wigg Bros. & Steele's works—which was formerly carried on the Runcorn and Latchford Canal—so that this canal will no longer interfere with the construction of the work. A small portion of the concreting of the sea wall has been done, but the works on the Widnes side of the river have been stopped. At the Old Quay the work at the tidal openings is steadily progressing. In Section No. 5, from Norton to Latchford, the cuttings have proceeded satisfactorily, and a large quantity of stone is obtained from the Lower Walton and Acton Grange cuttings. The excavation of the Grappenhall Road, close to Latchford station, has commenced, and a substantial temporary bridge spans the cutting. In Section No. 6, from Latchford to Warburton, the point of interest is the Latchford locks and sluices, where the work is progressing rapidly. The pier foundations of the bridges to carry the London and North Western Railway deviation are nearly completed; the stone for these piers is obtained from a quarry near Chester, and is a light-coloured sandstone. The bridge over Bradshaw's Lane is completed, and several other road bridges are far advanced. Most of the canal in this section has been excavated its entire width and depth. Section No. 7, from Warburton to Barton, is in a forward state; the lock walls at Irlam are rising gradually, and the cutting of the canal is proceeding rapidly. The piers for the railway deviation bridges at Irlam and at Cadishead are in an advanced stage, some of them being several feet above the ground. The Warburton cutting passing through the Keuper marls is of interest to geologists, and was the scene of a disastrous landslip early in the year. Section No. 8, from Barton to Mode Wheel, is an important one, and the Barton locks on Sticken's Island are progressing rapidly. Near Hulme's lock a temporary river diversion is being made during the cutting of the canal through the site of the lock; when the cutting is completed the water will run in the old channel, and the diversion filled up. At Salteye the pitching of the banks has proceeded slowly, and the south bank of the river has been strengthened with piles. Most of the cutting is completed, and interest is centred upon the construction of the new bridges to replace the Barton and other bridges. Section No. 9, the terminal section, contains some of the most important works in the whole undertaking, and all of them are in a very forward state. The Mode Wheel locks are far advanced, and the Salford and Pomona Docks are so far ahead that the granite coping is being laid on some lengths of one of the docks which has been nearly excavated to its full depth—the excavations being made after the construction of the wall. A coffer dam is being constructed in the river at the entrance to the Pomona Docks. A large shed has been erected at Salford, in which the dock gates are constructed, and one large pair is nearly completed. The swing bridges which cross the canal at various points are in hand, and are being constructed by Messrs. Arrol Bros., of Glasgow.

The work from beginning to end is being pushed forward rapidly, and it appears very probable that it will be completed within the specified time, and the universal opinion of competent authorities is that the work is also being well and substantially done.

IMPROVED "UNIVERSAL" STUFFING BOX.

OUR illustration shows a cylinder stuffing box made by Messrs. J. & E. Wood, engineers, Bolton, the main feature of which is the perfect freedom which is given to the body of the box to adjust itself while at the same allowing no escape of steam. The construction is as follows:—The cast iron box A is bolted to the cylinder cover K, the joint being made by cement in the ordinary way. The cylindrical case or box C is formed with a ring at its lower end, the upper edge of which is bevelled to correspond with the upper ring F. An inner case E is similarly formed with a bevel surface engaging with the lower ring F. The cover B is used to keep the rings in position, and their surfaces, which are in contact respectively with those of A, B, C, and E, are ground to a steam-tight fit. It should be specially noted that the cases C and E, although fitting each other, are distinct, and it will be easy to see how important this is. The inner surface of E is tapered as shown, so that as the packing is pushed downwards the wear is taken up until the rings are quite worn away. The effect of screwing up the gland D is twofold. It tends, by the pressure put upon the packing, to push E upon its seat on F, while, in consequence of the upward pull on the case C, it is in like manner drawn on to its seat on F. As a corollary, the rings F are pressed on to their seats on A and B. It follows that a perfect joint is made without the use of any springs, which in such a situation must be objectionable. All these results are obtained without destroying the freedom of movement of the box, which can adjust itself as required. It is, indeed, found that in most cases the box has, during the working of the engine, a slow rotary motion round the rod, thus leading to an even wear of the packing. We inspected one of these boxes which had been in work for two years on an engine making 85 revolutions per minute, the piston rod being 3½in. diameter, and it was quite tight, although during work it was slowly rotating.

SHIPBUILDING NOTES.

ON the 24th ult. Messrs. Harland & Wolff, Limited, Belfast, launched a steel screw steamer, named "Gaekwar," for Messrs. Thomas & John Brocklebank, Liverpool. This vessel is a sister ship of the "Ameer," launched by the same firm in August last, and, like her, is intended for the Eastern trade. Her dimensions are: Length, 400ft.; breadth, 45ft.; gross tonnage, 4,014 tons. The boilers and engines, which are triple expansion of 1,600 h p., are being built by the same firm, and the vessel is expected to be ready for sea early in the new year.

ON the 27th ult. Messrs. Scott & Co., Bowling, launched the s.s. "Sard." The vessel was built to the order of Mr. Wm. Robertson, Glasgow, and was supplied with engines by Messrs. Muir & Houston, Harbour Engine Works, Kinning Park, Glasgow. The engines are of the triple expansion type, with cylinders 13in., 21½in. by 34in., by 27in. stroke. The

Digitized by Google

"Sard" went on her trial trip on the 28th, when she attained a mean speed of 11¼ knots, which was considered highly satisfactory.

On the 30th ult. the "Abbotshall," built by Messrs. Jno. Scott & Co., Kinghorn, went on her trial trip. On a trial of speed; she accomplished 13 knots an hour, or a knot more than was expected. The "Abbotshall" was built for the Kirkaldy and London Steam Shipping Company.

TRIPLE EXPANSION ENGINES OF THE S.S. "FRIESLAND."

In *Industries*, Vol. VI. (19th July, 1889), we illustrated in a two-page supplement the triple expansion engines of the s.s. "Friesland," which was built and engined by Messrs. James & George Thomson, Clyde Bank, for the Red Star Line, and now we give an end view of the same engines. The diameters of the cylinders are respectively 35½in., 56in., and 89in., and the stroke is 4ft. 6in. We shall give further particulars, with the results of trials, in an early issue.

Notices of Meetings.

NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, January 14th, 8 p.m. Paper to be read: "Recent Dock Extensions at Liverpool," by George Fosbery Lyster, M.Inst.C.E.

INSTITUTE OF MARINE ENGINEERS.—Monday, January 13th, 7.30 p.m. Paper to be read: "The Marine Engine Considered as a Machine," by Mr. J. G. Hawthorn.

UNIVERSITY COLLEGE, GOWER STREET, LONDON, W.C. Wednesday, January 15th, 8 p.m. Dr. W. S. Squire, on "Some Considerations in Connection with the Economical Use of Fuel."

ROYAL METEOROLOGICAL SOCIETY.—Wednesday, January 15th, 7.15 p.m. Annual General Meeting. Dr. W. Marcet, F.R.S., will deliver an Address on "Atmospheric Dust."

PHYSICAL SOCIETY.—Friday, January 17th, 5 p.m. Papers to be read: "On a Carbon Deposit in a Blake Telephone Transmitter," by F. B. Hawes; "On Electric Splashes," by Prof. S. P. Thompson, D.Sc.; "On Galvanometers," by Prof. W. E. Ayrton, F.R.S., T. Mather, and W. E. Sumpner.

SOCIETY OF ARTS.—Wednesday, January 15th, 8 p.m. Adjourned discussion on Sir Robert Rawlinson's paper on "London Sewerage and Sewage." Friday, January 17th, 5 p.m. "The India Office Records." By F. C. Danvers.

PRICES CURRENT, 8TH JANUARY, 1890.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: Stocks of copper decreased but slightly during the second half of December, which was doubtless owing to the holiday period and the stock-taking at the end of the year.

The total visible supply on Dec. 15th was	.....	99,156 tons.
" " " 31st	.....	98,847 "
Decrease for second fortnight	.....	309 "

Chili bars have been very firm since the beginning of the year, and the high rates paid for three months' metal indicate firmness in the future. On the opening day, the 2nd inst., quotations were £50 15s. to £51 for cash, and £50 12s. 6d. to £51 for three months. To-day's prices are £51 10s. to £52 for cash, and £51 15s. to £52 2s. 6d. for three months. The Rio Tinto Company advanced their price for ingot copper £2 per ton yesterday. Manufactured is very firm at £66 to £67 sheets, and £69 to £70 bottoms.

TIN: Somewhat unsettled, with only moderate business doing.

LEAD has improved steadily during the week, and promises to be considerably dearer again, as there is not much offering.

SPELTER: Considerably firmer, with a good demand. Some of the Continental firms are unable to quote, being fully sold. There is a strong market, with every probability of higher prices.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—The new year has opened under very favourable conditions in the chemical trade, most articles being in good demand, and prices firm. In the alkali branch matters have considerably improved since the opening of the year. Bleaching powder is dearer, some of the larger makers holding off the market. Caustic soda of all grades is scarce at much higher prices, and soda ash also has advanced. Soda crystals steady. Acetates of lime are again dearer, and tending further upwards. Sulphate of copper is scarce on spot. Yellow prussiate of potash advanced to 10½d. Epsom salts advanced 5s. per ton. A good business is being done in recovered sulphur. Liquid carbolic is rather more active, but crystals continue flat.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, Jan. 9.—*Coal.*—An agent of the Belgian Government is in the Pas-de-Calais district, buying coal for the State Railways. German consumers are buying largely of French coal. Several heavy trains, laden with French coal for German customers, have passed through Charleroi within the last two or three days.

Iron.—Some of the merchants have advanced the price of bars and joists to 176s., but the large firms do not appear disposed to follow. In the Nord the price has risen to 158s. The markets everywhere are active; but sellers are cautious, fears being entertained of a dearth of coal. Already many works in the Haute Marne and the Meurthe-et-Moselle are greatly hindered in their production. The demand for wire is brisk.

Metals.—The metal market is buoyant all round. Copper has further risen in price, Chili bars being £54 10s., and best selected £60. Tin has recovered the loss recorded last week. Banca is quoted £108, and Straits £103. Lead is active, and has advanced to £14 12s. delivered at Havre. Spelter continues its upward movement. Silesian is quoted £26 Havre.

BERLIN, Jan. 9.—*Bourse.*—Industrial securities are somewhat flat to-day, sellers predominating. The uncertainty arising out of the doubtful attitude of the coal miners has made investors cautious, and speculators have turned the circumstance to account to "bear" the market.

Jute Industry.—The market for jute goods is very active, and the animation tends to increase. Prices are steadily rising. As the demand is likely to be heavier next month, still higher prices may be expected. Jute yarns are much sought after, the supply being short of the demand.

BRESLAU, Jan. 9.—*Coal.*—Since January 1st the prices of coal have been advanced 1s. a ton at the pits, and from 2s. to 3s. for the household sorts delivered by the merchants. Production is far below the demand. The short supply is affecting injuriously the industries of this locality. A large proportion of the output of the Silesian pits is being exported to Austria.

Iron.—There is a strong and steady current of business in iron. The supply of pig falls short of the demand. Prices are unaltered, and for the first business week of the new year are as follows: Good forge pig, 75s. to 80s.; foundry, 80s. to 85s.; bars, 190s.; profile iron, 200s. to 210s.; boiler plates, 235s. to 240s.; thin sheets, 240s. a ton. The demand for finished iron and steel is brisk for all classes. Export business with Russia and Austria-Hungary is increasing.

Zinc.—The zinc market is very active, and prices are firm for delivery in the first quarter of the year. For later delivery slightly lower prices are accepted. Spelter of the W. H. brand is quoted £25; ordinary sorts, £24 for February and £23 12s. for the second quarter.

CHARLEROI, Jan. 9.—*Coal.*—The number of colliers now on strike is officially declared to be about 19,500. Industry is paralysed. Iron works and glass works are partially stopped for want of fuel. The railways are without coal. Agents have been sent into France, Germany, and England to buy coal and coke for immediate delivery. The situation is rapidly becoming serious.

Iron.—The market is greatly disturbed by the colliers' strike. Manufacturers are refusing fresh orders till the situation becomes clearer. Most of the business being done is in ships' plates for export to England and Russia. Ordinary forge pig is quoted 72s. to 75s.; Longwy forge is being sold at 70s. delivered; No. 2 bars are firm at 152s.; joists are quoted 144s. at works and 148s. f.o.b. Antwerp; ships' angles are 158s.; No. 2 plates, 176s.; steel plates, 208s.; and steel rails f.o.b. Antwerp, 140s.

HOME INDUSTRIES.

LONDON 9th January, 1890.

The Money Market.—Though the outside market has got a fuller supply of loanable money at its command than last week, the money market continues very tight. Rates for loans and discounts have been maintained, there being less disposition on the part of Continental bill brokers to discount bills at lower rates than those exacted by London brokers. As this competition has largely tended to render ineffective the precautionary measures taken by the Bank to preserve its reserve, the cessation of it is a welcome feature. The state of the money market has taken all the spirit out of the Stock Exchange, and prices have fallen all round. Consols and home railways are always adversely affected by scarcity and dearness of money, and the other departments, though less sensitive to this influence, have had other troubles to contend with. American railways have been a rather shaky market, and the announcement of a short dividend on the First Income Bonds of the Philadelphia and Reading Railway, pulled down the whole American list. Canadian Pacifics have been in fair request, but Grand Trunks and the Mexican Railway's securities have had a further fall, the traffic returns still being unfavourable. Foreign shares have not been in request, but copper shares have been bought freely.

Companies.—The following companies have been registered since our last report:—Salter & Co., Ld., with a capital of £21,100, to carry on the business of brewers and maltsters; The Automatic Tap Syndicate, Ld., with a capital of £2,000, to acquire a certain patent; The Mount Morgan Gold Mining Co., Ld., with a capital of £10,000; Cooper's Patent Glass-lined Metal Piping Co., Ld., with a capital of £15,000; Cochrane & Co., Ld., with a capital of £350,000, to conduct the business of colliery proprietors, miners, &c.; Strout's Brewery Co., Ld., with a capital of £80,000, to carry on business as brewers; Ralphs & Preston, Ld., with a capital of £15,000, to carry on the business of engineers and machinists; The African General Exploring Co., Ld., with a capital of £20,000, to carry on mining operations; Ellis, Drew, & Co, Ld., with a capital of £10,000, to carry on business as brewers, &c.; The Atlantic Steam Shipping Co., Ld., with a capital of £100,000; The Golden Leaf, Ld., with a capital of £350,000, to acquire lands and mining rights, &c.; The Gold Koppe Mining Co., Ld., with a capital of £333,007, to acquire mining rights in Austria; The Electrical Standardising, Testing, and Training Institute, Ld., with a capital of £10,000, to establish institutions where electric instruments can be tested.

Hemp.—In Baltic hemp the spot business is slow, and consists mostly of retail transactions. There has been a better inquiry for arrival, but business is checked by the firmness of shippers. The Italian markets are very strong, and there appears to be no prospect of any reaction at present. The week's transactions have consequently been very small. Since the new year the demand for Manilla hemp has improved, but very little business has been done yet.

Shipping.—During the past fortnight freights have been inactive, with the exception of American. The holidays have been more general and longer in extent than before. Coal prices have further advanced, and quotations are difficult to obtain at all. Prices of steamers are firm, and good second-hand tonnage meets with a fair sale.

Institution of Mechanical Engineers.—The forty-third annual general meeting of this institution will be held on Wednesday, Thursday, and Friday, the 29th, 30th, and 31st inst. In addition to the ordinary routine business, Mr. Joseph Tomlinson will be elected president in place of Mr. Charles Cochrane, and the following papers will be read:—"On the Compounding of Locomotives Burning Petroleum Refuse in Russia," by Mr. Thos. Urquhart; "On the Burning of Colonial Coal in the Locomotives of the Cape Government Railways," by Mr. Michael Stephens; and "On the Mechanical Appliances Employed in the Manufacture and Storage of Oxygen," by Mr. K. S. Murray.

The Institution of Civil Engineers.—The seventy-second anniversary of the Institution of Civil Engineers occurred on the 2nd inst., when a revised list of the members of all classes showed that the numbers now on the books amounted to 5,804, representing an increase of 3¼ per cent. in the past twelve months.

Blocking Orders.—The attention of the electrical section of the London Chamber of Commerce has been called to the fact that many of the notices which have been given by the local authorities of their intention to apply for provisional orders have been done with a view of blocking the extension of electric lighting owing to gas interests or other causes. The matter will be brought forward at the meeting of the section on the 28th inst., and it is hoped that corroborative evidence will be communicated to Mr. Trotter, the correspondent, with as many details as possible.

Electric Lighting in St. Pancras.—The St. Pancras Vestry held a special meeting on the 1st inst., to consider the unanimous recommendation of its Lighting Committee to carry out an installation of electric lighting under their provisional order obtained in 1883. The vestry, by a large majority, adopted the recommendation, and instructed their engineer, Prof. Henry Robinson, to prepare the necessary plans and specifications for a first installation of 10,000 private lights and 90 public lights, involving an outlay of about £60,000.

Brush Electrical Engineering Company.—The chairman and directors of the Brush Electrical Engineering Company celebrated the tenth year of a prosperous existence by inviting the leading electrical engineers to dinner at the Hôtel Métropôle on Monday night. About a hundred and fifty guests, representing all branches of the industry, and including most of the company's more formidable trade rivals, joined in well-wishes to the continued success of the company. Lord Thurlow, the chairman, proposed the conventional toasts, and succumbed to the temptation which no electrician has ever been known to resist, and "talked shop" even in connection with her Majesty. Speeches were also made by Sir F. Bramwell, Viscount Bury, Mr. J. S. Sellon, Sir F. Abel, and Sir J. Pender.

MANCHESTER, 9th January, 1890.

The Iron Trade.—There is an extremely strong feeling still pervading the iron market, and the free buying which was expected is actually going on. Makers are comparatively indifferent as to orders, and in some cases, especially in hematites, good brands are almost unobtainable. The price of pig iron ranges from 3s. to 5s. per ton over the quoted prices for warrants, which are very deceptive as a guide to actual values. Although the quarterly meetings take place this week, many merchants and consumers have anticipated them, and have placed their contracts already. This course has been pursued because it was felt that much more satisfactory arrangements could be made than is possible amidst the excitement of the actual meetings. Bar iron is very firm in all qualities, and is very bad to buy. The price for local bars is not less than £8 10s. per ton, and one large transaction has been concluded for Yorkshire bars at £9 2s. 6d., delivered Leeds. These prices are, it is anticipated, likely to be almost at once increased, and buyers are very anxious to purchase. There is a large trade being done in other metals, such as copper and brass, and full rates are obtained. The volume of business at this time of the year is remarkable, and has not been exceeded.

The Engineering Trades.—There is a very buoyant feeling among engineers in this district. Not only have they ample work booked, but there is a large volume of fresh business being offered. Stationary engine builders are full of work, and although there are not many new large jobs being offered for the home market, there are several being negotiated for India and the Continent. Boilermakers are full of work, and are very stiff in their prices, the quotations for boiler plates being very much firmer. Locomotive engineers are busy, as are also machine tool makers, who are mostly working overtime. Amongst the novelties may be mentioned a machine for boring dynamo frames, which is being constructed by Messrs. Cunliffe & Croom. Brassfounders and coppersmiths are well employed and have a full supply of orders. There is a good deal of activity in textile machines, India and Japan taking a fair quantity of spinning and weaving machines. There is a rather better tone in the cotton trade owing to the more satisfactory results of the past quarter, and orders for replacements are coming to hand. Most machinists are unable to give quick delivery, and are finding this more difficult weekly, owing to the press of orders. Loom makers keep fairly employed, but there is not the pressure in this department which exists in the spinning machine trade.

Miners' Wages.—The annual report of one of the local miners' associations deals with the question of the advance of wages, and shows that, while these are nearly 30 per cent., the price of coal has increased 35 to 45 per cent. It was stated that the membership of this association, which includes the districts of Haydock, Little Lever, and Burnley, had increased from 4,500 to 9,000, the income being thus doubled. It is also stated that £1,800 had been expended in strikes, some of which were against the use of roburite. The prejudice against the latter is, however, dying away.

The Manchester Linen and Jute Trades.—There has not been time as yet for a real commencement of the season's trade, but orders have nevertheless been received in satisfactory volume. Jute apron cloths have been in extensive request, and an increasing trade is now passing in these goods. The consumption of flaxen and other fabrics made from that class of yarns has fallen off, owing to the popularity of cotton roughs. The latter, however, are now falling off, and a return to the linen article is looked forward to. Linen goods are purchasable to-day at as low a level as they are likely to reach for some time to come. Damask table-covers for table-cloths are used much more extensively than formerly, and this has encouraged designers to put forth greater efforts. A leaning has been noticed of late towards floral as opposed to geometrical patterns, which for a considerable period have occupied the front position in the estimation of buyers. Irish bleachers are said to have been devoting their energies to the pushing of their trade with Scotch manufacturers, and have offered to do work at prices which many Scotch bleachers say they cannot touch. Agents here are pointing out to buyers that with the rise in fuel (amounting in the case of some firms in Fife to 55 per cent.) it is impossible to continue at the rates which have hitherto been current. This action helps to make the tone of the market a good deal firmer than would otherwise be the case.

GLASGOW, 9th January, 1890.

Pig Iron.—Some uncertainty prevails in the iron ring, regarding the near prospects of trade. A few dealers express the opinion that at the present rate of production, and with smaller shipments from here and from Middlesbrough, the present high prices cannot be maintained without injuring business. Others again say that the trade for months to come will continue to absorb all the available production, and to make heavy inroads into the stocks. So far as this year has gone, the deliveries out of store have been on a large scale. Speculation has gone chiefly upon hematite warrants, which are now about 17s. above Scotch. The opening price of warrants was 64s. 6d. to 65s., and at to-day's close was 65s. 6d. cash. The commencement of pig iron business on the London Metal Exchange threatens to make an important alteration in the warrant trade. The change is being stoutly resisted by the Pig Iron Association in the interests of the Scotch brokers. It is hard to say whether the traditional localisation of the iron market in Glasgow will suffice to prevent the innovation having any serious effects.

General.—The holidays at most of the shipyards and engineering works lasted until Tuesday of this week, when the works were opened.

Clyde Trust.—Owing to the retirement and subsequent death of the general manager, Mr. George Keith, the Trust advertised for a successor. There were sixty-seven applicants for the post; but it has been decided not to appoint anyone in the meantime to occupy the position of general manager, but to consider the advisability of appointing a secretary simply. In this case fresh advertisement will necessarily be made. The trustees will this session promote in Parliament a Bill authorising them to effect an important alteration in the plan of the new Cessnock Dock. The opposition of the Commissioners of Govan to the proposal to cross the entrance to the dock by means of a swing bridge has led the engineer of the Trust to carry a road round the dock in such a way as to avoid the necessity of constructing a swing bridge. The traffic would by these means be enabled to go on without interruption.

Proposed Public Safe Deposit.—A company lately established in London, by Mr. Charles W. Milne, formerly of Glasgow, purposes establishing a public strong room in Glasgow. The arrangements will be similar to those of the well-known strong room in Chancery-lane. The chairman of the Security Company is Mr. Howard Vincent, and Sir G. H. Chubb is deputy-chairman. Mr. Milne is managing director. Fidelity guarantee is also a branch of the business of the company. The capital is to be £125,000 in shares of £5 each. Public strong rooms are to be provided in London and in Birmingham, as well as in Glasgow.

Shipbuilding.—New orders are being booked at advanced prices. A good deal of tonnage is changing hands in the market. £5 to £7 per ton dead-weight is the ruling rate.

(From our own Correspondents.)

LIVERPOOL, 8th January, 1890.

The Timber Trade.—The import season has now practically closed, leaving the stocks far heavier than desirable, and within the past month prices have with difficulty been maintained, and in some cases have declined. In furniture woods there has been an active demand for all descriptions of mahogany; stocks are light, and prices firm. The stock of Honduras, Tabasco, and Minatitlan wood is exhausted, and one cargo of Tecolutla has been imported and will be brought to auction early this month. The import of St. Domingo has been limited; curls are in active demand and command good prices. Cuba mahogany is in request, and the market is bare. There is little demand for either Honduras or Mexican cedar, and at reduced prices; there is, however, a good stock. South American finds no sale even at low prices. The stock of American walnut is ample, and Italian and Circassian is seldom asked for. There has been a fair demand for whitewood at improved prices. The market is bare of satinwood, and new supplies would command good prices. Prime lignum vitæ is in great request, and realises very high prices. Lancewood spars are also in good demand, and prices rule high on account of the limited supplies.

Increase of Cartage Rates.—In consequence of the representation made to the different merchants by the master carters, in many cases advances have been granted. The higher rates have not been asked for in anticipation of a carters' strike, for, although there is a question as to whether the men are entitled to overtime when working in the stable, the relations between masters and men are amicable and satisfactory. The carters work 13 hours a day with their horses in gear, and receive 6d. per hour for overtime.

The Live Stock and Fresh Meat Trade.—The imports for the last year are much in excess of those for the previous year, the total amounts being: 166,227 cattle, 34,369 sheep, 685,318 quarters of beef, and 613 carcases of mutton, showing an increase of 76,073 cattle, 5,995 sheep, and 274,965 quarters of beef. The arrivals during the past week amount to 3,210 cattle, 17,407 quarters of beef, and 75 carcases of mutton.

SHEFFIELD, 8th January, 1890.

Coal and Coke.—Business has now been resumed after the holidays; the collieries and coke ovens are in full operation. There is a very good demand for fuel of all kinds; in fact, the demand is in excess of the supply. The advance in miners' wages has naturally caused an increase in the price of fuel, which is now quoted as follows: Best

Digitized by Google

engine slack, 9s. to 11s; house coal, according to quality, 14s. to 17s.; best Barnsley coal, 13s. Smudge is now making from 3s. to 5s. 6d. per ton; coke for steel melting, 23s. to 27s. per ton; other qualities at proportionate rates.

IRON AND STEEL.—Makers commence the year with their books well filled with orders, and do not care to book any more owing to the prospect of further advances in value. Common forge iron, Derbyshire and Lincolnshire, is quoted at 70s. to 72s.; hoops, £8 to £9; hematites, 88s. to 90s; marked bars, £9 to £10; Staffordshire bars, £11; hematite pig, £5 per ton. All grades of steel have advanced in prices with the new year, and have still an upward tendency. Bessemer steel is quoted at from £8 to £9. The Bessemer steel works have orders now on their books to last far into the year.

ENGINEERING.—Now that the usual annual repairs and alterations are finished, engineers are again turning their attention to new work, of which there is at present plenty, although it is almost entirely of local requirement. Special machines for labour saving are now being largely adopted. Punching and shearing machines and small steam hammers are in much request.

NORTH STAFFORDSHIRE, 8TH JANUARY, 1890.

THE IRON TRADE.—Operations have been generally resumed after the Christmas and New Year holidays. Makers find a good demand for new work and specifications on old contracts are coming in freely. The quarterly meeting of the local Coal and Ironmasters' Association was held at Stoke-on-Trent on Monday, but business was generally deferred till the meeting at Birmingham on Thursday. The demand for pig iron continues to exceed the capacity of supply, and prices are moving upwards rapidly.

THE POTTERY TRADE.—As the result of many meetings held during the last few months, manufacturers have now come to an arrangement to put up the price of China goods 12½ per cent. There is little doubt that a similar advance will shortly be declared on earthenware. Nevertheless, it is a fact that considerable competition for orders prevails, and unless a healthier demand springs up buyers will still be able to buy goods at pretty much their own values.

LEICESTER, 8TH JANUARY, 1890.

WOOL SPINNING AND YARN TRADES.—The year has opened cheerfully, with a buoyant tone generally pervading the wool market. The tendency downward of prices has disappeared, and staplers are holding their stocks firmly and do not press sales. The late highest rates are fully maintained, and the prospect points to a probability of a further small advance. Spinners are generally running their stocks down and hesitate to come into the market, but with the continuance of the present heavy consumption they will soon have to make large purchases. Spinners recommenced business with a good supply of orders on hand and the mills are mostly fully employed. They are chary of accepting new business at late rates, and some considerable contracts have been declined. Yarn merchants are becoming busier, and though cashmeres were 3d. to 6d. per lb. dearer at the close of last year than the beginning, they are not eager to book at the late rates.

HOSIERY TRADE.—Business has not yet got into working order after the holidays, but there is a fair amount doing, and the prospect of the spring trade is cheerful. Some large buyers are now in the market, and orders are being booked freely. As stocks are low the trade will soon revive under the new commissions.

BOOT AND SHOE TRADE.—Most of the houses are now in full work and with some good orders on hand. The business of the year has opened well, and a very cheerful feeling pervades the trade. It appears certain that a very good trade will be done in the next few months. Leather merchants are doing a good business with new contracts. There is a tendency to harden the price of some descriptions.

SWANSEA, 8TH JANUARY, 1890.

TINPLATES.—The continued increase in the cost of raw materials, and the difficulty of obtaining steel bars, render it almost certain that much higher prices will rule after next Thursday's quarterly meeting of the trade at Birmingham. Quotations, which still remain on the basis of 16s. 6d. for Bessemer cokes, are purely nominal. The Raglan Bay Tinplate Company, registered with a capital of £25,000, intend commencing operations with three mills, and have taken four acres of land at Briton Ferry, upon which they are about to erect works. The warehouse accommodation in Swansea has recently been tried to its utmost, and will soon prove inadequate for the growing requirements of the trade. We may therefore look for extensions in the immediate future.

THE LABOUR MARKET.—The coal miners have as yet been unable to come to any agreement with the masters on the subject of the standard upon which to found the new sliding scale, and the 7,000 workmen employed at the Ocean Collieries demand a 10 per cent. advance. The Cape Copper Company's smelters at Neath have also organised an agitation for an increase of wages, and take pride in being the first body of men engaged in this industry who have adopted the principle of trades unionism. A strike occurred at the Briton Ferry Chemical Works owing to a section of the men seeking an increase of wages. The difficulties encountered by the Mannesmann Tube Company arose from a different cause. Friction at these works was created by the introduction of a number of German workmen, ostensibly to start the manufacture and instruct the Welsh hands, who, however, have looked upon the movement as one calculated to take the bread out of their mouths. Pleasanter is it to record that from the beginning of the new year the directors of the Alexandra Docks, Newport, have raised the wages of traffic men 10 per cent., and have so arranged work that there are three shifts of eight hours each. The men engaged in the engineering trades at Newport are fully employed, the Uskside Engineering Company especially being very full of orders for mining plant of every kind.

BARRY DOCK AND RAILWAY.—Although only opened for traffic on the 18th of last July, 1,088,457 tons of coal and coke had been exported by the end of 1889. This, together with 14,745 tons of imports will suffice, notwithstanding the recent war of rates, to pay the interest on the debentures and on the preference stocks of the company, leaving besides something for the ordinary shareholders, which it is estimated will not be much short of 3 per cent. per annum on their holding.

BARROW-IN-FURNESS, 8TH JANUARY, 1890.

IRON AND STEEL.—There is again a very marked upward tendency in the hematite pig iron trade, and it comes all the more significantly after the few weeks of a lull towards the close of the year. Mixed parcels of Bessemer iron are quoted at 82s. 6d. per ton net f.o.b., and No. 3 forge and foundry iron is quoted at 81s. 6d. per ton, the highest prices touched for many years. There is a large delivery of pig iron, and this is likely to be fully maintained both by rail and by sea. The stocks of iron held in warrants have fallen during the week by 500 tons, but they still stand at 380,847 tons, while the pig iron held by makers will bring this figure up to about 450,000 tons. The pig iron shipments during the week were 12,877 tons, and the shipments of steel 7,214 tons. In the steel trade there has also been an improvement, not so much in the demand as in prices. Rails, which are in full inquiry, especially from the Colonies, have advanced in price to £7 5s. per ton for ordinary sections and £8 5s. to £8 10s. per ton for colliery sections. Ship plates and angles are in full demand, the former at £8 15s., and the latter at £7 15s. per ton. Spiegeleisen has gone up in price to an alarming extent, being now quoted at £6 10s. per ton for 20 per cent qualities.

SHIPBUILDING AND ENGINEERING.—The prospects in these trades are very bright, and as the price of material has advanced to so marked an extent it is not surprising to find that owners of steamships are directing their attention to the re-engining of their old vessels with triple expansion engines in preference to the building of new ships at the present necessarily heavy cost. It is probable that much of this class of work will come to Barrow during the present year.

THE TIMBER TRADE.—Very large supplies of timber have come to hand during the past few months, and stocks are therefore higher than they have been for many years past. There is, however, a large demand for all classes of building, shipbuilding, and mining timber, and good prices are ruling.

MIDDLESBROUGH, 8TH JANUARY, 1890.

PIG IRON.—The market is strong, and prices are advancing. No. 3 G.M.B. cannot be got under 64s. 6d., and some merchants and makers are holding out for 65s., prompt delivery. There is a greater inquiry for forward delivery, for which 66s. is quoted. Warrants are eagerly bought up by a few strong holders, who have every confidence that, as the season advances, the prices will rise. Cleveland warrants are quoted at 65s. 4d., and makers' hematite mixed numbers at 80s. Connal's store is increasing. On Monday, the 6th inst., the amount of stocks was 183,248 tons.

EXPORTS OF PIG IRON.—The exports of pig iron have fallen away very much, chiefly owing to the season of the year, and not to the want of demand. For the current month, up to the 6th, they amounted to 8,595 tons, against 10,685 tons to a similar date last year. The exports for the past year have been very good, having amounted, as a whole, to 959,520 tons, 409,783 of which went coastwise and 549,737 abroad. Scotland, Germany, and Holland have been the best customers.

DECEMBER STATISTICS OF THE CLEVELAND IRON TRADE.—There was a total make of Cleveland iron amounting to 134,760 tons. These were disposed of thus:—38,080 tons were shipped from Middlesbrough, and 74,183 tons were consumed locally or sent off by rail. The total stocks, which at the end of November stood at 239,888 tons, at the end of December amounted to 262,385 tons, having increased by 22,497 tons. The average market price of No. 3 G.M.B. for the month was 62s. as against 64s. for November.

SUNDERLAND, 8TH JANUARY, 1890.

MARINE ENGINEERING.—Although there are five marine engineering establishments at this port as compared with four in 1888, the local output of engines and boilers has not kept pace with the increased number of vessels launched, only about 68 out of the 99 steamers built being engined in the port. Several vessels have obtained their engines from West Hartlepool, and other places even as far away as Glasgow. Mr. John Dickinson, Palmer's Hill Engine Works, has the best return—viz, twenty-two new steamers fitted with triple expansion engines and boilers, and one vessel with "converted engines," besides supplying over one hundred of his patent crankshafts. Mr. George Clark, Southwick Engine Works, and the North Eastern Marine Engineering Company, South Dock, have each turned out 16 or 17 sets of triple expansion engines, and Messrs. Doxford & Son similarly fitted eight of the vessels built in their shipbuilding yard, besides carrying out a number of alterations. At the Scotia Engine Works Messrs. Wm. Allan & Co. have quadrupled four vessels' compound engines, and constructed besides two new sets of quadruple expansions, one set of "triples," and re-boilered the steamer "Eagle." So far as we can ascertain, there has not thus been much actual increase in the work executed on this river in this department, the North-Eastern Marine Engineering Company and Mr. George Clark having had decreased outputs. As Messrs. Wm. Allan & Co. completed their first engine about the middle of the year, their returns are not unsatisfactory. The prospects for the coming year appear to be good in each of the establishments.

NEWCASTLE, 8TH JANUARY, 1890.

SHIPBUILDING.—Although many employers were desirous that the stoppage for the New Year holidays should terminate on the 2nd inst., they very generally found themselves unable to give effect to the wish, and it was not till the beginning of this week that the whole of the yards were again opened for work and the normal state of things was restored. Now, however, there will be some pressure put on for a few weeks, as all concerned will be interested in making up for lost time. The year opens with excellent prospects for the industry, as, in spite of the fact that orders enough have been placed to keep the yards busy over the whole of the twelvemonths, more contracts could now be obtained if builders cared to accept them. The only possibility that seems likely to hinder the smooth run of business prosperity this year is the occurrence of wages disputes, and in view of the unfortunate results which usually accrue from these contests, it would be well if the parties interested would begin the year by taking steps for the establishment of a Board of Arbitration and Conciliation for the amicable settlement of such matters. Such a board has been in existence on the Wear for some years, and has been found effectual for the purpose indicated.

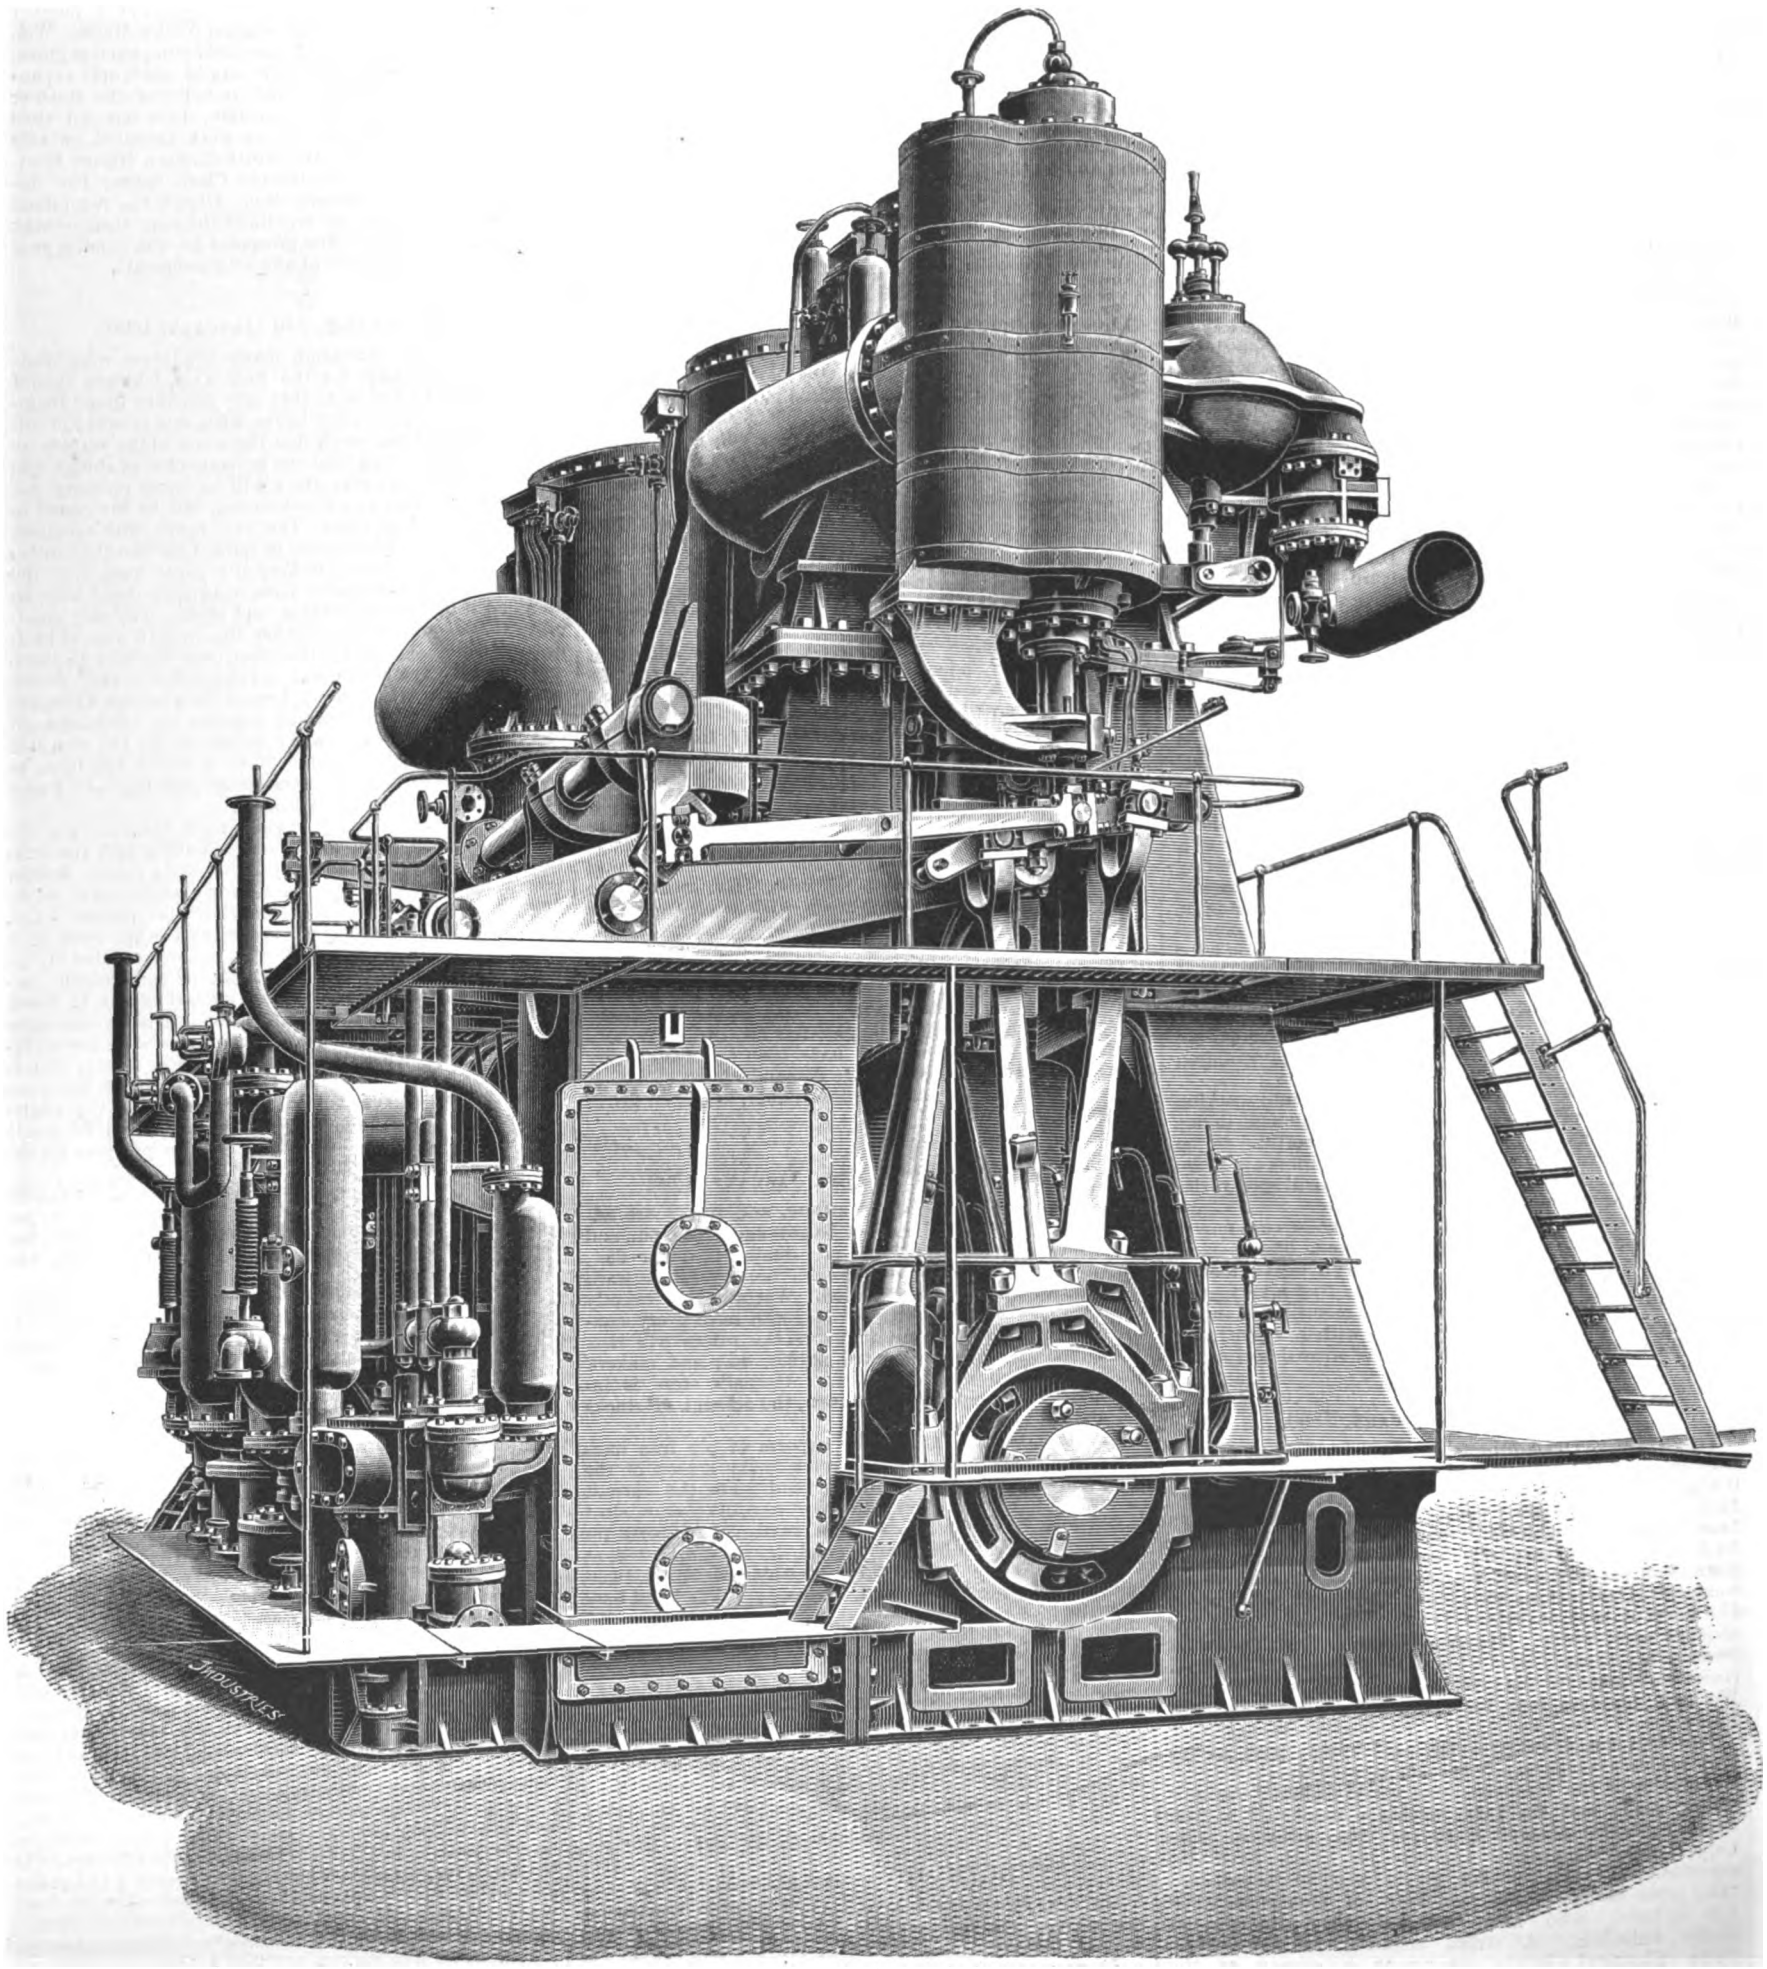
ENGINEERING.—In the engineering establishments the year commences well, work being plentiful and the relations of employers and employed unusually good. Among the engineering firms that have shown exceptional briskness during last year is Messrs. Hawthorn, Leslie, & Co., who have had Government orders and other work of a special class to deal with, and who, in the execution of the more important contracts, have achieved conspicuous success. This firm have now several special orders in hand, and the operations of the year will doubtless be even more important than those of last. For a firm who do not exclusively devote themselves to marine work, Messrs. Black, Hawthorn, & Co. accomplished a remarkable feat last year, supplying fifteen vessels with their machinery, the aggregate indicated horse-power of which amounted to nearly 15,000. In the case of this firm, also, the prospect for the present year is excellent.

WAGES MOVEMENTS.—The stonemasons of Newcastle have given notice for an advance equivalent to 2s. per week in the wages rate. An advance of 15 per cent. has been asked for on behalf of the labourers in shipyards and engine works.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock for the week ending January 4th amounted to 75,924 tons, being a decrease of 10,670 tons as compared with the shipments for the corresponding week last year.

BELFAST, 8TH JANUARY, 1890.

LINEN TRADE.—On the 3rd inst. the reelers in the employment of the Bessbrook Spinning and Weaving Company refused to resume work unless they were granted a rise of wages. This has been refused, and, the strikers not returning, the entire works have been closed, and over 4,000 hands thrown idle. Owing to the holidays the business done during the past fortnight has been rather small, but, on the whole, there is a very good tone over all, and a considerable improvement is now confidently looked for. The number of looms is increasing.



SHIPBUILDING AND ENGINEERING.—Since the holidays very little work has been done, especially in the shipyards, owing to the bad weather. It was not until the beginning of the present week that anything like a fair start was made. Work continues plentiful. All the stocks are full, and there are several steamers of large tonnage in the water being finished. Irish shipbuilders have every reason to be satisfied with their turn out of tonnage during the past year, and are looking forward to another equally good one. Messrs. McIlwaine & McColl, Limited, sustained a severe loss by fire on the 3rd inst., when the drawing office and pattern shop of their engine works were destroyed. The fire is supposed to have originated in the adjoining copper works of Messrs. Cleland & Thorburn, which were entirely destroyed. Machine and tool makers are very actively employed, and in some cases large foreign orders are in hand.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, Bedford Street, Strand, London, W.C.*

FRIDAY, 10TH JANUARY, 1890.

STEAM BOILER LEGISLATION.

THE inquiry into the unfortunate Charlesworth boiler explosion case, which was held on the 18th ult., has raised anew the question of boiler legislation. Briefly, the evidence went to show that a second-hand boiler was purchased by Messrs. George Booth & Sons in 1874; that this boiler was supposed to be about a year old, had cost £41, and was worked for several years, for heating purposes simply, at a pressure of 20lb. per square inch. In 1884, however, additional work was required from the boiler, and the working pressure was raised from 20lb. to 40lb. In 1882 and in 1887 some repairs were executed, but in the fifteen years during which the boiler was in the possession of the owners they admitted it was never once "thoroughly examined or tested." One of the partners, who had charge of the boiler, and who lost his life by the explosion, "had had no experience of steam boilers, though he had some idea of stoking and keeping up steam. It would not have paid to have employed a regular attendant." In May, 1889, the boiler was insured with the Engine Boiler and Employers' Liability Insurance Company for £300, at an annual premium of £1 10s. After a preliminary inspection while the boiler was working, a policy was issued, and in August a further examination was made by the inspector of the company. The report, which was submitted to the owners two days after the inspection, showed that the plates below the water-line were pitted by corrosion to the depth of an eighth of an inch, and the company in consequence of the defective plates recommended that the boiler, being of great age, should be subjected to a "thorough examination." This report was not acted upon. The owners resolved to wait till Christmas, and the boiler exploded on November 1st, killing Mr. R. Booth and his manager. The examination of witnesses at the inquiry turned chiefly upon the following points:—Whether or not the owners took measures, between the date of the purchase of boiler in 1874 and the date of insurance in 1889, to satisfy themselves that the boiler was in a safe condition; whether the boiler was at any time under competent management; why the boiler was insured; and the circumstances under which the owner neglected to give effect to the recommendations of the insurance company. It was pointed out in the course of the evidence that the usual clause in boiler insurance policies—viz., the clause which intimates that the insured are under no obligation to adopt any suggestions in the insurance company's report—was present in the policy issued in this case, and also in the report of the company upon this boiler. The finding of the Commissioners was in effect that the owners were to blame in that for fifteen years no "thorough examination" was made of the boiler. As regards the position of the insurance company, the Commissioners did not find blame attachable to them, but thought that companies ought not to insure boilers unless they were convinced of their safety. They directed that the surviving owner should pay £75 towards the cost of the inquiry, and refused the application of the counsel for the Board of Trade that costs should lie against the insurance company. The Commissioners, while appropriately regretting the circumstance that the chief owner had lost his life by the explosion, stated in set terms that they considered the case "the most disgraceful that had come under their notice." This case, along with another which involved an explosion at Northwich, on October 19th, through a "gagged" safety valve, has been made the occasion of an article in the columns of a contemporary, which renews the clamour for compulsory boiler inspection. It appears to us that on any calm view neither of these cases affords any justification for drastic legislation at present. One was due to the culpable recklessness of the attendant, and the other to the procrastination of the owner. It must be remembered, in the first instance, that the Board of Trade has been singularly inert in the matter of boiler investigations. The law as it stands gives the Board very ample powers of punishing, as it has done in both the cases referred to, culpable recklessness in the management of boilers. Yet only three "formal investigations" have been held under the Act of 1882. The careless boiler owner has therefore had every encouragement to slumber in fancied security. Those who object to further legislation most strenuously assert that the law as it stands should be carried out, and that carelessness should be punished severely in the public interest. If the provisions of the Act of 1882 were consistently carried out, and an investigation ordered in all explosions where culpable carelessness was *prima facie* in evidence, the result of it would be, not only that inspection would be universal, but, what is quite as important, efficient management of boilers would become universal also. If owners are so easily lulled into security as to be satisfied that the magic process of insuring can make a twenty-year-old boiler as good as a new one, how would they regard a Board of Trade certificate otherwise than as a virtual indulgence to do what they pleased with their boilers? Thus, the effect of compulsory inspection by the Board of Trade would be hopelessly to demoralise boiler owners. Some capital has been made out of the statement, extracted from Mr. Michael Longridge in cross-examination, that "the issuing of a policy was no guarantee for its safe condition. It simply meant that the insurance company took it as a good risk." So long as human nature and other conditions affecting boilers and their use are variable, no other statement could very well be made. Would anyone assert for a moment that a Board of Trade certificate, by an inspector never so competent, would be a guarantee that the boiler "was in a safe condition"? Would a Board of Trade certificate have prevented the engineman from "gagging" the safety valve, as in the "Development" case, or Mr. Booth from imprudently raising the pressure on his boiler from 20lb. to 40lb.? The fact that in the Charlesworth case the owner paid the penalty of his blunder with his life will surely be taken as a warning by those who undertake the charge of managing boilers with no better qualification than that they had "some idea of stoking and of keeping up steam." Within certain limits the risks in boiler insurance can be reduced by the adoption of precautions, but there remains, and would inevitably remain under the most drastic legislation conceivable, an element of uncertainty such as that which exists in the case of fire and of life insurance. The Board of Trade guarantee, by whomsoever it might be granted, would be worth nothing more than the guarantee of an insurance company, and might besides limit the responsibility of the boiler owner to mere conformance with the minimum requirements of the Board of Trade. At present, as we have pointed out, the owner is responsible before the law for the condition and for the management of his boiler; he cannot, as has been shown distinctly

Digitized by Google

in the finding of the Commissioners in the Charlesworth case, shift the responsibility from his own shoulders to that of the insurance company; and our contention is, that he ought not to be allowed to shift it on to the shoulders of any one. One important amendment ought, however, to be made in the Bill of 1882—that is, to make the registration of boilers compulsory, so that it may be known to all concerned where boilers are working. Further than this we do not conceive it would be wise to go on adding to the already considerable powers given by boiler legislation. The Commissioners which the Board of Trade may appoint under the 1882 Act have all the powers of a court of summary jurisdiction, and the exercise of these powers, when the court is set in motion in any particular case, would do more to show the need of scrupulous care in the management of boilers than would any apparently direct, but really roundabout, and inevitably arbitrary, legislation. The often-repeated but altogether unwarranted assertion, that it pays the insurance companies better to run the risk of explosions than to give thorough inspection, has been recently stated, but it bears its refutation on its face. An explosion which could be proved to be due to dereliction of duty on the part of an insurance company would most seriously affect that company's position. In the Charlesworth case, for example, had the company not shown that they had reported adversely upon the condition of the boiler, there is no doubt that they would, and justly, have been mulcted in costs and would have suffered in prestige. It cannot be too strenuously insisted upon that the use of the boiler is as absolutely important an element as its construction and foundation. In the hands of one man a boiler may remain in good condition for years, while in the hands of another, or in certain situations, it may be corroded to a dangerous extent in a few months. This makes it all the more necessary that the onus of the safety of the boiler should rest upon the owner and upon no one else, and also that safety should not be defined to be a certain thickness of plate in construction, or in the compulsory use of certain special boiler fittings in preference to others, but that the owner should be compelled to secure, so far as is humanly possible, that his boiler shall be soundly constructed for his requirements, whatever they may be, and also carefully used.

Among the results which would naturally follow from the arbitrary dictation by the Board of Trade of a certain thickness of plate and certain fittings, would be inevitaby the stultification of invention. All the exasperating incidents of obtaining approval of inventions by the Board of Trade would be extended into a new sphere. Our public departments already sit, like the "Old Man of the Sea," upon many branches of industry. It is well to resist further encroachments of this kind. The Electric Lighting Act, passed in a burst of enthusiasm for State control of industry, has retarded the progress of electric lighting quite sufficiently obviously to convince the most sceptical. To saddle boiler insurance with similar legislative disabilities would be a parallel mistake, which steam users would deplore. No one desires more than we do, that the loss of life from boiler explosions should be mimimised; but we contend that the imposition of a few sharp punishments, such as were meted out in the "Charlesworth" and "Development" cases, would do more to make careless boiler owners careful, than legislation, which would hamper everybody, with only a slender likelihood of doing anything else. In face of some disposition to promote legislation for compulsory inspection on the part of a section of the public, who have not the opportunity of seeing all round the matter, the companies would certainly do well to adopt the recommendations of the Commissioners in the "Charlesworth" case, and refuse to insure boilers which they did not consider safe. The existence of the 1882 Act really meets all practical requirements. It goes without saying, that while the law may be used as an engine for compelling the recalcitrant, it ought not to be used to impede the development of industry, or to relieve people from the responsibilities they voluntarily undertake.

Much of our legislation is manœuvred into existence by sheer fuss; and no branch has suffered more from this than industrial legislation. Pseudo-philanthropy imposes both upon Parliament and upon the public with so marvellous facility, that it is necessary to counteract this influence by the infusion of some steady common sense into industrial politics. What people want is not a mechanism which will compel them to do right; but a principle which will prevent them from doing wrong. This must be definitely taken account of by projectors of boiler bills. Their method of achieving a result, unquestionably desirable in itself, is after all a happy-go-lucky method. Whether or not the Board of Trade intend to act through insurance companies, compulsory inspection would involve an addition to our already considerable bureaucracy.

THE SPEED OF VESSELS IN OUR NAVY.

In recent years naval officers have made themselves heard as regards the constructive details of our war ships viewed as fighting machines, and in none have they been more emphatic than in that relating to speed. The purport of their argument has been that, if a vessel has not a preponderating influence in armour and guns to enable her to give battle with some chance of success, she should certainly be provided with a high speed to show a clean pair of heels if desirable. It was no easy task to move aside the antiquated notions of the Admiralty in this respect. Other Powers were, however, so pronounceably ahead of us on this question, that example and argument at length prevailed. Fast cruisers of 18 knots and higher speeds were built, and have met with all the success that was to be expected from them. Why this important factor of naval construction was neglected for so long was, and is still, a mystery to outsiders. Yet, when put to the test, we out-distance our competitors, and probably possess to-day the fastest ships of any navy. Premising, then, that speed is the first element of safety that an unarmoured man-of-war can possess in a critical moment, and ranks before roominess, sail-carrying power, or handiness, of which we used to hear so much in the past, how comes it that several small vessels have been built lately to crawl along at a top rate of 12 knots on a trial trip? True, these vessels are small—800 to 1,000 tons only; but they would seem to have been designed for peace purposes, fishery duties, river work, and for being kept on show instead of use were war to break out. Do the responsible authorities think enough has been done for the national honour, with all the confidence reposed in them, when attention is paid only to the leviathans in the service, and are the small craft beneath their notice? The great success that torpedo boats have had proves that moderate-sized vessels may be made to travel at a pace unknown to us twenty years ago. There is, therefore, no doubt that vessels of, say 180ft. long, can be driven at much higher speeds than that quoted—in fact, there are examples to prove this in foreign navies. How comes this apparent retrograde step, then, at a time when the country has been so lavish in its expenditure on its fighting fleet? We are very much afraid the answer is the old one for which public departments are noted in every country—viz., red-tape. This word may be said to embrace everything that may be included with love of tradition, circumlocution, and general desire how not to achieve results. Perhaps the British Government excels all others in the capacity of requiring to be goaded before it can make perceptible progress.

Let us consider for a moment what low speed in an unarmoured man of war really signifies. Take, as an extreme case, an ordinary cargo boat, with no protection and no propelling power. In the presence of an enemy's cruiser she would be inevitably captured at once. It would seem to the uninitiated mind that a ship without armour is very much in the same category as the merchantman, and to be of any value as a guard she ought to have the power for a surplus speed and the latest ordnance. It will be seen that this rule applies more to the cruiser type than to line-of-battle ships. In the former case we have a class that would be employed in time of necessity as patrols and convoys, and thus our merchant navy would be relying on a myth were the question of speed left out of consideration. That swiftness in a scout is a *sine qua non* goes without saying. What, then, with no want of funds at our disposal, can be the object of putting our officers and men at a disadvantage if they should be called upon to do their duty to the country? It is difficult to find any answer except the one we have given. To attack or defend at will, to keep the sea for a length of time, to overcome bad weather, and be an efficient protection to commerce, means, in a few words, large engine power; but our Board of Admiralty reverse the ruling of the saying "that to be at peace we must be prepared for war," and send to sea warships prepared for peace only, as far as speed is concerned. Officialdom reigns supreme, and the public is hoodwinked. Even a tyro at marine design will know that, as we have torpedo boats of 120ft. long steaming at over 20 knots, vessels of a substantial build may be propelled at more than 11 to 12 knots with ordinary draught. If the type taken be that which has obtained in the service in the past, the result is inevitable, but, with the experience that has come to us during recent years, most of the shipbuilding firms of the country would readily make themselves answerable, on a displacement of 1,000 tons, for a speed of 16 or 18 knots. The remark that such a vessel would be all engines and ordnance is beside the mark, for a vessel of this kind is a weapon of offence and defence, and it is absurd, if nothing else, to furnish a warship worthy of the name with anything short in either of these necessary vital elements. It may be said that our constructors do not have the direction of the leading features of a design in their hands. If this be the case, why does not a protest go forth against unnecessary interference? The public look to be well served, and will, if a catastrophe occur, not be slow to fix the responsibility on the shoulders of individuals. It can be easily understood that a catastrophe is within the bounds of probability if, in the present state of marine engineering, a man-of-war can only take her place in the line of battle having a speed of 12 knots as developed on a trial trip.

THE RAILWAY RATES INQUIRY.

Between the 15th of October, the date on which the inquiry before the Board of Trade commenced, and the 18th December, when an adjournment was made for the Christmas holidays, nineteen sittings were held. Verbatim minutes of the proceedings have been regularly issued to those desiring them, at a cost of 3s. per day, but it is more than probable that very few, other than those exceptionally engrossed in the inquiry, have waded through this mass of literary work. And, indeed, but little profit could result from such a course. The question presents itself, then, as to how far the inquiry has tended towards an agreement between the railway companies and the traders on the questions at issue, for that is the primary object of the arbitration. And the answer is not of a reassuring character. The main points in dispute relate to the maximum and actual charges to be made by the railway companies, these being dependent on the classifications, and the incidence of terminals. The railway companies appear to claim that there is no reason why the existing maximum powers should be reduced, as the actual rates charged are made dependent partly on the requirements of the districts concerned and partly on the cost of conveyance and working. The traders maintain that actual working rates should be arranged, and the classifications should be so scheduled as to afford substantial relief to the industries of the country. With regard to terminals the companies hold that the charges allowed should be determined by the amount of accommodation afforded and the cost of the construction and maintenance of station properties. Some of the traders protest against the imposition of terminal charges under any circumstances whatever, contending that the costs of station and siding accommodation are expenses incidental to the "conveyance of goods," and not to the duties of a "carrier." Others, from the force of circumstances, admitting the claim, have joined issue as to the assessable value of the services in question. These appear, briefly stated, to be the two main points round which the battle is being waged, but they open out innumerable avenues of minor issues of a complicated character. So far, three or four of the general managers of the largest railway companies have been examined, cross-examined, and re-examined, and this is all the progress which has been made. It has been decided to appoint an expert to check the figures produced by the railway companies as to the cost of sixteen of what are alleged to be fairly typical stations, in connection with the question of terminals; but no matter in which a principle is involved is to be referred to him. The traders have been hard pressed to declare their objections in detail and to submit alternative constructive propositions.

The enormous cost of the arbitrament to the railway companies and to the traders must strike the most casual observer who has attended any of the sittings, and it appears to those who have the question at heart, and have watched the proceedings, that there is but the faintest prospect of any benefit being derived therefrom. The inquiry is yet in an initial stage, progress is slow, and a vista of almost interminable longevity presents itself. Whether the Railway and Canal Traffic Act, 1888, is likely to prove of any commercial benefit to trade during the present century seems questionable indeed.

DIFFICULTIES OF FOREIGN ENTERPRISE IN CHINA.

As illustrating the difficulties which foreign enterprise may for some time be expected to encounter in China, we may instance the scheme for the navigation of the Upper Yangtse to the port of Chung King, with which the name of Mr. Archibald Little has been associated. By the Cheefoo Convention of 1877 this port was to be opened to foreign trade whenever a steamer ascended the rapids to it. Taking advantage of this clause, in 1885 Mr. Little applied for a permit to do this, but the Chinese Government told him to first get his steamer and then he would get the permit. Mr. Little accordingly got up a small company, and built a steamer, which was sent out to China in 1887. When, however, he applied for the permit, he was bandied about from the Imperial to the local authorities, and without any satisfactory result, until at last the company's funds were exhausted, for all this time the crew was being maintained at considerable expense. When the Chinese thought they had sufficiently exhausted the resources of the company, they made an offer to purchase the steamer, provided Mr. Little and his company should abandon all attempts to ascend the river and all demands for a permit for ten years. This offer was declined, and Mr. Little returned to London during last summer to try to induce the Foreign Office to put pressure on the Chinese Government to grant a permit, and also to claim compensation for loss caused by the delay. Recently negotiations were reopened in London by the representatives of the Chinese Government, and an agreement was come to whereby Mr. Little's steamer was purchased and a liberal allowance made for all expenses incurred, and no stipulation made as to the future. The treaty rights of British subjects thus remain the same as before, and, no doubt, encouraged by the example of Mr. Little, another attempt will be made to supply ships for a department of navigation which, when developed, will be of great importance. In the meantime the Chinese have got a steamer which has been specially designed for ascending the rapids, but which is of little use for ordinary navigation, and they must either make the attempt themselves or be content to allow their money to be practically lost. The whole affair may be useful to foreigners, as showing them the disappointments which they, for some time at least, may expect when they attempt to take the initiative in any work in China.

PROPOSED GLASGOW AND DISTRICT SUBWAY.

The promoters of the proposed subway in Glasgow and district have not been discouraged by their want of success on their first attempt, and, with the guidance of their engineers, Messrs. Simpson & Wilson, have brought out an improved scheme, for which they propose to ask powers in the next session of Parliament to construct. The route commences in St. Enoch Square, and includes in its circuit the north and west parts of the city, as well as the most populous parts on the south side of the river, which necessitates it passing twice underneath the river. There are to be two tunnels, each 12ft. diameter, along the whole course of the line, to be formed of cast iron segments 1in. thick. They will be 35ft. under low water level, or 55ft. below quay level. The total length of the line will be 6¼ miles, and on the route fifteen or sixteen stations are to be constructed. At the stations the two tunnels will be joined by an arch rising 11ft. above the platform, which will be formed between the two lines, and in each case will measure 10ft. wide and 130ft. long. The waiting-rooms, &c., are to be on the street level, stairs and hydraulic hoists being provided, but, as it is arranged that no passenger will require to wait more than two minutes for a train, there will not be much occasion to use the waiting-rooms. The trains are to be drawn by the endless wire-rope system, so that a continuous service will be provided, and all inconveniences of defective ventilation will be avoided. The method of construction to be adopted is the pneumatic process which has been recently adopted in several important engineering works, and which will allow the whole work to be executed entirely under ground, with only one or two shafts for raising the material to the street level, a method which will, of course, greatly increase the expense, but will not interfere with the traffic in the streets. The diameter of each tunnel, as already mentioned, will be 12ft., with a clear height of 10ft. above the level of the rails. The distance between the two tunnels is 6ft. The level of the top of the arch below the street varies from 21ft. to 122ft., while each station will be from 30ft. to 40ft. below the street level. The line does not interfere with any of the Clyde shipbuilding yards, and as the chief objections to the former scheme have been avoided, or at least modified, it is very probable that the present proposals will be confirmed by Parliament, and if they are carried out they will add immensely to the travelling conveniences of Glasgow, especially in connecting the west and south parts of the city, which at present are very inaccessible to each other.

THE ROYAL INSTITUTION LECTURES FOR JUVENILES.

On the 2nd inst. Professor Rücker continued his lectures on "Electricity." Further illustrations were given of phosphorescence by the discharge of electricity in rarified gases, the stream of electrified particles striking against lazaea stone, pectolite, and Iceland spar, and giving brilliant lights of various tints. By various experiments it was shown that electricity was capable of producing motion in a body and of overcoming resistance. When two electrified bodies meet, and there is an electrical discharge, what has become of the energy? It still exists, the lecturer said, in a different form. By an analogy of moving bodies coming into contact, and also by experiments, it was proved that the electrical energy was converted into heat. A piece of looking-glass struck by lightning at Durham was shown upon the screen. The silvered surface was burnt into the glass. The whole effect was probably not merely produced by heat, but partly due to mechanical action. The instantaneous nature of lightning was shown by the passage of a spark, first over a motionless glass plate coated with lamp black, and, secondly, over a similar plate revolving at least 45 times a second. The marks produced on the lamp black were very similar.

Some beautiful photographs by Dr. Hüffer (taken during the storm in June last) were exhibited. It could be seen from these photographs that what appeared to the eye as one flash was in reality composed of several.

The fourth lecture, delivered on the 4th inst., commenced with an explanation of "potential." Although (as shown in a previous lecture) electricity tended to accumulate most at the most pointed part of the conductor, the tendency of flow is the same in all parts. Reference was made to the distribution of electricity on bodies in relation to electrified bodies, and it was shown that the introduction of a conductor altered the potential of the electrified body.

The effect of electricity in decomposing chemical substances was next demonstrated. The substance chosen was acetate of lead, and on an electrical current being passed the chemical action was easily observed. Up to a certain point absence of air in a tube facilitated the flow of electricity from one terminal to another. Either exhausting the air too far or having too much air impedes the flow of the electrical current, and at last stops it. At the conclusion the lecturer exhibited the "Vacuum tubes" of Messrs. De la Rue, containing gases of varying densities—namely, hydrogen, carbonic acid, air. The striations were most pronounced, and in the tubes of irregular shapes the colour was brightest where the tube was narrowest.

The fifth lecture, on 7th inst., consisted essentially in showing the application of electricity to the service of man. Explanation was given of the principles on which the electric telegraph, electric bells, and the telephone were worked. By means of diagrams and models Edison's receiver and Blake's transmitter were explained. Some interesting figures were given with reference to the National Telephone Company. In London they have 23 exchanges, with 5,500 subscribers. As many as 28,000 connections are made daily in the metropolitan area. This is, of course, in excess of the messages, as two or three connections have often to be made for each message. By the courtesy of the Company, connection was made between the Croydon Exchange and the Theatre of the Royal Institution. By means of the loud speaking telephone the whole audience could hear what was being said ten miles off.

INDUSTRIAL WILLS OF 1889.

The following wills connected with industrial celebrities were proved in 1889. In each case the personal estate alone is given:—

Iron and Steel Manufactures.—Mr. Robt. Fowler, steam plough works, Leeds, £219,617; Mr. Richard Peacock, M.P., locomotive builder, Gorton, £204,159; Mr. Robert S. Newall, submarine cables, Gateshead, £166,981; Mr. Edwin L. Pease, Skorne Ironworks, Darlington, £142,694; Mr. P. H. Muntz, Leamington, £95,000; Mr. James Howard, agricultural implements, Bedford, £82,702; Mr. G. N. Vickers, steel manufacturer, London, £71,000.

Coal.—Mr. William Hedley, Burnhopeside, colliery owner, £174,119; Lord Dunsany, Pelton Collieries, £137,880; Mr. Jonathan Priestly, colliery owner, Shotley Bridge, £97,945; Mr. Ed. T. Boyd, mineral agent, Leamside, Durham, £42,983; Mr. Herbert Clarke, London, coal merchant, £157,336.

Railways.—Sir Daniel Gooch, Bart., chairman, Great Western Company, £693,492; Col. McMurdo, Delagoa Bay Concession, £395,780; Charles Sacré, chief engineer, Manchester, Sheffield, & Lincolnshire Railway, £165,000; Mr. Robert G. Underdown, manager, Manchester, Sheffield, & Lincolnshire Railway, £62,841; Sir James Falshaw, Bart., railway engineer, Edinburgh, £88,000.

Shipping.—Sir William Pearce, Bart. (Messrs. Elder & Co.), Govan, shipbuilders, £1,069,000; Mr. T. D. Hornby, chairman, Mersey Docks and Harbour Board, £159,319; Mr. Alex. Petrie, shipowner, Stockton, £33,000.

Chemicals.—Mr. W. J. Cookson, Worksop and Newcastle-on-Tyne, £585,000; Mr. James Cant, £216,000; Mr. F. J. Bryant (Bryant & May), £272,321.

Cotton, Linen, and Woollen Goods.—Mr. John Rylands, founder of Rylands & Son, London and Manchester, £2,574,922; Mr. Julius Behrens, Manchester, £420,000; Mrs. Margaret Platt, Staleybridge Mills, £412,000; Sir William Ewart, Bart., M.P., Belfast, linen manufacturer, £350,000; Mr. James Murray, Manchester, cotton spinner, £325,053; Mr. William Carver, ditto, £272,252; Mr. David Spencer, woollendraper, Coventry, £240,000; Mr. William Tipping, of Bold, £235,406.

Leather Trades.—Mr. R. Borras, fur manufacturer, Old Change, £82,000; Mr. John Southgate, portmanteaus, City, £80,000; Mr. James Chaloner West, leatherdresser, Bermondsey, £46,000; Mr. Ed. Wm. Clarke, boots, London, £41,000; Mr. John Oaster, Bermondsey, tanner, £20,000.

Provisions.—Mr. George Borwick, baking powder, £259,740; Mr. J. Collier Harter, Leamington, late Manchester, drysalter, £267,000; Mr. Henry Barter, grocer, City, £149,000; Mr. Hy. Wm. Nevill, London, baker, £283,256; Mr. John Cadbury, cocoa, Birmingham, £43,773.

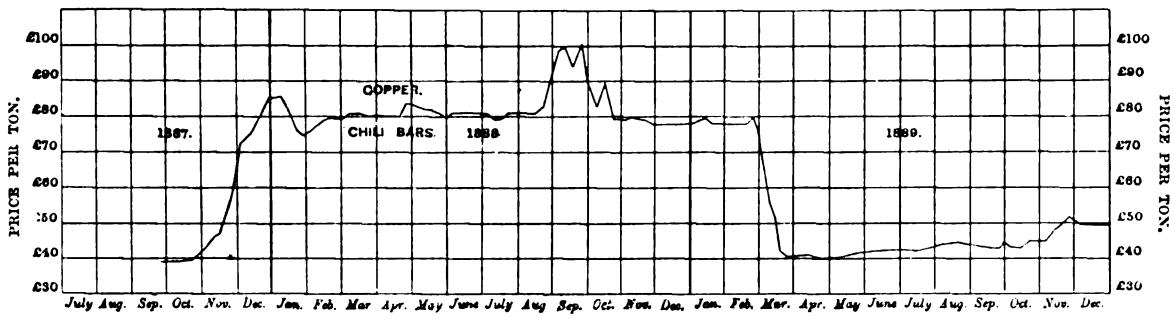
Liquor and Tobacco. — Messrs. James Jameson, Dublin, distiller, £489,352; Daniel Thwaites, Blackburn, brewer, £464,516; W. H. Crawford, Cork, brewer, £328,000; R. Prior, Hatfield, brewer, £171,180; John Thwaites, Blackburn, brewer, £164,000; W. T. Dibb, Hull, brewer, £162,936; John Turner, Chiswick, brewer, £154,422; George Wills, Bristol, tobacco manufacturer, £151,677.

Letters to the Editor.

THE GAS STOKERS' DISPUTES.

To the Editor of "Industries."

Sir,—Your correspondent "T. M.," in what, I have no doubt, he would term a reply to my letter to you, has very much avoided the question at issue. He has gone into those matters which I mentioned in my last were entirely apart from the main point. I quoted the manifesto of the men and confined myself to it, but your correspondent goes off on another tack, and he shows ignorance in addition. He states "the men were employed on certain terms; afterwards the directors of the Gas Company announced that they were about to alter those terms, adding that if the men did not agree to this alteration they might go." I never incline to hair-splitting, and I am content to take this assertion in a general way, but even then it does not bear any relation to facts. I quite understand that "T. M.," writing from Glasgow, has not quite the data to go upon that I have in London, but even this does not justify his recklessness. The directors proposed a bonus scheme, and allowed those to sign it who chose to do so. It is untrue, however, that they told those men to leave their employment who did not sign. Either "T. M." is ignorant of the main question, or else he is perverting the truth. It may, or may not, be true that I am the holder of obsolete ideas, as he says, but at any rate I have firm facts before I commit myself to statements The cause of the strike was given in my quotation from the resolution of the union. "T. M." asserts that observations on this point are beside the mark, but if this be the case I am not to blame, but the passers of the resolution.



The whole question resolves itself into whether Mr. Livesey may employ a "blackleg." He says "Yes," and so do I, and the whole of "T. M.'s" utterances do not touch the matter. A proof that the union was not affected by the bonus scheme was that the men who signed it were members of the union. This is evidence *primâ facie* that the signatories did not look upon it as a means of suppressing their powers. I quite admit the right of the stokers or any one else to form a union. So far as this is concerned there is no difference between "T. M." and myself, but we may perhaps dissent as to the mode of carrying it out.

Trade unionism forms a very wide subject of discussion, and in its general bearings does not come into this. If "T. M." cares to formulate his views on the subject separately I will reply to him, but such generalities should be kept apart from the special subject. No one has disputed the fact that the men have had a right to form a union any more than that they have a right to leave work when they care to give notice and to starve in consequence.

"T. M." says the position of the men is tenable. This is no argument, but merely a question of endurance. As far as things have gone it does not appear tenable, for funds are getting low, and public sympathy is nowhere. If the question of sentiment, which your correspondent so much objects to, is to be eliminated

CHART SHOWING THE PRICES OF COPPER FROM SEPTEMBER 1887 TO DECEMBER 1889.

we are brought down to the economic theory of obtaining the cheapest labour where it can be had, and Mr. Livesey has settled this with apparent satisfaction to himself.

Yours, &c.,

CHAS. W. RAUSCH.

London, 4th January, 1890.

COMMUNICATION BETWEEN ENGLAND AND FRANCE.

TO THE EDITOR OF "INDUSTRIES."

SIR,—In addition to the modes of crossing the Channel, of which you treated in your recent number, there was a project put upon paper somewhere about ten or twelve years ago which may be added to the list given, but, as I am writing from memory, I am unable to state who the author was. His proposal was to construct a submarine causeway to carry a line of railway, on which a long, wide, and heavy trolley was to run. On the trolley there was to be fixed a structure shaped like a barge, which contained the driving machinery (of compressed air) and also the passengers. The latter were to be admitted to water-tight compartments in the carriage, if such it can be termed, on the one shore, which was to be closed on them, and during the journey they were to be supplied from reservoirs of compressed air. It was arranged that, in case anything went wrong, the superstructure could be detached from the trolley by the engineer in charge, and the carriage-boat was then to "bob up serenely from below" and float on the surface of the water till help came. I need hardly add that this project never reached a stage beyond being put upon paper, but it deserves a place among some of the other curiosities to which you have referred.

Yours, &c.,

London, 28th December, 1889. T. C.

SAFETY APPARATUS FOR TRANSFORMERS.

TO THE EDITOR OF "INDUSTRIES."

SIR,—Perhaps you will allow me to make a few remarks in answer to your criticisms last week on the proposed use of these devices, and on their efficiency.

It appears from your remarks that you are not aware of the connections and arrangement of the apparatus, which have been found to work best in practice. These are extremely simple. The bottom plate, with the aluminium foil lying on it, is connected to earth; the attracting disc to the secondary circuit—in the centre if available—if not, to one side. The apparatus is set to act at a potential of between 300 and 400 volts from earth, and both theory and considerable practical experience show that, whether this potential be acquired by the secondary circuit as a result of a metallic contact with the primary or of a partial contact, or of electrostatic induction, the foil will certainly act. In fact it is impossible with this arrangement and a good earth connection to maintain a difference of potential from earth on the secondary circuit exceeding the limit for which it is set. It is also found by experience that after having blown one primary fuse and cut off one source of dangerous potential, the foil is not materially damaged, and is ready to act again and blow the other fuse if necessary, the foil merely starting a momentary arc. At the same time, so far as the 100 or 50 volts of the secondary circuit itself are concerned, the device puts on no earth at all, and this, I venture to think, from the point of view of fire risk, is a great advantage.

It is impossible within the limits of a letter to analyse all the various cases and combinations that may arise, but I think the foregoing will be found to answer your criticisms.

Yours, &c.

(For Drake & Gorham).

B. DRAKE.

66, Victoria Street, London, S.W.,
6th January, 1890.

Reviews.

ELECTRICITY IN MODERN LIFE. By G. W. de Tunzelman, B.Sc. London: WALTER SCOTT. 1889.

This is one of the first volumes of the Contemporary Science Series, in which it is promised that "the best that is known and thought in all the departments of modern scientific research," "all the questions of modern life," "the most recent researches in the knowledge of man, the past and present experiences of the race, and the nature of its environment," and a few other matters, "will be frankly investigated and clearly presented" by various writers, and will be edited by Mr. Havelock Ellis. The author of this little book must have needed no small courage to take his part in so ambitious a scheme. The first chapter deals with sticks of resin, pith balls, prime conductors; Thales and his amber turning up, of course, at the third line. Who will be the first to dare to relegate all this to the last pages of a book on electricity? A chapter on "Force Work and Power" is clearly written, but states that "for ordinary engineering purposes . . . the unit of work . . . is a foot-pound. . . . The absolute unit of work employed for all scientific purposes is the work done by a force of one dyne acting in its own direction through a distance of one centimetre. This unit of work is called an erg." This suggests a marked and somewhat unfavourable comparison between "engineering" and "scientific" purposes, but the reader is not enabled to judge of the comparative utility of the systems, for, in his anxiety to make the book popular, the author has not only omitted to express the erg and dyne in intelligible language, but has not even given the values of the centimetre and gramme in English units. The absence of figures is remarkable; there are no formulæ, and hardly any numerals in the book besides dates, and the author has so thoroughly sunk his mathematical abilities as to refrain from expressing Ohm's law in symbols. While at such pains to be popular, it seems a pity to deal with tubes, instead of lines of force. The history of electrical measurements and of the telegraph are admirably written, the former being necessarily somewhat dry, but the latter most interesting. Two good chapters on the telephone include descriptions of the phonograph and graphophone, with the apology that they are closely allied to the telephone. No allusion is made to the original determination of the ohm, but the "legal ohm" is referred to in several places. It is a pity that this misleading name should have survived for more than five years. In a popular work of this kind an attempt should be made to give some faint idea of the value of the electrical units—*e.g.*, the resistance of iron telegraph wire is about 12 ohms per mile, an electric bell battery gives about one and a half volts per cell, the current used for a glow lamp is generally between half an ampere to one ampere. In describing the manufacture of glow lamps "running on the pumps" is confused with "flashing," and Lodyguine's name is misspelt. The continual use of the expression "e.m.f." is to be regretted, the word "pressure" being quite suitable for the purpose of this book, which, if not quite up to the programme of the Contemporary Science Series, is excellently adapted to give an accurate idea of the applications of electricity to daily life; and we can recommend it to those who have no previous knowledge of the subject.

THE FEDERATION OF THE BRITISH EMPIRE. By the Rt. Hon. Sir George F. Bowen, G.C.M.G. London: KEGAN PAUL, TRENCH, & Co.

THE FUTURE OF THE EMPIRE. By Alexander Gordon. London: SIMPKIN, MARSHALL, & Co.

We have on several occasions directed the attention of our readers to the important question of Imperial Federation, especially in its bearings on the industries and commerce of the country, and we promised to place before them both sides of the question. On such an important matter, however, a considerable amount of literature is likely to appear, and we may save our space if we occasionally bring some of it before the notice of our readers. The two pamphlets mentioned at the head of this notice take opposite sides on the question, and that is one reason why we have placed them together. Sir George Bowen is an ardent Federationist, and he quotes with decided approval Lord Rosebery's opinion that Imperial Federation "is a cause for which any one might be content to live; it is a cause for which, if need be, any one might be content to die;" and his long experience as a Colonial Governor gives great weight to his opinions. The only fault we have to find with the pamphlet is that it is written in a somewhat egotistic style, and brings the personal services of the author somewhat too prominently to view. Nevertheless it presents a very good view of his side of the case.

The other side is presented by Mr. Gordon, who shows some of the difficulties in the way, but it seems to us that his conclusions are not necessarily opposed to Federation. After pointing out what he considers the true use of colonies, and assuming that they must ultimately become independent States, he advocates alliance rather than federation—an alliance from which the greatest of all English-speaking people, the citizens of the United States, should not be excluded. We might have a Federation of the British Empire in which the various elements were as independent as the States in America, and then an alliance with the United States. The Imperial Federationists have not drawn out any exact scheme whereby their wishes are to be carried out, but are willing to leave the details to be developed with events, and these might even tend in the direction indicated by Mr. Gordon. In any case the various aspects of the subject should be carefully considered, and the two pamphlets we have mentioned are well worthy of perusal.

THE FORTH BRIDGE

THE Twenty-seventh Quarterly Report of Inspection by Major-General Hutchinson, R.E., and Major Marindin, C.M.G., R.E., of the works in progress for the construction of the bridge over the River Forth has just been published. We append it in full:—

We have the honour to report, for the information of the Board of Trade, that in compliance with the instructions contained in the order of the 26th October, 1882, and in accordance with the provisions of the Forth Bridge Railway Act of 1882, we have made our twenty-seventh quarterly inspection of the works for the construction of the bridge over the Firth of Forth at Queensferry, now nearly completed.

Both the central girders of the two large spans have been connected together during the last quarter, and the bridge can now be traversed from end to end.

All work of a temporary character has ceased, and the work done upon the permanent structure and its present state are briefly described below.

SOUTH QUEENSFERRY.

South Cantilever.—The erection and riveting of this are practically completed.

North Cantilever.—The main members of this cantilever are complete, and with the exception of a few feet of the wind fence, and footpaths in bay 6, the whole of the internal viaduct is in place, and nearly the whole is riveted.

South Central Girder.—With the exception of the footpaths, and a few feet of the wind fence, the whole of this girder is erected, and very little of the riveting remains to be done.

The riveted work at South Queensferry now amounts to 15,900 tons, an addition of 600 tons during the quarter, as compared with 1,350 tons during the previous quarter, leaving 130 tons to be completed.

INCH GARVIE.

South Cantilever.—This is completed.

North Cantilever.—The whole of the main members are in place, and practically the whole are riveted, and with the exception of a small portion of the wind fence and footpaths of bay 6, the internal viaduct is completely built and riveted.

North Central Girder.—With the exception of the wind fence, footpaths, one-half of the flooring, and a small portion of the bracing, the whole of this girder is erected, and about three-fourths of it are riveted.

The total quantity of riveted steel work at Inch Garvie is 18,402 tons, an addition of 850 tons during the quarter, as compared with 1,400 tons during the previous quarter, leaving 320 tons to be completed.

NORTH QUEENSFERRY.

South Cantilever.—This is completed.

North Cantilever.—With the exception of the bracing between the struts in bay 6, the whole of the main members are erected, and very little of the riveting remains to be done.

The flooring of bay 6 of the north cantilever, and the footpaths and wind fence of bay 6 of both cantilevers, are unfinished, but with these exceptions the whole of the internal viaduct is erected, and nearly the whole is riveted.

The total quantity of riveted steel work at North Queensferry is about 15,750 tons, an addition of 650 tons during the quarter, as compared with 1,250 tons during the previous quarter, leaving 280 tons to be completed.

PERMANENT WAY.

South Approach Viaduct.—All the longitudinal sleepers are in place, and the rails laid and nearly all screwed down.

South Queensferry.—The teak and pine blocks in the troughs under the sleepers are laid from the end of bay 5, south to the end of bay 4, north cantilever, and about 200 feet of the sleepers are laid.

Inch Garvie.—The teak and pine blocks are laid from the end of bay 4 south to the end of bay 4, north cantilever.

North Queensferry.—The teak and pine blocks are laid from the end of bay 3 south to the middle of bay 4, north cantilever, and the longitudinal sleepers are laid from the vertical columns to the end of bay 3, on the south cantilever.

North Approach Viaduct.—With the exception of a length of 80 feet, all the sleepers are in place, and the rails, except for a length of 160 feet, are laid, but not screwed down.

GENERAL REMARKS.

Steel Work.—With the exception of that for the footpaths and the wind fence for the north central girder, the whole of the steel for the bridge has been drilled and fitted.

Masonry.—The coping of the cantilever piers is all that remains unfinished.

Weather.—The weather during the past quarter has, on the whole, been very favourable considering the season of the year.

IMPROVED CHAIR AND SLEEPER FOR RAILWAYS.

CONSTRUCTED BY THE CHAIR AND SLEEPER COMPANY, WIDNES.

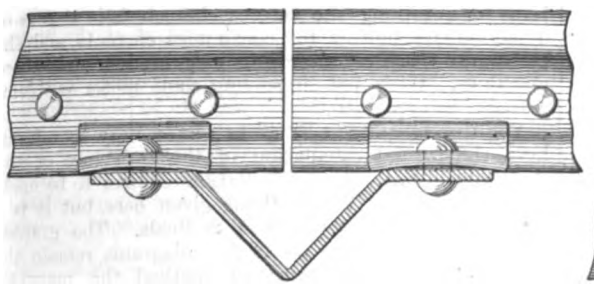

FIG. 1.

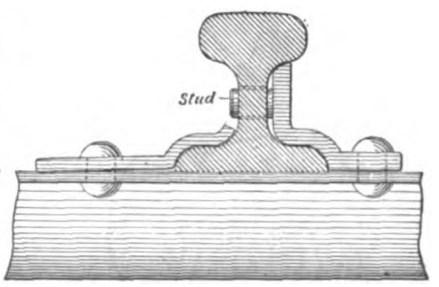

FIG. 2.

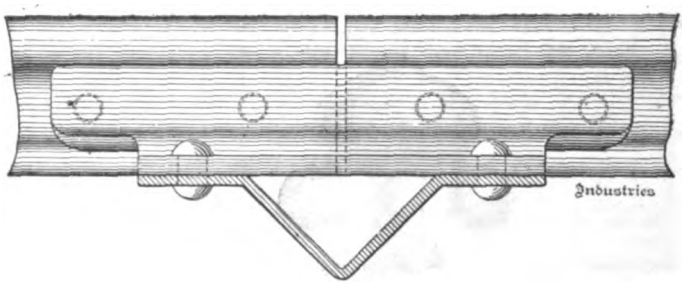

FIG. 3.

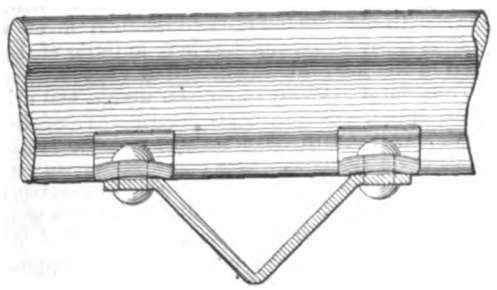

FIG. 4.

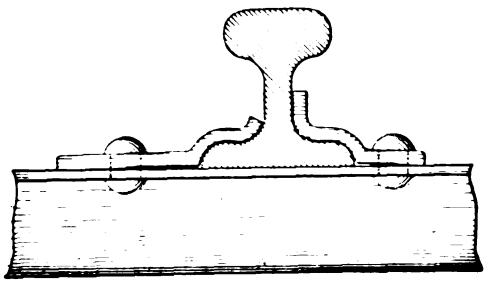

FIG. 5.

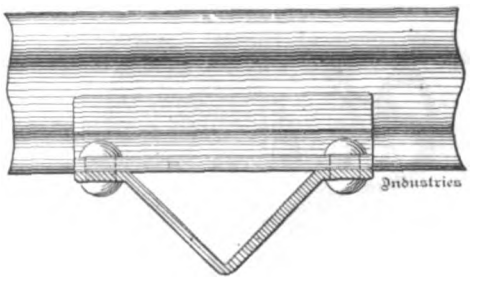

FIG. 6.

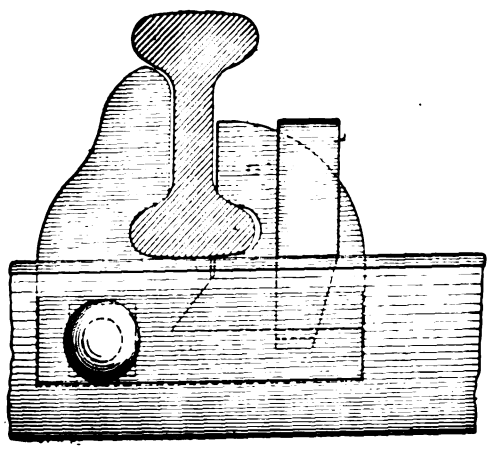

FIG. 7.

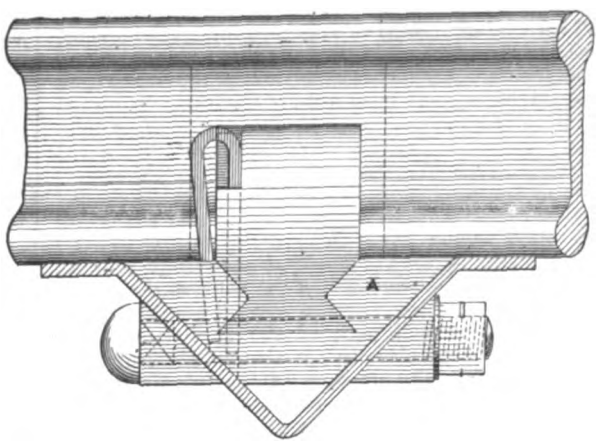

FIG. 8.

The highest wind pressures recorded at Garvie Castle were on November 2nd, 1889, when the large gauge showed a pressure of 12lb., the small gauge a pressure of 34lb., and the revolving gauge a pressure of 27lb.

The average number of men employed per diem during the quarter has been 1,795, and the number employed on November 23rd was 1,585.

We regret to have to report that, even with this reduced number of workmen, there have been four fatal accidents, one of which, on September 12th, when a riveter, John Aitkin, aged 16, was killed, was due apparently to carelessness in the fixing of a stage upon which he was working. Two others, on the 18th and 24th September, are stated to have been due to the falling of pieces of wood from a height, which should not occur if proper care be taken. In the fourth case a rigger unfortunately lost his balance and fell into the water, receiving fatal injuries.

The result of measurements taken on November 26th shows that under the central girders there is a clear headway in no case less than 1ft. 1in. above that specified in Section 5 of the Forth Bridge Act.

In conclusion, we can state that, so far as it is possible to judge from a periodical inspection, the high character of the work is being maintained to the end.

IMPROVED SLEEPER FOR RAILWAYS.

AN improved form of chair and sleeper for light and heavy railways has just been brought out by the Chair and Sleeper Company, Limited, Widnes, Lancashire. The sleeper and rail fastenings intended for light railways and tramways are shown in Figs. 1, 2, 3, 4, 5, and 6. It will be seen from Figs. 2 and 3 that only one fish-plate is used at the joint, this fish-plate being provided with studs slightly tapered, which take the place of the fish-bolts ordinarily used. All the clips, both for the joint and intermediate sleepers, are riveted, and for colliery and other light lines, where the vibration from the traffic will be practically *nil*, this form of construction is at once simple and effective. In Figs. 7 and 8 is shown a special form of chair and sleeper intended for double-headed rails, such as are ordinarily used on our main lines. It will be seen that the chair base A, Fig. 8, which is of malleable cast iron or mild steel, is V-shaped, and is held in position by a bolt with lock nut. In place of the ordinary wooden key the rail is fixed in position by a sliding jaw, which is forced against the rail by a spring key shown on the left of the chair in Fig. 8. As regards the sleeper itself, it will be seen that for light and heavy railways it is of the same section, only for heavy work the sleeper plate is made thicker. The wedge shape of the under part of the sleeper enables it to embed itself firmly into the ballast in such a way as to prevent any shifting, thus saving expense in ballasting, which is an important item in the maintenance charges of our chief railways.

MINING ENGINEERING IN 1889.

There have been but few achievements in the mining branch of engineering to render the year 1889 remarkable. Genuine progress has no doubt been made; but there have been no startling inventions, no great advances made in the application of recently required knowledge—nothing, in short, which can be properly described as a distinct step forward, or as an event capable of serving as a landmark in the history of mining science or practice.

In reviewing the work of the past year we naturally turn first to the achievements of the electricians, and are somewhat disappointed to find that, while fresh developments have been made in nearly all directions, mining has been exceptionally neglected. The important problem of a miner's safety lamp has not been solved. It has, indeed, judging from the results of experiments made publicly known, advanced no nearer to solution. In the matter of the electrical ignition of blasting shots we seem to have retrogressed, in spite of the fact that powerful electric currents are now at the disposal of the mining engineer at almost every pit. This is a direction in which inventive talent may profitably be turned in 1890. The year is, however, not altogether a blank in electrical progress for the mining world. In our issue of February 8th we described and illustrated an electric locomotive which, though introduced in 1888, underwent its practical tests in the year just ended; and later, on the 15th November, we illustrated an electric hoist for mines designed by the Brush Electric Company, of Cleveland, Ohio, U.S.

In the work of coal-getting there is but little scientific progress to report. Of improvements in coal-cutting machines we have heard practically nothing. But here again the year has not been wholly void; for a movement was set on foot with a view to bring back to this important subject the attention which has of late been diverted into other directions. To effect this purpose, the North of England Institute of Mining and Mechanical Engineers have appointed a committee to report upon the use of coal-cutting machinery, and to offer suggestions for its improvement and adoption. For the "falling" of coal—that is, the breaking down of the under-cut seam—nothing new has been made known; and it does not appear that much progress has been made in the application of those machines and apparatus which were introduced in the previous year. There has been a lull, too, in the invention of flameless explosives, so numerous in 1887 and 1888. But the use of some of these has been considerably extended.

In the field of metal mining, inventive genius has been scarcely more active. The extraction of gold from its ores seems to have received most attention in the past year. It cannot, however, be said that much has been accomplished even in this direction. We have noticed some further developments of known processes and some new applications of principles which may develop into something important later. In our issue of the 27th September we described a system for the treatment of gold ores, especially suitable for the pyritiferous sorts, seen for the first time in England at the works of Messrs. Hornsby & Sons, at Grantham. This process, devised by R. L. Cousens, is a combination of the electrical and the chlorination methods. In our issue of the previous week we had described the latest development of what is known as the "Cassel" gold extracting process, a system specially applicable to poor and refractory ores. Beyond these, there is nothing specially worthy of note. For some remarkable examples of construction in mining machinery, see *Industries*, Vol. VI., No. 138, and Vol. VII., No. 170.

THE "EXACT" GOVERNOR.

CONSTRUCTED BY MESSRS. SCHAFFER & BUDENBERG, MANCHESTER.

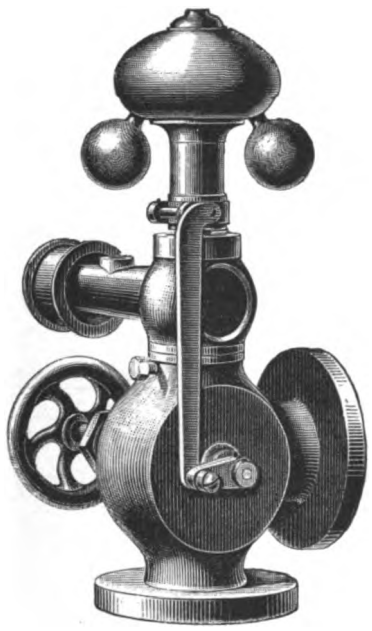

FIG. 1.—GENERAL VIEW.

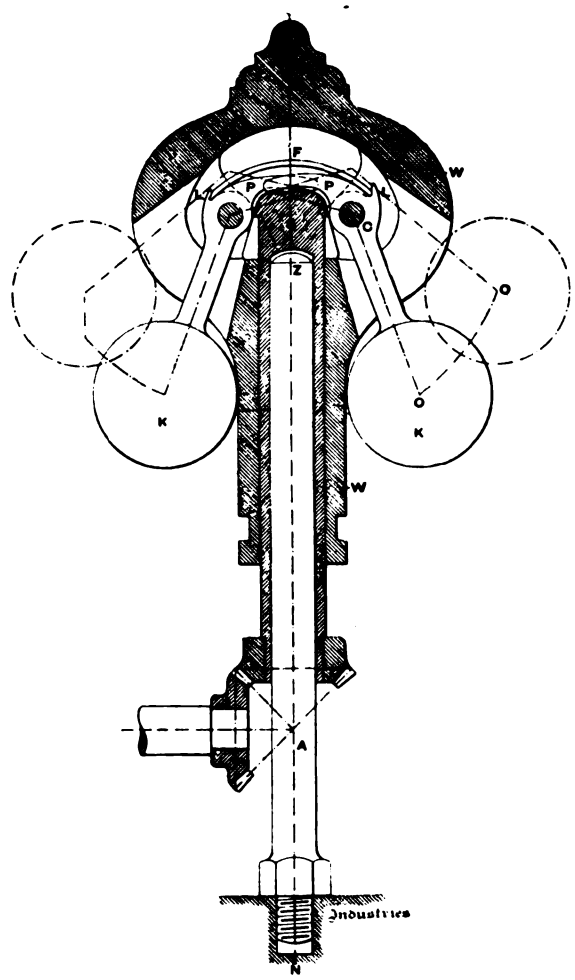

FIG. 2.—SECTION OF GOVERNOR.

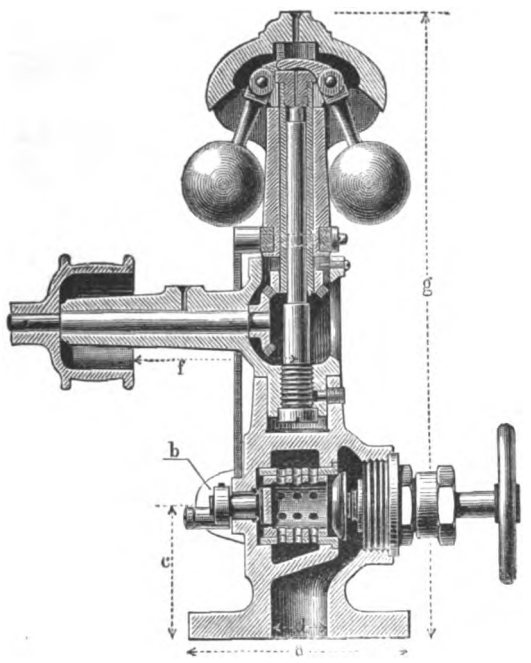

FIG. 3.—SECTION OF GOVERNOR AND STOP VALVE.

THE "EXACT" GOVERNOR.

WE give illustrations in Figs. 1, 2, and 3 of a new design of high-speed governor which is being put upon the market by Messrs. Schäffer & Budenberg, of Manchester, London, and Glasgow. Fig. 1 gives a general view of the governor, Fig. 3 is a sectional view, and Fig. 2 is an enlarged sectional view of the governor proper. The curves which are described by the balls in their rise and fall are approximately part of a parabola. By reference to Fig. 2 it will be seen that the fulcrum C of each of the pendulous levers are situated on the sliding weight W. A short cam P is connected to the lever, extending from the fulcrum towards the axis of the governor, and rests upon a shaft S, which revolves upon the spindle Z. The latter serves to support the governor, while the shaft S has only a rotary, and not any vertical, movement. In parabolic governors as ordinarily made, the actual path O O^1 of the governor-ball centres coincides with the parabola only at one point—viz., when the balls are in their lowest position O—when it forms a tangent to the parabola. In the new governor, on the contrary, the ratio between the length of the pendulous levers O C and the dimension O X is such that the actual path of the governor forms a tangent to the parabola when the balls are in their middle position. The distance of the fulcrum C from the axis of the governor is constant, and, in consequence, the end X of the short arm C X slides a little on the top of the shaft S. If a straight line be drawn from X perpendicularly to the path O O^1 it will intersect the path in the middle, so that X may be considered to be the centre of curvature for the parabola touching the side of the path between O and O^1. A governor constructed in this way rises from its lowest to its middle position as soon as its normal velocity of equilibrium has been attained, and will form, in its higher positions, a near approach to a perfectly isochronous governor. There are, however, two defects to be overcome. In the lower half of the lift the governor has not sufficient stability to be useful, while in its upper half its sensitiveness is excessive, and unfits it for practical use. In order to obtain the required stability and sensitiveness in all positions, a spring F is placed between the two pendula, being arranged so that the ends of the spring press symmetrically on suitable projections. The spring forms a sort of arch between the upper ends of the pendula, and, as the balls are raised, a certain tendency to compression in the spring is established, the arch being flattened or bulged proportionately to the lift of the balls. A support for the governor is arranged near the top upon the fixed steel spindle Z. The friction of the governor is thus reduced to a minimum, and the wear of the toothed wheels is almost completely obviated. From this cause the risk of slipping in the belt is reduced, as the governor is so easily actuated. The throttle valve is of the rotary type, a complete equilibrium being thus established, and only a slight resistance to the motion of the governor is made. The stuffing box on the throttle valve spindle is replaced by a conical valve seating kept tight by the steam pressure in the valve. The latter is combined with a stop valve, and the lateral arm supporting the driving pulley can be adjusted to suit any conditions. The governor is made in six sizes, the smallest having a ¾in. valve, a uniform speed of 300 revolutions being adopted. It is of a good appearance, and we understand that the price is moderate.

GRAPHIC CONSTRUCTIONS FOR DYNAMOS AND MOTORS.

BY PROFESSOR ROBERT H. SMITH.

I.

IT is proposed here to describe certain easy constructions for obtaining the various characteristic curves of dynamos and motors for continuous currents, and the assistance these constructions give in designing these machines. Their use in solving some motor problems will also be explained.

For this purpose it is quite unnecessary to set out here the formal calculation of the resistance of the magnetic circuit. That calculation requires to be made by any one using the methods given here, but it is a matter independent of these methods. The graphic constructions and the use of the diagrams remain the same by whatever theory or method the magnetic resistance be calculated. In commencing the diagram one has to use a pair of quantities which have been found either by such a calculation or else directly by special experiment; but it would quite unnecessarily complicate the symbolisation required if we were to express these two quantities here in terms of the dimensions of the machine on which they depend.

Thus, for a machine of a given design, and driven at a given speed, a definite curve describes the relation of the e.m.f. generated in its armature and the ampere-turns exciting its magnets. This curve starts with a certain initial slope and rises asymptotically to a certain limiting height, where it becomes parallel to the axis along which the ampere-turns are plotted. This initial slope is a matter of easy calculation (to a degree of approximation sufficient for the practical purposes of design). The calculation involves the dimensions of the machine, exclusive of the number of turns and the currents in the magnet coils, the speed, and in a slight degree the "initial permeability" of the quality of iron used. This slope is, in fact, proportional to the speed, to the number of coils in the armature, to the average cross-section of the magnetic circuit, and to the average "initial permeability," the average being taken in the proper way right round the magnetic circuit, including the air and other non-iron parts of the circuit: while it is inversely proportioned to the length of this circuit, and also depends on the amount of magnetic leakage, decreasing as that leakage increases. The limiting e.m.f. towards which the curve rises asymptotically is proportional to the speed, to the number of armature coils, to the armature cross-section, and to the maximum intensity of magnetic induction that can be obtained in the armature section by raising the magnet ampere-turns to an indefinitely high amount. This latter intensity, of course, does not depend on the speed. Neither does it depend on the "air spaces"; nor on the quality of iron in the magnet cores or pole pieces, nor the dimensions of these; nor even upon the coefficients of magnetic leakage. It depends only on the construction of the armature itself, and chiefly on the quality of the iron in the armature core. To a certain degree, which, however, is small in well-constructed machines, it is affected by the armature cross-magnetisation and self-induction, and this again depends on the speed and armature current. It and the initial permeability being fairly well known from the experimental researches of Hopkinson and others, the above two fundamental elements of the diagram can be calculated from the above-mentioned data with, at any rate, a certain approximation to accuracy (the roughness of which depends only on our knowledge of the degree in which magnetic leakage, armature cross-magnetisation, and self-induction will affect the result); or else the two may be determined by experiment if the skeleton of the machine be already made.

From these elements the diagram may be completed by graphic construction. The construction may be made according to either of three laws. The first is Fröhlich's law, illustrated in Fig. 1; the second, Lamont's law, according to which Fig. 2 is drawn; the third is shown in Fig. 3. The first is a rough approximation to the actual truth, as tested by experiment; the second is a closer approximation, and is equally easy for graphic construction. Both of these laws or formulas were framed in order to represent the relation between the increasing ampere-turns, or the "magneto-motive force," on an electromagnet, and the consequent increasing magnetic intensity in the field of the magnet. But they may also be used for the purpose here stated with accuracy enough for many practical purposes.

From the origin (point 1) is plotted upwards 1, 2 = E, the maximum limit of the e.m.f. From 2 is drawn a horizontal line, and from 1 is drawn 1, 3 at the "initial slope" of the curve, these two lines intersecting at point 3. Note that since both E and the slope $\frac{1}{2}\frac{2}{3}$ are directly proportional to the speed of revolution, therefore the horizontal distance 2, 3 is independent of the speed. Thus, if a number of diagrams be drawn for the same machine at various speeds, all the

GRAPHIC CONSTRUCTIONS FOR DYNAMOS AND MOTORS.

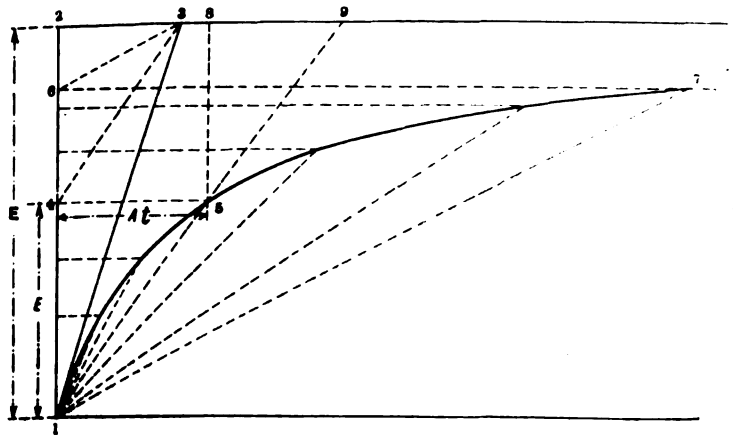

FIG 1.

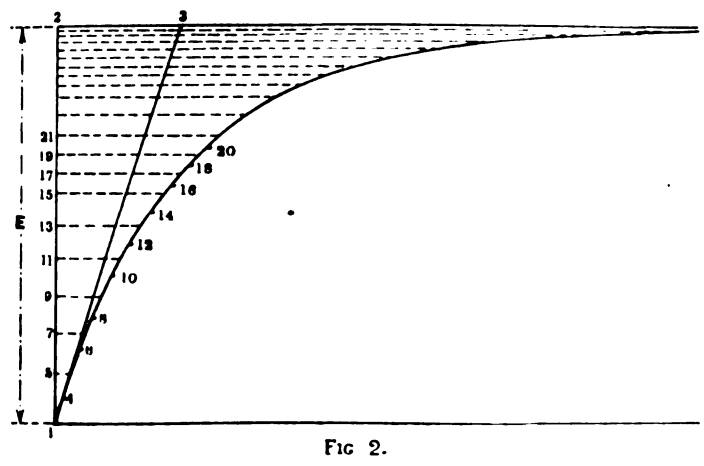

FIG 2.

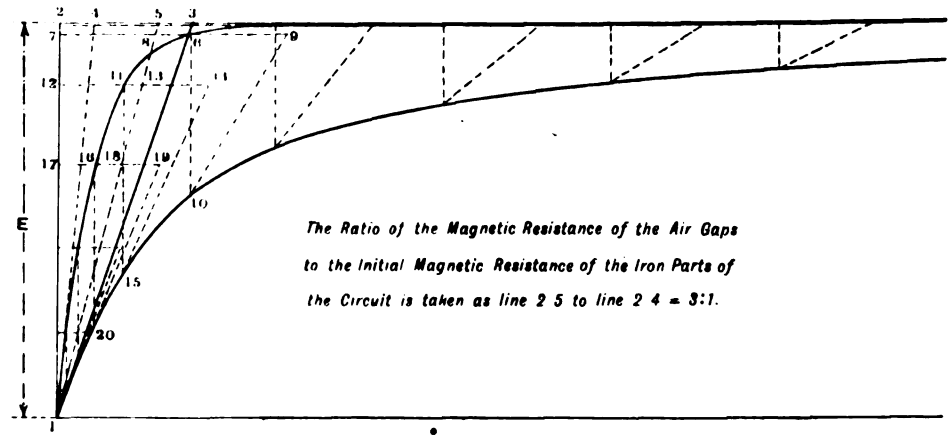

FIG. 3.

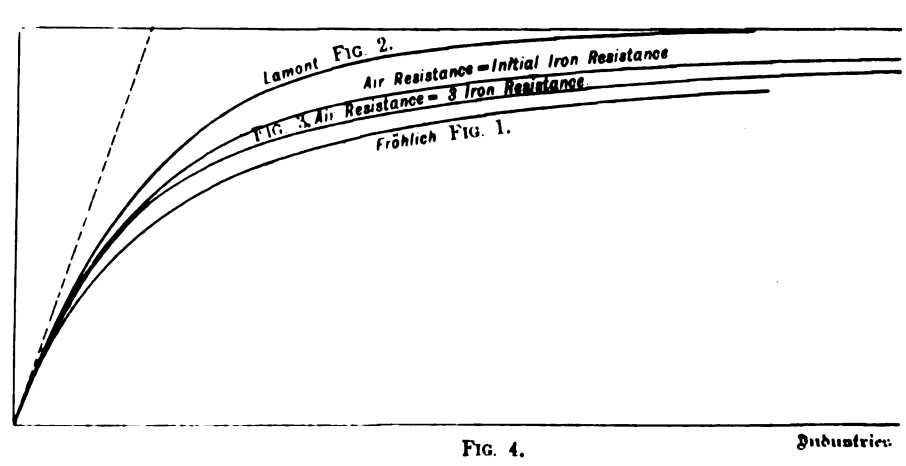

FIG. 4.

points 3 for those different diagrams will lie on the same vertical line.

In Fig. 1 (Fröhlich's law) the points of the curve are obtained thus: For any e.m.f. or height E = 14 draw the horizontal 4, 5, and parallel to 4, 3 draw from the origin the line 1, 5 to intersect 4, 5 in point 5. This point 5 so found is a point in the curve. Thus point 7 is obtained by drawing 1, 7 parallel to 6, 3 to meet the horizontal through 6. Obviously, another way of carrying out the same construction is the following: For any horizontal ordinate 4, 5 = 2, 8, set off 8, 9 = 2, 3 along the top edge of the diagram. Through the origin draw 1, 9, intersect the vertical line 8, 5 in point 5. This point 5 is a point in the curve.

In Fig. 2 (Lamont's law) the construction proceeds as follows: On the vertical axis choose any points 5, 7, 9, 11, 13, 15, 17, 19, 21, &c., these points being taken closer together the higher or nearer 2 they are. From point 4, taken on line 1, 3 at mid-level between 1 and 5, draw 4, 6 parallel to 5, 3, the line being carried on to 6 at mid-level between 5 and 7. Then draw 6, 8 parallel to 7, 3 as far as 8 at mid-level between 7 and 9. Then draw 8, 10 parallel to 9, 3 as far as 10 at mid-level between 9 and 11. Then draw 10, 12 parallel to 11, 3 as far as 12 at mid-level between 11 and 13. This process is continued to the extremity, or, rather, as far as it may be desired to draw the curve. The points successively obtained are numbered in Fig. 2 up to 20 and 21. For instance, the element 18, 20 is drawn parallel to 19, 3 as far as point 20 at mid-level between 19 and 21. These short straight lines are tangents to the true curve, which should be drawn inside them so as to touch all of them. The curve, therefore, does not really pass through the points 4, 6, 8, 10, &c., but through nearly the middle points of the lines between these. But in practical work, provided the points be taken sufficiently numerous, it makes no appreciable difference whether the curve be drawn through points 4, 6, 8, &c., or tangent to these lines. It is, however, just as easy to draw the curve correctly (tangent to the lines) as incorrectly (through the points).

Figs. 1 and 2 have been drawn with the same asymptotic height E and the same initial slope. They show at a glance what a large difference there is between the two laws. It is curious that some electrical engineers, who admit Lamont's law to be the more accurate, still recommend the use of Fröhlich's because of what they imagine to be its superior simplicity. Its algebraic expression looks certainly simpler, or is, at any rate, more elementary; but graphically the one is quite as easy to deal with as the other.

Neither of these curves represent very truly the "total" or "internal" characteristic of a dynamo. If the whole of the magnetic resistance of a dynamo were due to the resistance of the iron parts of the circuit, very probably Lamont's rule, Fig. 2, would represent the result very accurately. But the resistance of the circuit is the sum of two parts—one that of the iron increasing according to a definite law with the magneto-motive force, the other that of the air gaps and insulating material which remains constant throughout the whole range of magneto-motive force ever applied. In Fig. 3 this difference between the two parts is allowed for. Fig. 3 is drawn so as to have the same initial slope and the same asymptotic height as Figs 1 and 2.

If the whole magnetic resistance were constant, the curve would be a straight line. Let 1, 5 be the straight line characteristic which the dynamo would have if its whole magnetic resistance were due to the air gaps and the insulating material and wire in the armature. Let 16, 11, 6 be the Lamont curve characteristic which it would have if there were no magnetic resistance except that due to the iron in the magnet and armature cores, the line 14 gives the initial slope of this curve.

The initial slope of the integral curve 20, 15, 10, compounded from these two, is given by line 1, 3, the tangent from the vertical being the sum of the tangents of the two other lines—that is, 5, 3 = 2, 4. On any horizontal 7, 9 cutting the curve in point 6, set-off 6, 9 = 7, 8. Through the origin draw 1, 9 to cut the vertical through 6 in point 10. This 10 is a point in the new curve. Similarly make 11, 14 = 12, 13; draw 1, 14 to cut vertical through 11 in 15. Similarly make 16, 19, = 17, 18; draw 1, 19 to cut vertical through 16 in point 20.

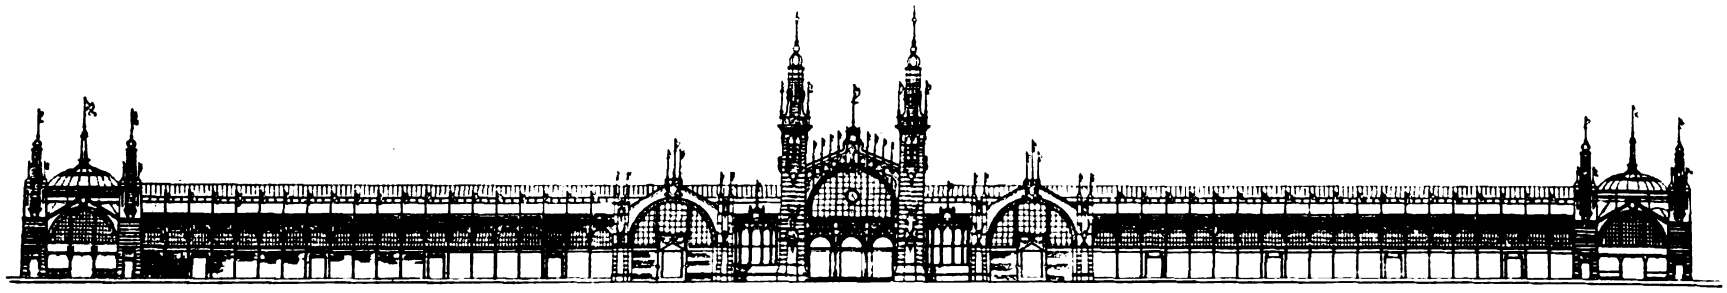
Fig. 3 has been drawn on the assumption that the *initial* magnetic resistance due to the air gaps, &c., is *thrice* that due to the iron in the circuit. The uppermost part of the Fig. 3 curve is very nearly the same as if it were drawn out according to the Frölich formula, the dimension 2, 5 in Fig. 3 having the same function as 2, 3 in Fig. 1, so far as this part of the curve is concerned.

In Fig. 4 the three curves of Figs. 1, 2, and 3 are reproduced, so as to make the comparison between them more easy. In Fig. 4, a fourth curve is drawn, by the construction of Fig. 3 with the initial iron resistance equal to the air resistance.

The elements for the construction of these curves can, as already said, be found by simple calculation. If it be desired to find them from direct experiment on the already built dynamo, two co-ordinated measurements of ampere-turns and e.m.f. are sufficient for Fig. 1. For instance, if from these two tests the points 5 and 7 can be plotted, then in order to find 3 all that is needed is to draw from 4 and 6 two lines parallel to 1, 5 and 1, 7. Their intersection gives 3, from which the rest of the curve may be drawn.

For Fig. 2 four measurements are needed, giving two pairs of points, the points of each pair lying near each other. For example, if 8, 10 and 18, 20 could be plotted from four such measurements; then, taking 9 and 19 at the mid-levels between these pairs of points, draw from 9 and 19 two lines parallel to 8, 10 and 18, 20. They will meet in the point 3, from which the rest of the curve can be drawn. In this case the construction furnishes a check on the accuracy of the operation, for, after finding the point 3, the curve drawn by its help outwards from the origin may not pass through the already determined points if either the formula be wrong or the measurements or plotting be incorrect.

The construction of Fig. 3 has the disadvantage that the elements for its complete construction are not so easily obtained from points plotted to represent a few isolated experiments. Nevertheless, it seems to give the actual shape, as found from dynamo tests, more accurately than any other formula capable of simple graphic manipulation.



Having obtained this curve co-ordinating E, the whole electromotive force generated in the armature and the ampere-turns round the magnets, it can be easily converted in the case of a series dynamo into a curve whose horizontal ordinates are the currents by simply changing the horizontal scale in the ratio of the number of turns in the magnet coils. It then becomes the "internal characteristic" of a series dynamo. The actual geometrical slope at any point of either this or the original curve depends entirely, of course, upon the scales that have been selected as convenient for the e.m.f.'s, and for the currents or ampere-turns.

To deduce from this latter the "external characteristic" of the series dynamo co-ordinating the external e.m.f. between the terminals and the current requires only a very simple and well-known modification. Through the origin a straight line is drawn at a slope representing the internal resistance between the terminals, and the heights of the new curve are measured between this line and the "external characteristic" curve. Where the latter is parallel to the internal resistance line, the external characteristic becomes horizontal; that is, this point gives the maximum external e.m.f. and the corresponding current. These constructions are well known, and are not, therefore, here illustrated by a diagram.

(To be continued.)

THE EDINBURGH EXHIBITION, 1890.

General Elevation of the Main Building.

THE EDINBURGH EXHIBITION, 1890.

The idea of having an International Exhibition of Electrical Engineering, General Inventions, and Industries, at Edinburgh, was first brought forward about six months ago, it being thought that the completion of the Forth Bridge would attract a large number of tourists to Edinburgh during the coming summer, and that an Exhibition of a scientific character would be a fitting celebration of this event. The popularity of the undertaking is proved by the rapidity with which a large guarantee fund has been raised and all preliminary arrangements made. The Exhibition has, we understand, received the official recognition of the French Government, and a large number of exhibits are to be forwarded from Paris, including the whole of the Edison collection. As we explained in our issue of the 1st November, a site of ninety acres has been secured in a commanding situation near Merchiston, to the south-west of the city, which has the advantage of being in immediate proximity to two railways, each of which will have a special station within the grounds. There are to be two main buildings, one of which will be devoted entirely to the electrical exhibits and machinery in motion, and will be separated from the other by the South Side Suburban Railway, thus removing all objections to the noise of the machinery being heard in the concert hall and other parts. The two buildings are connected by a covered way, crossing the railway by a substantial wooden bridge, and midway between an annexe will probably be erected. The building for general exhibits, which is 700ft. by 200ft., is approached from the main entrance by a handsome iron bridge crossing the Union Canal. The general character of the design of the main building is that of the French Renaissance, the towers being, as has become almost universal in Exhibition buildings, somewhat Moorish. The engineer and architect-in-chief is Mr. W. Allan Carter, M.Inst.C.E., and his assistants are Mr. Frank W. Simon, architect, and Mr. Penman, C.E.

The space is occupied by the main building, the machinery hall, which is about 700ft. long by 150ft. wide, the boiler annexe, and an additional annexe containing a lecture hall and space for exhibits. In the grounds there are, besides a recreation park for football, &c., a panorama, Japanese village, a lighthouse, kiosks, numerous cafés, an exhibitors' club, electric launches on the canal, a working model of the patent ship railway (designed by Mr. William Smith, harbour engineer, Aberdeen), an electric railway, and the ubiquitous switchback. The space for outdoor exhibits is practically unlimited, as the lands adjoining are available should extension be necessary. The machinery hall and annexes are connected with the main building by a covered way.

A special feature of the Exhibition will be the provision of a lecture hall, to be utilised for the meetings of the Institution of Electrical Engineers and other kindred societies which have arranged to visit Edinburgh this year. Popular lectures are also to be delivered at frequent intervals, with a view to making use of the collection of electrical and other appliances which will be brought together, and thus giving the Exhibition an educational value beyond that of many recent undertakings of a similar kind. The offices of the Exhibition are at 40, Frederick Street, Edinburgh, and 3, Queen Victoria Street, London, E.C. The general management of the Exhibition is in the hands of Mr. Samuel Lee Bapty, who has had extensive experience in this form of catering for public amusement and edification.

In consequence of the representations of the Electrical Section of the London Chamber of Commerce, the Executive Council have decided to grant space to exhibitors free of charge unless the receipts of the Exhibition fall short of the amount of the expenses. This concession will apply retrospectively to all applications for space, and is an important and thoroughly just change in Exhibition arrangements. It will doubtless establish a precedent for the executive councils of future Exhibitions. Upwards of 150 electrical exhibits will come from France, while the Italian and Austrian exhibits will be specially extensive. In general inventions it is expected Japan, China, and India will be represented largely. The leading railway companies have promised exhibits of railway appliances. Among the electrical exhibitors are Sir William Thomson; W. H. Preece; Edison; General Post Office; Edison-Swan Company; Laing, Wharton, & Down; Anglo-American Brush; Paterson & Cooper; United Electrical Engineering Company; King, Brown, & Co.; Mavor & Coulson; Sir Wm. Vavassour, Ld.; Elmore Copper Depositing Company; Thomson-Houston; Electric Welding Company; Newall Engine Company; Robey & Co.; Electric Traction Company; Ernest Scott & Co.; Ronald Scott; Woodhouse & Rawson; Butler, Jobson, & Co.; W. T. Glover & Co.; National Telephone Company; Consolidated Telephone Construction Company; Colonel Gouraud; Gent & Co.; Exchange Telegraph Company; and the Eastern Telegraph Company. The Decauville Company will show a narrow gauge electric railway. Messrs. Immisch & Co. will provide by arrangement with the Executive Council a service of electric launches on the Union Canal between Fountain Bridge and the Exhibition. Boats will leave either end of the route every ten minutes. The sums already paid by refreshment contractors and other concessionaires place, it is said, the Exhibition on a solid financial basis, the sums so accruing being sufficient to defray the cost of the buildings, &c., thus leaving the admission receipts to pay the working expenses. It is to be specially noted that applications for space finally close on Wednesday, the 15th January, the time having already been extended.

THE SOCIETY OF CHEMICAL INDUSTRY.

At the meeting of the London Section, held on Monday, 6th inst., Mr. C. T. Kingzett, F.I.C., F.C.S., read a paper on "Peroxide of Hydrogen and its Uses," in which he described several series of experiments which he had undertaken with a view of ascertaining the best means of preserving solutions of this compound from decomposition. The method which he adopted consisted in first determining the amount of iodine by titration with standard hyposulphite, which was liberated by the solution employed, and then adding known weights of other reagents to samples of the same solution of peroxide and again determining the iodine value of the several solutions after definite intervals of time. From the first set of experiments it was seen that whereas the original solution slowly lost its strength until after 176 days the loss was equivalent to 20 per cent., the addition of ferrous nitrate and sulphate, and zinc sulphate accelerated this decomposition, so that the solutions after the same lapse of time showed 95–97 per cent. of loss, and the addition of the chlorides and nitrates of the alkaline metals and earths had a slight retarding action, the minimum loss being 14 per cent. when a 5 per cent. solution of strontium nitrate was employed.

In a fresh series of experiments the one cent. of substance was added in each case, and organic substances were employed, and it was found that under these conditions alcohol and ether had the greatest retarding action, while phenylacetic acid, sulphophenic acid, chloral, phenol, β-naphthol, and thymol had also considerable retarding power. The last three of these reagents had, however, undergone some change, as the solution, at the end of the experiments, was discoloured brown. These last experiments were also performed with neutral solutions of the hydrogen peroxide, as by a further set of results with a slightly acid solution different percentages of loss were obtained.

As a result of this investigation the author has patented the use of certain chemicals for retarding the decomposition of solutions of hydrogen peroxide, and the Sanitas Company are now selling a patent preserved peroxide of hydrogen of ten volumes strength for bleaching wool, silk, ostrich feathers, hair, ivory, bone, sponges, and other materials. It is also suggested for use in breweries as a substitute for sulphurous acid and bisulphite of lime, and as an antiseptic and general sanitary reagent. In the course of the paper the author stated the action of silver oxide or peroxide, as producing ozone, according to the equation

$$3H_2O_2 + 3Ag_2O = 3H_2O_2 + Ag_4O_4 + Ag_2 + O_2,$$

and, in reply to Professor Clowes, stated that such reaction had been demonstrated by Berthelot. The author also was of opinion that in hydrogen peroxide the second atom of oxygen possessed an unusual valency, and, in reply to Dr. Rideal, stated that he had no statistics to show the economy of oxygen in this form over other bleaching compounds.

Mr. Joseph W. Lovibond then gave a demonstration of the value of his patent tintometer for measuring and recording the colours of bodies. This instrument, of which several forms were exhibited, consists of two tubes, side by side, both open at one end, one giving a view of the object to be measured and the other a view of certain coloured glasses which are introduced to match the colour of the object. At the other end of the instrument is a single eye-piece, commanding a clear vision at the same time of the object on one side, and measuring glasses on the other, under exactly similar conditions, and uninfluenced by the nature and colour of the surroundings. The coloured glasses are made on a series of standard scales in three colours, from cobalt, gold, and silver glass, and from these three primary standards by combination all other colours can be obtained. By its use a permanent record of the colour of a substance can be obtained and recorded in numbers, and can be reproduced at any future time. The author is of opinion that the coloured glasses employed, which have been made with great care, will be permanent and capable of being reproduced without alteration of the numerical scale now adopted, and maintains that the unit can always be checked by means of substances of permanent colour—*e.g.*, copper nitrate, potassium bichromate. The colours are measured on a black ground of pure plaster of Paris or on Chance's opal glass, and any ordinary daylight is suitable, except direct sunlight and twilight, for illuminating the glasses and object. The instrument has already been used with success for many scientific and trade purposes, such as the determination of the amount of carbon in steel, of ammonia by the Nessler test, and for recording the colour of fabrics, yarns, sugars, petroleum, flour, malt, paints, &c. Dr. Munro has also used the instrument for recording the colours of different waters, and from an examination of the varying colour of a sulphur spa was able to show that the colour variation coincided approximately with the amount of sulphuretted hydrogen present in the water, and from noting the colours of adjacent waters formed an opinion as to which of these several waters percolated into the sulphur spring.

Notes.

SAFETY APPARATUS FOR TRANSFORMERS.

In our note under this heading last week we described Major Cardew's apparatus as if it were arranged so as to short circuit the primary or secondary and melt the fuses in case of its acting. Though this method of connection has been described, in practice it is now arranged merely to earth the secondary when necessary. Its efficient action, therefore, does not depend on the primary fuses going. This difference of connection does not affect our other remarks.

VENTILATING ELECTRIC SUBWAYS.

Mr. Isaac La Rue Johnson proposes to ventilate subways by making one of the lamp posts, every here and there, of special form, and driving a screw fan in it by a little electromotor.

"ELECTRICAL INDUSTRIES."

Under this title a new paper was started in Chicago on the 1st of December last. It commences with well-written articles, good illustrations, and a fair instalment of advertisements. Like most American papers, it is well printed, and we have little doubt that our new contemporary will have the long life we heartily wish it.

INSULATING VARNISH.

We have tested Messrs. Griffiths' so-called anti-sulphuric black varnish. It dries quickly, and gives a very good surface. We have baked it in a self-regulating oven, and find it stands 120° C. for long periods. Kept at 150° C. for twenty-four hours it gets brittle.

FREE SPACE IN THE EDINBURGH EXHIBITION.

The Council have resolved to charge no rent for space unless the working of the Exhibition results in a deficiency. If it does, it seems only fair that the rent then charged should fall on the shopkeeping exhibitors, and not on those who show new and attractive exhibits. We wonder whether the London Chamber of Commerce will protest that the electrical exhibitors should be rent free in any case.

MINERALS IN COLORADO.

Some official figures have been issued dealing with the mineral resources of Colorado, from which it appears that coal lies under 36,000 square miles of territory, and has scarcely been touched. Both soft and hard coal are found, and in addition ironstone of various qualities exists in large quantities. Copper and lead are abundant, gold and silver also are obtainable, and petroleum has been recently discovered in several districts. It is only within the last few years that the State has directed attention to the large mineral wealth which it possesses, but there is little doubt that it will soon be developed.

A NEW THEORY OF DYNAMO DESIGN.

Mr. Nikola Tesla, who is perfectly indefatigable in inventing queer alternating motors, has started the theory that, as the output of a machine varies as the product of the energies spent in the armature and fields, these losses should be equal to give the largest output with a given loss. There seems to be some obscurity about this reasoning. The output of a machine does not vary as the product of the ampere and field ampere turns alone, but also depends on the design of the armature, field magnets and pole pieces, and air gap. Moreover, the power lost in the armature and field magnets depends on the lengths of the windings and on the current densities.

IRONMONGERS' EXHIBITION.

Mr. Harry Etherington, of 43, New Oxford Street, who rather more than a year ago arranged an Ironmongers' Exhibition at the Agricultural Hall, Islington, intends to repeat the venture in March with a more extensive scope, indicated in its new title—viz., "An International Exhibition of Machinery, Manufactures, Appliances, and Inventions incidental to Engineers, Electricians, Builders, and Ironmongers." On this occasion the building will be lighted by electricity, and it might be incidentally suggested that a permanent electric light plant would be an advantage there, especially when the Smithfield Show is being held. Applications for space are to be made before the 24th of February.

CONTRACTS FOR LOCOMOTIVE COAL IN 1889.

There is nobody that is likely to suffer more from the increased price of coal than the railway companies, some of which, at the lower rates of the last few years, have paid from £16,000 to £22,000 a month for their locomotive fuel. Up to about the end of 1888 and during the first half of the year 1889 the average price paid for coal by the railway companies was about 6s. per ton, but owing to the increased demand for all kinds of coal which began in the last quarter of the year named, and the consequent advance in the wages paid to miners, the colliery owners gave timely notice that the new contracts for coal and coke would only be taken at rates considerably above those then running. It appears that when coal was at the ordinary rate alluded to the London and North-Western expended about £22,000 a month for locomotive or steam coal, the Midland £18,000, the Great Western £16,000, and the North-Eastern £17,000, the latter consuming about 50,000 tons of coal monthly. One of the first contracts that were required at the commencement of last year was that of the Great Northern, who had been paying 6s. a ton, but the old contractor required an advance of about 40 per cent., but ultimately agreed to a short time contract at 8s. per ton. At the end of June the contracts of several railway companies expired, and they sought for renewals, but these were only offered at not less than 8s. 6d. per ton, or an advance of about 42 per cent., and these the companies were obliged to accept, with the exception of the Great Eastern, the directors of which were able to obtain a small contract at a rather less price, but were obliged to take a rather inferior quality of coal. The last proposal for tenders was made at the beginning of December, on the part of the North-Eastern, for supplies for the new year, commencing with January.

EXHIBITION OF BRASS WORK AND ARMOURY.

The Company of Armourers and Brasiers intend to hold in May next an Exhibition of modern armour and blades, and of works in brass, bronze copper, and other metals combined with brass. The exhibits will comprise helmets, breastplates, and blades; church furniture, such as altar crosses, screens and gates, ornamental hinges; stove decorative mounts, fire-dogs, fenders; chandeliers, gaseliers, electroliers; cire perdue castings, &c. For very large work, such as park gates, chancel gates, &c., only designs can be accepted. Numerous prizes will be given to craftsmen, and certificates to manufacturers. Specimens, models, or designs of improved tools for use in the manufacture of the foregoing articles will have a section reserved for them. Applications for space should be made to Mr. Marshall Pontifex, Armourers' Hall, 81, Coleman Street, E.C.

ORIENTAL ENAMEL ON TILES.

J. Boeck has recently communicated to the *Journal fur Practische Chemie* the results of his examination of the chemical composition of certain ancient Turkish blue enamels, and suggests that this enamel can be imitated in the following way:—A mixture of sand (53·53 p.c.), copper oxide (3·51 p.c.), litharge (18·3 p.c.), chalk (5·4 p.c.), tin oxide (6·9 p.c.), potassium carbonate (5·2 p.c.), and sodium carbonate (12·5 p.c.) is heated in a Hessian crucible until the mass begins to soften and form a glass without dissolving the oxide of tin. In this operation air must have free access to the mixture, so that the lead and copper oxide are not reduced. The mixture is next poured into water, powdered, and moistened with water, and is then ready for burning on to the clay. The earthenware from which the enamel was taken was made from a marly clay, and was very porous, but had been burnt to a moderate hardness.

JAPANESE LACQUER.

Japanese lacquer is an exudation from cuts in the bark of the young trees of *Rhus vernicifera*. The sap is first greyish white and thick, but rapidly darkens through yellow to black. An inferior lacquer is obtained by soaking the branches in water, and requires straining before being fit for use. Certain lacquers have a small proportion of drying oil (perilla oil) added to them. The principal constituent is urushic acid, and this acid is always associated with an albuminoid substance, a gum, and a poisonous volatile acid. The hardening of lacquer is due to the oxidation of urushic acid, and the finest black is obtained by adding iron or an iron salt to the liquid, which forms a black iron salt with this acid. A coniferous wood is usually used for lacquer work, and all joints and holes are first filled with a putty-like material made from inferior lacquer and rice flour.

FREEDOM OF CONTRACT.

Although action has been taken in the past by the Liberty and Property Defence League in connection with legislation affecting the relations between capital and labour, that body has hitherto not concerned itself with labour difficulties. In the annual report, which has just been published, they, however, express the opinion that in some of the strikes which have occurred within the past six months the men have shown an intention of claiming more than the right of combination ensured to them by the Trades Union Act of 1871. They state that "the intimidation and picketing directed against non-unionists, willing to sell their labour to the employers in the open market at the market price, is an attempt by the trade unionists on strike to add to their own share of liberty by curtailing the liberty of their fellow workmen."

THE "POST OFFICE GUIDE."

In a disastrous fire which occurred at the business premises of the printer of the "Post Office Guide" on December 25th, the whole of the type set up for the publication of the January edition was destroyed, as well as many thousand copies of the Guide which were already completed for issue. As it is found that it will be impossible to reset the type and to issue a new edition of the Guide for a considerable time, the Postmaster-General, while deeply regretting the inconvenience which will be caused to the public, has decided to suspend the January edition altogether, and to issue an edition on March 1, to be substituted for the edition which in ordinary course would have been issued on April 1 next. In order that the public may suffer the least possible inconvenience from this disaster, a short statement of the principal alterations which would have appeared in the January edition has been printed on a separate sheet, copies of which are obtainable at any post-office. The "Post Office Handbook," in which these alterations are to a great extent embodied, has been issued in due course, and copies may be obtained at any post-office at the price of one penny.

A SUBSTITUTE FOR OAK BARK IN TANNING.

In a recent United States consular report Mr. Merry describes "a vegetable product which will become a ready and perfect substitute for the rapidly vanishing oak of our own country." This is the Australian wattle, which belongs to the widespread family of acacias, and which is cultivated extensively in New South Wales and Victoria, where it lends a charm to the scenery both by its fragrant blossoms and its exquisite foliage. The two varieties most cultivated are the black and the broad-leaved wattle, and both can be grown in an exceedingly dry climate and a poor soil. The black wattle produces a large amount of tannic acid. Its value for tanning will be understood when it is mentioned that hides can be readily tanned in a bath of liquor made from black wattle in 47 days, whereas in liquor made from the bark of the Santa Cruz oak, the best known in the Pacific States, the time required is 75 to 80 days. The black wattle contains 30 to 32 per cent. of tannic acid, the broad-leaved wattle 26 to 28, Santa Cruz oak 16 to 18, and other kinds of oak less still. Although the broad-leaved wattle has less acid, it has certain advantages over the black variety. It is a larger and handsomer tree, and can withstand a greater amount of frost.

OXALATE OF MANGANESE AS A DRYER.

M. John Castelar, in the *Moniteur des Produits Chimiques*, has drawn attention to the valuable properties possessed by manganese oxalate as a dryer. This salt has hitherto not had any important industrial uses; but as it can be readily prepared in a state of purity from the native carbonate by the action of oxalic acid, the author is of opinion that it will be found of use for this purpose. If prepared from carbonate free from iron and lime, it can be obtained as a fine crystalline white powder, and 2–5 per cent. is sufficient to being about the change. The oxalate is resolved by heat into manganese oxide, carbonic acid, and carbon monoxide, and in the presence of fatty acids the manganese oxide formed combines with them, the decomposition taking place at about 130 deg. The operation is easily carried out by mixing in a mortar the oxalate with two or three times its weight of oil, and then adding the mixture to the main portion of the oil. The heat should be applied gradually, and the decomposition is known to be complete when there is no further evolution of gas. The boiled oil, under this treatment, preserves its limpidity, and also remains colourless. Manganese oxalate has the advantage over oxide of lead, which is commonly employed for this purpose, in causing the oil to remain transparent when exposed to sulphur vapours. Manganese acetate has also been used, but it likewise causes a darkening in the colour of the oil, and the nitrate is dangerous, owing to the possible action of nitric acid on the fats present in the oil. Manganese borate appears to be next in value to the oxalate as an oil dryer.

20746. Baier, X. ..... Finishing planes for tyres.
20747. Vavasseur, J. ..... Mounting for gun.
20748. Jenks, W. H. ..... Engine governors.
20749. Wolseley, F. Y..... Apparatus for imparting motion to machinery.
20753. Bénier, L..... Steam engines.
20755. Gehre, M. ..... Determining amount of water contained in steam.
20756. Hope, G. F. W. ..... Sand separators.

ELECTRICITY.

23rd December, 1889.

20627. Mordey, W. M. ..... Electric distribution.
20645. Dearlove, J. A. L..... Coating telegraph cables.
20646. Cassagnes, G. A..... Printing telegraphic apparatus.
20652. Edmundson & Clarke Incandescence electric lamps.
20653. Foster & Griffiths ... Telegraphic insulators.
20660. Winckler, J. O. ..... Electric signalling apparatus.

24th December, 1889.

20717. Prentiss, H. S..... Electric cams.
20734. Haddan, R. ..... Magneto-electric machines (*Gillette*).
20743. Sechehaye, E. ..... Projectors of electric light.
20751. Marx, F. ..... Accumulators.
20752. Marx, F. ..... Electrodes.
20764. Thompson, W. P. ..... Electric machines (*Westinghouse Electric Company*).

CHEMISTRY.

23rd December, 1889.

20665. Baswitz, C. ..... Treatment of textiles by ammoniacal oxide of copper.
20668. Johnson, J. Y..... Colouring matters (*Badische Anilin und Soda Fabrik*).
20678. Imray, O. ..... Rosaniline dyes (*Farbwerke vormals Meister, Lucius and Brüning*).

24th December, 1889.

20722. Fell, J. C..... Ammonia from atmospheric nitrogen (*American Ammonia Manufacturing Company*).

MISCELLANEOUS.

23rd December, 1889.

20596. Alderton, G. H. ..... Fog signals.
20599. Waller, G. ..... Decorative earthenware tiles.
20610. Illingworth, C. R. ... Shoes for horses.
20611. Foden, E. R..... Apparatus for signalling.
20619. Sowerby, J. G. ..... Cutting glassware.
20634. Snoeck, A. ..... Shuttles.
20679. Myall, A. ..... Smokeless and gasless fuel (*Lancaster*).

24th December, 1889.

20693. Gillett, S. W..... Shuttles (*Kelly & Kelly*).
20750. Bing, N. C. ..... Distributing oil on water.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Gas Engines.—*J. McClure, Caldwell Paton, Nottingham.*—The invention consists of an appliance for starting gas and similar engines. The improvement consists in the employment of a self-acting centrifugal friction clutch, which releases the driving pulley upon the crank shaft when starting, but after the engine has attained sufficient speed automatically couples it to the shaft. The clutch is formed of friction blocks fixed to the crank shaft by levers. When the engine is moved slowly the blocks are held by springs close to the shaft, but as the speed increases the centrifugal force presses the blocks out and against the rim of the driving pulley. Claim: The application upon the crank shaft of a gas or similar engine of a centrifugal clutch so arranged that it disconnects the crank shaft and driving pulley when the engine is stopped, and automatically connects them when the engine is nearing its normal rate of speed, and automatically disconnects them again when the engine slows speed. —No. 441. January 10th, 1889. 8*d.*

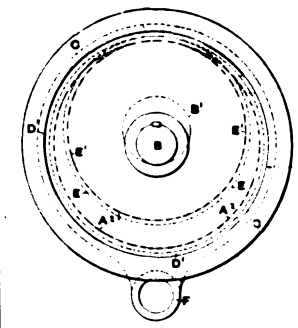
Lathes for Stone.—*T. Turner, Ketton, Rutland.*—This invention relates to lathes for turning stone, and its object is to improve the arrangement of the tool rests and apparatus for gauging articles in process of turning. The inventor arranges a shaft or bar above, and parallel to, the lathe centres. It may be carried in bearings formed in vertical supports, the lower ends of which may be secured to the headstocks. On this shaft a number of gauges are arranged; they are carried on or between sliding bosses, by means of which the gauges are adjusted and secured in their desired positions on the shaft. The gauges rotate freely on or between the bosses secured on the shaft, and each one is provided with a steel pointer sliding freely in the gauge, the point of which may be adjusted to any suitable distance from the centre of the shaft or lathe, and secured by means of a set screw. The points of the gauges are set so as to pass over the article in the process of turning at that part where they are fixed to gauge, as soon as it is reduced to the desired diameter, when they pass to the back out of the way, and may be turned over the top of the shaft and brought in front when commencing a fresh article. The points of the gauges may be held in contact with the article in the lathe centres by springs, or they may be formed with a weight, or be provided with a vessel in which weights may be placed as required. By this arrangement, when turning fancy articles, such as balusters, a gauge may be arranged for each separate part of the baluster. The gauges are held in contact with the baluster, and indicate immediately when each part is reduced to the requisite diameter. The inventor arranges on the tool rest two or more checks or plates, which slide laterally on the rest, and which may be adjusted and secured by set screws to different parts of the work, and act as guides for the tool. Centres may be formed for turning such articles as stone balusters by forming a hole at each end and inserting a metal plug or a metal plate having one or more projections fitting into corresponding holes in the ends of the balusters, centres being formed in the plug or plate, which are secured by any suitable composition to the baluster. The stone balusters are driven by means of an adjustable clamp fitting on and bolted to the square end, which engages with a pin in the driving plate of the lathe. There are two claims.—No. 685. January 14th, 1889. 6*d.*

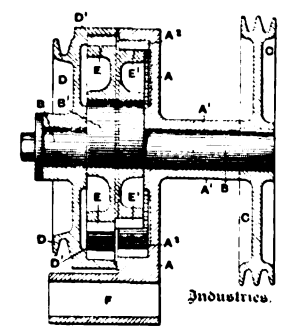
Brake for Hoisting Apparatus.—*W. M. Simons & G. Sadler, Nottingham.*—The apparatus here described is operated by a rope coiled round a flanged pulley, which is attached to the axle of the hoisting drum. As the load is raised by pulling the rope, the rope unwinds from the pulley and *vice versâ*. The rope, as it leaves the flanged pulley, passes over a second pulley, supported upon one arm of a lever, the other arm of the lever being made to raise or lower a wedge between the flanged pulley and the frame of the apparatus. When the rope is pulled to raise the load, the force exerted upon it causes it to depress that end of the lever supporting the pulley, and the other end is therefore raised, and in its turn raises the wedge behind the flanged pulley and so releases the pulley. If the hoisting rope be now let go the lever assumes its former position, and the wedge drops behind the flange pulley and holds the drum fast. One claim is made for the construction of an automatic brake as described.—No. 1726. January 31st, 1889. 6*d.*

Hydraulic Hoists.—*R. Wright, Newcastle-upon-Tyne.*—In this apparatus the lift cylinder is connected to another cylinder of the same capacity in which a plunger works. This plunger is forced in by the combined efforts of three other hydraulic cylinders. The ram of one of these cylinders acts upon the plunger vertically and in a line with its axis. This ram is of the dimensions required for lifting the live load. The cradle and the lift ram are balanced by the two other cylinders, and in such a manner as to compensate the varying immersion of the lift ram. The balancing cylinders are constantly open to the pressure main; they are carried by trunnions arranged so that their rams act obliquely on the plunger. The obliquity increases as the plunger passes from one end of its course to the other. The variation of the obliquity of action of the compensating rams is made to counter-balance the effects of the varying immersion of the lift ram. Claims: (1) Compensating the varying immersion of the lift ram and plunger or plungers by the varying obliquity of cylinders forming a portion of the hydraulic gear; (2) the arrangement of direct acting hydraulic hoists or lifts as described.—No. 2075. February 5th, 1889.

Carding Engines.—*J. McQueen, Manchester.*—The invention relates to the means employed to obtain a reduced speed of revolution of the main cylinder and doffer of a carding engine during the operation of grinding the wire cards on such cylinders. In the improved apparatus is employed a differential motion to effect the required reduction of speed. In the motion an external spur wheel is carried around in rolling contact with an internal spur wheel and is attached to a second external spur wheel which gears with a second internal spur wheel. The two internal spur wheels differ in the number of their teeth, and as the first one is kept from revolving, the second one is caused to revolve, but at a speed which is less than that of the part which carries around the first external spur wheel. Fig. 1 is a front view of the apparatus, Fig. 2 a side view in section, and Fig. 3 shows the apparatus mounted upon the carding engine. Through the

FIG. 1.





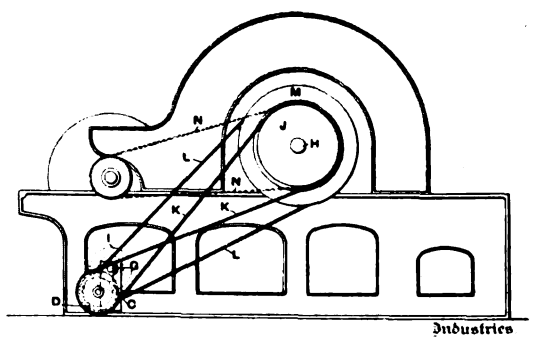


FIG. 2.

boss A^1 of a supporting frame A passes the shaft B with an eccentric B^1 fixed to it. Upon one end of the shaft is fixed the V pulley C, and upon the eccentric is supported a double-toothed gear wheel, which is free to revolve upon the eccentric, and has one part E^1 smaller in diameter than the other part E. The part E^1 of the double-toothed wheel gears in the supporting frame A, whilst the part E gears in the internally geared surface D^1 of the V pulley D, which is also supported upon the shaft B. It may now be seen that by revolving the pulley C the eccentric B^1 will revolve and cause the part E^1 to roll in gear with part A^2, and the part E with the geared surface D^2. The surface A^2 remaining stationary and part E being larger than part E^1, will cause the pulley D to revolve at a slow speed in the same direction as the shaft. Fig. 3 shows the apparatus mounted upon a stud G, which usually carries the intermediate band pulleys as

FIG. 3.

indicated by the dotted line I. The pulley C of the slow motion apparatus is driven by a band K passing over the pulley J upon the main cylinder shaft H, and the slow motion is communicated to the main cylinder by the band L passing around the pulley D. Claims: (1) The apparatus constructed as described; (2) a slow motion apparatus for carding engines provided with the differential gearing A^2 E^1 C and D^1; (3) a slow motion apparatus for carding engines adapted to be applied as an intermediary between the ordinary driving apparatus and the main cylinder or doffer, such apparatus being provided with a pair of differential spur wheels eccentrically mounted upon a central shaft and carried around so that one wheel is in rolling gear with a fixed internal wheel and the other spur wheel is in gear with a second internal wheel, which imparts the motion reduced in speed to the main cylinder or doffer; (4) the means for obtaining slow rotation of carding engine cylinders.—No. 817. January 16th, 1889. 8*d.*

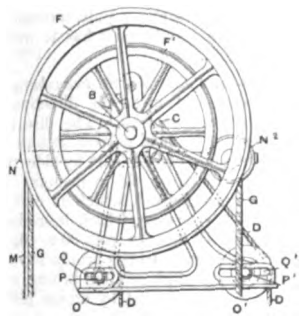
Safety Valves for Hydraulic Cranes, &c.—*T. Harris, Newport.*—The valve is contained in a chamber fixed to and communicating with the pipe through which the water flows to and from the ram cylinder, and is situated between the ram cylinder and the regulating valves. To the valve proper is attached a piston working up and down within a cylinder. The piston, and thus the valve, are pressed down to close the valve by a suitable spring acting upon the top of the piston. The under side of the piston and cylinder are in communication with the hydraulic main, the pressure of water from the main being sufficient to overcome the resistance of the spring and keep the valve open. Should the pressure in the main become reduced by fracture or other means, the pressure under the piston being then

Digitized by Google

reduced, the spring forces down the valve, and prevents the escape of water from the ram cylinder. Claim: In a hydraulic crane, hoist, lift, and the like, the use, between the working valves and the ram, of a valve, the spindle of which is fitted with a piston surrounded by a spring or its equivalent, and working in a chamber communicating at the bottom by an orifice or channel with the water supply by which the ram is actuated.—No. 1875. February 2nd, 1889. 6*d*.

LIFT APPARATUS.—*J. Haskins, London.*—An apparatus is here described for raising loads, the load raised being caught and retained at any point where the haulage ceases. Fig. 1 is a side elevation of the apparatus, Fig. 2 is an end elevation of the apparatus, Fig. 3 is a side elevation with part broken away, and Fig. 4 is an end elevation partly in section. Referring to the figures, C is the pulley for raising the load by the rope D, F the pulley for hauling up the load by the rope G. The two pulleys F and C are connected to the shaft B, whose ends are supported in the bearings E E^1, and its centre supported by hinged collars I J suspended from a shaft K. The bearing E^1 of the spindle B is free to rise and fall in guides in the framing, but the height to which it can rise is adjusted by a screw A^2. The bearing E also works in a guide and rests upon the pin E^2 of a weighted lever

FIG. 1.



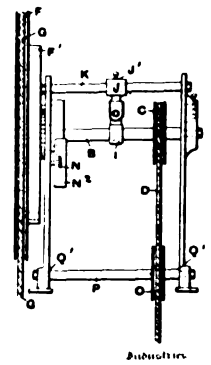


FIG. 2.

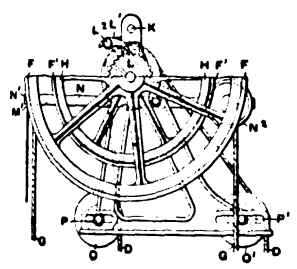
N. The central bearing collars I J are made adjustable upon the two shafts. Upon one side of the wheel F is a flange F^1, which constitutes with the wheel H a friction break. The wheel H is mounted upon a hollow boss, and is prevented turning in a direction opposite to the hauling motion by a ratchet wheel and pawl L^1. The action of the apparatus is as follows: When the weight becomes suspended upon the pulley C, the end B^2 of the shaft becomes depressed, and the shaft levering upon the collars I J the opposite end B^1 is raised, and the flange F^1 coming into contact with the wheel H forms the break, and holds the load in that position. If hauling is now commenced the end B^1 becomes depressed and flange F^1 freed from contact with the break wheel H, as the weight of the load is made to balance the pull upon the hauling cord by adjusting the collars I J. If a rapid descent of the load is required the bearing E is released from the

FIG. 3.



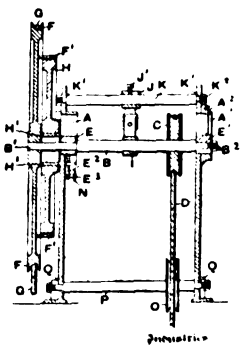


FIG. 4.

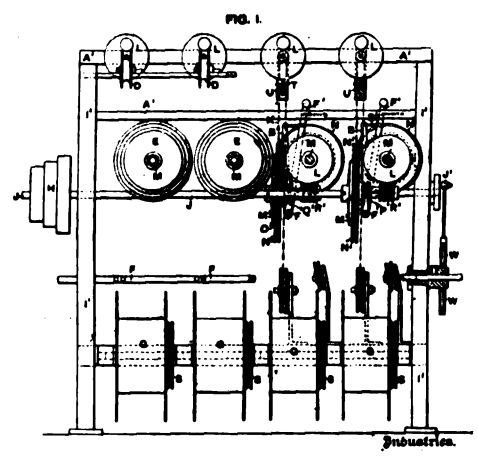
action of the weighted lever by the cord M^1. Claims: (1) In a lift apparatus the combination with the break wheel of a haulage wheel having its axis suspended on a rocking centre, arranged so as to be adjustable as to the leverage exercised on the load wheel; (2) in a lift apparatus the arrangement or combination and use of adjustable sliding suspending bearings linked or hinged together, forming an adjustable point of suspension for an axis carrying the haulage wheel or wheels, and the load supporting wheel or wheels, sliding vertical bearings therefor, a break wheel to co-operate with said haulage wheel, a lever for disconnecting the same for lowering; (3) the combination or arrangement and use of parts of lift apparatus as described.—No. 1034. January 19th, 1889. 8*d*.

SAFETY APPLIANCES FOR HOISTS.—*R. Middleton, Leeds.*—This invention consists of a mode of actuating safety catches. An extra rope is attached to the main balance weights, and, in case the main balance weights give way, it produces a pull such as throws the safety clutches into action. This rope also causes an arm on a shaft, round which it is led on a rope-pulley, to revolve so that when any dangerous speed is reached a portion of the revolving arm flies out and releases a catch. This catch either brings the gripping devices into action or sets a brake to work on the main shaft. The object of this invention is to simplify the mechanism and increase the efficiency of safety catches; and to add to the usefulness of the gripping wedges referred to in the complete Specification No. 15292 of 1887. The gripping wedges are fixed to the cages, and their actuating levers are arranged on the cage roof. In connection with these latter is the safety-rope, so attached that when firmly pulled the wedges are put into action. The "safety-rope" is led upwards to the overhead beams, and then downwards, after being taken over one or more pulleys. Attached to its end are by preference one or more smaller counter-weights, whose duty it is to keep the rope tight and consequently in good contact with the last-mentioned pulleys. On the shaft of one of these pulleys is fixed a wheel capable of retaining any catch that may be dropped into it, and an arm or lever on which a weight is arranged to slide. This weight is held in mid position on the arm by one or more springs. The arm and its weight necessarily revolve whenever the cage moves, by reason of the "safety-rope" being led over it. At ordinary speeds the weight on the arm occupies a position which clears an adjacent tappet, but at a given extra speed it flies out far enough to strike this tappet. The consequent locking of the pulley produces an additional pull at that end of the "safety-rope" which is attached to the levers, and the gripping wedges are thus pulled into action. There are five claims.—No. 2109. February 6th, 1889. 8*d*.

ARMOUR PLATING.—*J. Ward, Coatbridge, Glasgow.*—This invention has reference to a new construction of compound armour plates, and is also applicable to compound ship and boiler plates and sheets. The novelty of the invention consists in the use of layers of puddled bar iron in combination with steel or iron. According to one arrangement, a compound steel and iron armour plate is produced, by taking a hard steel face block or slab, and an ordinary malleable iron back plate or slab, both previously roughly cogged or hammered to the desired thickness, and uniting them together by placing a thin layer of puddled bar iron between the inner surfaces of these slabs, and then heating the combined block when placed in a furnace. When sufficiently heated they are removed from the furnace and rolled through the rolls of a mill, and thus reduced to the desired thickness of plate required. Under another arrangement, a compound steel armour plate is produced by taking a face block or slab of hard steel, and a back slab or block of soft steel low in carbon, all previously roughly cogged or hammered, and uniting them together by placing a thin layer or layers of puddled bar iron between the inner surfaces of these slabs or blocks, and then heating the combined slabs thus placed together in a furnace, and when sufficiently heated passing the combined slab or block thus formed through the rolls of a rolling mill to reduce the compound plate to the thickness desired. Other methods are also described in the specification. There are four claims.—No. 1,987. February 4th, 1889. 8*d*.



STEERING VESSELS.—*B. J. B. Mills, London.* (*J. L. Horing, Jersey City, U.S.A.*)—This invention relates to that kind of steering apparatus for vessels in which the rudder of the vessel is moved by the admission to a cylinder of a fluid such as air, steam, or water, under pressure. One object of the inventor is to provide a simple arrangement by means of which the valve will be brought back to its position of closing the cylinder ports by the movement of the rudder. A further object is to so combine the power-steering apparatus with the hand-steering apparatus that if at any time the power apparatus becomes inoperative, the hand apparatus may be readily used instead. The method of carrying out these improvements will be understood from the claims: (1) The apparatus for steering vessels having in combination with the rudder the fluid pressure motor containing a piston connected with the rudder, the hand-steering wheel also connected with the rudder, the power-steering wheel, a bevel gear on the shaft of said hand-steering wheel, a bevel gear on the shaft of said power-steering wheel, a bevel gear engaging with both said gears, a gear wheel carrying said last-mentioned bevel gear, another gear wheel with which said carrying wheel engages, and connections from the shaft of said last-mentioned gear wheel to the valve, which controls the admission and outlet of fluid for the motor; (2) the combination of the rudder, the fluid pressure motor having a piston connected with the rudder, the hand-steering apparatus and the relief cocks and inlet valve for the motor connected with a handle at the place where the steering is performed so as to enable the hand-steering apparatus to be used; (3) the use in steering apparatus, in combination with a rudder, of a motor consisting of a tight case which is fan-shaped or approximately so, and a movable piston within such case, which is pivoted at the apex or small end of the case so as to be moved on its pivot in a curved line by the pressure in said case, said piston being connected with the rudder head.—No. 1887. February 2nd, 1889. 8*d*.

APPARATUS FOR WORKING PUNKAHS.—*T. T. Watson, Jubalpur, India.*—On a framing is mounted, some height from the ground, a horizontal cylinder fitted with a piston and provided with a slide valve and ports for admission and emission of the working fluid. The piston rod crosshead is connected by side links to a lever, which is pivoted at the lower part of the frame, and extends upwards, having attached to its top the rope leading to a punkah. The piston rod crosshead acts on adjustable tappets on the rod of the slide valve, so as to shift the valve at each end of the stroke. The working fluid acts on the one end of the cylinder, the bottom being opened when fluid under pressure is used, but when the apparatus is worked by vacuum the bottom is closed and connected to a vacuum chamber. The fluid in propelling the piston back thereby pulls the lever and the punkah attached to it, and the crosshead on meeting the hinder tappet shifts the slide valve so as to cut off supply of fluid and open discharge. The punkah and lever then swing back, drawing the piston until its crosshead meets the front tappet and shifts the valve, so that the discharge is closed and fluid again acts upon the piston. Claim: Apparatus for working punkahs, consisting of a vertical lever connected to a punkah or set of punkahs, and to the rod of a piston moved by fluid pressure in a cylinder, the ingress and egress of the working fluid being governed by a slide valve moved by adjustable tappets acted on by the piston rod as described.—No. 18087. December 11th, 1888. 6*d*.

REFRIGERATING CHAMBERS.—*R. C. A. Banfield, London.*—The cooling of air is effected by contact with extended surfaces which are cooled by refrigerated brine or other uncongealable liquid. The cold air is by pumping or otherwise caused to circulate from and to the refrigerating apparatus and through a set of troughs. In the troughs are mounted several transverse shafts, which are caused to revolve. On each shaft are fixed a number of parallel discs partly immersed in liquid. The troughs are situated in a passage through which the air passes in a current parallel to the revolving discs. Thus, as the discs revolve in the refrigerated liquid, the air passing in numerous streams through the spaces between the discs becomes cooled, depositing excess of moisture and impure gases or other matters that may be suspended in it, by contact with the cold moist surfaces of the discs. Claims: (1) The herein-described method of cooling air by causing it to pass in numerous thin streams between discs revolving partly immersed in cold liquid; (2) for the purpose of cooling air in the manner above referred to, apparatus consisting of a number of parallel discs mounted in the air channel and caused to revolve partly immersed in cold liquid, circulating from and to refrigerating apparatus.—No. 11849. July 25th, 1889. 6*d*.

COVERING WIRE WITH COTTON, &c.—*T. C. Barraclough, Manchester.*—This machine is designed to give off a larger percentage of work than is usual in present machines. The machine is constructed of a number of similar sections, and each individual section made to stop instantly and automatically whenever a spool or bobbin becomes empty. Fig. 1 is a front elevation, and Fig. 2 an end elevation of the machine; parts in each being shown in section. A driving bar J is mounted upon the framing I^1 of the machine. In each similar division of the machine a friction disc M^1 is fixed to the shaft J. The friction disc drives the V pulley N^1 which is connected to the worm R^1. The worm R^1 is geared to a wheel L upon the shaft M, which carries the drawing rolls E and a V pulley N for driving the receiving reels G. The reels G are driven by an endless belt passing round the pulleys N, P, Q, and S. A is the spool for the bare wire. L^1 are the spinning discs

FIG. 1.

which are driven by an endless belt passing over the pulleys B, C, R, and N^1. A clutch arrangement Q^1 F^1 is provided for putting the pulley N^1 in contact with the friction disc. The action of the machine is as follows:—The two spools containing the desired covering yarns or strands are placed upon the pins of the spinning discs L. The bare wire upon the spool A is drawn through the two hollow spindles of the spinning discs, over the guide pulley D, and once or more round the drawing pulley E, and then fixed to the reel G. The ends of the covering yarns or strands are drawn through eyes formed in the small hinged levers U and through the guiding levers T and fixed to the wire. The machine thus prepared is set in motion, and as the drawing pulley E draws the wire off the spool A the two spinning discs rotate in opposite directions and wind the fibrous material round the wire in a spiral direction. When a covering yarn or a strand breaks, or a spool

FIG. 2

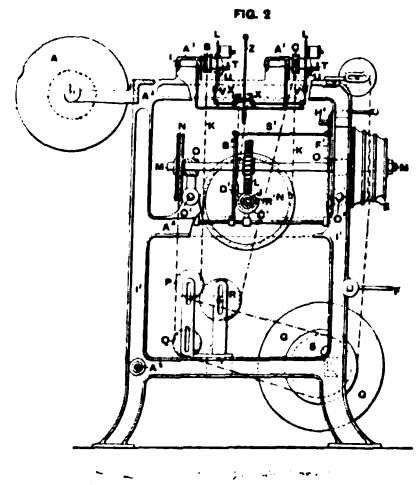


FIG. 3

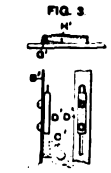

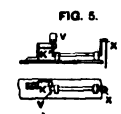

FIG. 4.

FIG. 5.

becomes empty, the hinged lever U ceases to be held in position by the tension of the threads. The centrifugal force of the spinning disc therefore acts upon it and causes it to assume a radial position and strike the lever V. The lever V when struck falls and allows the weight D^1, attached to the other end of the lever by a string, to fall and put the striking gear out of action. A crank disc is mounted upon the end of the shaft J, to work by a ratchet wheel W the guides F of the receiving reels G. Claim: The improved construction and arrangement of wire covering or lapping machine provided with automatic disconnecting gear in which the stoppage of each covering and winding section of the machine is ensured whenever a breakage occurs in the winding threads or strands or a spool becomes empty by a lever mounted upon the spinning discs and held by the tension of the threads, and which tension being removed causes the release of a friction coupling.—No. 15340. September 30th, 1889. 8*d*.

HYDRAULIC GAS MAINS.—*D. Irving, Bristol.*—This hydraulic gas main is constructed in such a manner as to allow of the seal of the dip pipes being adjusted with facility and accuracy, and at the same time afford ready means for flushing the main to remove any thick tar that may accumulate. The liquid for sealing the dip pipe is kept within the main by a sluice gate form of valve. The liquid is kept at a certain height by raising or lowering the gate, the superfluous liquid flowing over the edge of the gate. When it is required to discharge the thick tar accumulated in the main the gate is raised to its full height, and the tar allowed to flow out beneath into a pipe below the gas outlet pipe provided for carrying off the liquid. The gate is raised and lowered by a worm upon a shaft gearing into a rack upon the back of the gate. The shaft is operated from above by a wrench, and is provided

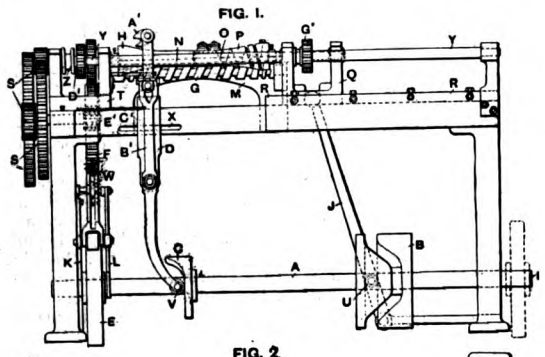
Digitized by Google

with a pointer to indicate the position of the gate, and a locking arrangement to prevent the gate being raised too high in error, and so allow the liquid to escape, breaking the seal. Two claims are made for the apparatus as described.—No. 17697. November 6th, 1889. 6*d*.

Tramway Points.—*T. Tweddell, Hartlepool.*—The invention is applicable to tramways in which the flange of the wheel runs in a sunk groove, and is to avoid the dangers of the wheels taking the wrong grooves and opposite grooves. According to the invention, the groove and the flange or "tread" of the "open" point are made with a gradual depression commencing at the narrow end of the point, and reaching its lowest point at the place where the two grooves diverge, and thence rising to the normal levels of the groove, flange, or "tread" of the rail. Thus the "tread" of the wheel of the car, entering from the narrow end of the point, follows the depression of the rail and the flange, and is imprisoned in the depressed grooves until the opposite wheel has taken its proper groove in the loose point. Claim: The improvement in tramway points consisting in making the groove and the rail flange at the narrow or "taking on" end with a gradual depression reaching the lowest point at or about the place where the two grooves diverge, and thence rising gradually to the normal level.—No. 2191. February 7th, 1889. 6*d*.

Spring Making Machine.—*H. Knipping & F. Hohage, Altena, Prussia.*—This machine is designed for making spiral springs such as furniture springs. The whole process is effected automatically. The wire is led to and attached to the spools upon which it is wound, and when the winding is completed, cut off by automatically working shears. Fig. 1 is a front elevation, and Fig. 2 a plan of the machine. The different parts of the machine are worked by pieces attached to the shaft A. The disc B, with a groove cut in it, gives one spool the backward and forward horizontal action for discharging the completed springs. The cam C actuates the shears A^1, and the heart-shaped cam E causes the rack F to rise and fall, thereby working the gear wheels E^1 S. The gear wheels E^1 S work the screw G for oscillating the guide O, and also work the two spools H, P, the spool P being connected to the other gear by the bar F^1 and additional

FIG. 1.



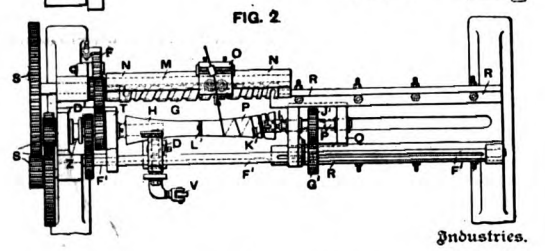


FIG. 2

Industries.

gearing G^1. The working of the machine is as follows:—At the beginning of the winding of each spring the spindle bearing Q, with the spool P and the guide O, are at the right end of their guides. The wire projects from the guide O, and is seized by the hook K^1 upon the spool P. The bearing Q is then moved to the left by the disc B, and the spools receiving motion from the rack F winds the wire upon the spools, and forms the spring. The spring is wound with more coils than is actually required to allow for the contraction when it is released from the spools. At the end of the winding the rack F reverses its motion, and by unwinding the spring allows it to contract in length and assume a larger diameter, and at the same time releases the end from the hook K^1 upon the spool P. On the backward motion of the guide O with the spring, the wire is brought between the shears and cut, so that the projecting end is of sufficient length to catch under the hook of the spool P as it moves forward again. Eight claims are made.—No. 14117. September 7th, 1889. 8*d*.

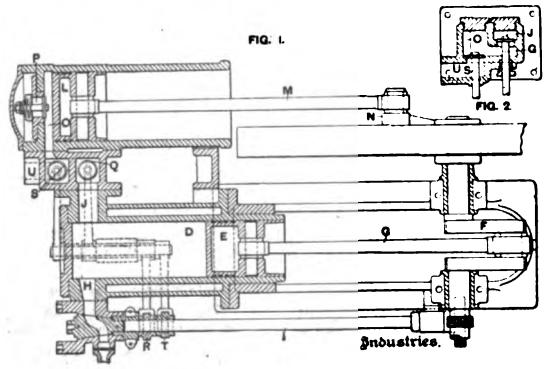
Healds of Looms.—*W. Ineson, Batley, Yorkshire.*—The object of this invention is to prevent the healds or gear of looms from rubbing or coming in contact with each other, and allowing a larger quantity of heald shafts to be employed. A series of loose vertical rods, wires, sticks, or other suitable substances are placed between each shaft at each end so as to leave a clear space between each shaft, forming slides for the said shafts, and so protecting the gear or heald yarns from rubbing. The rods, &c., are carried on cross shafts or rods by brackets attached to the loom frame. Claim: The use and employment of loose vertical rods or laths upon cross shafts as and for the purpose described.—No. 8206. May 17th, 1889. 6*d*.

Sawing Machinery.—*F. R. Lane, Woolborough.*—The novelty of this invention partly consists in the employment of air cushions to check the motion of the saws at the end of each stroke for the purpose of preventing vibration. A method of effecting this consists in making the backbone of the saw tubular, and with a stuffing box at each end. Through the stuffing boxes passes a fixed rod carrying two pistons so adjusted as to compress the air alternately at each end of the cylinder as the frame oscillates. The invention also relates to the method of driving the saws. A disc is fixed upon a shaft, which is revolved by belt pulleys, the disc having upon its face a swivel stud, which works between vertical guides fixed in the middle of the saw frame. Claim: In horizontal sawing machinery, the mechanism for driving the saw, consisting of a disc, provided with a swivel stud working in a yoke, of the afore-described rectangular saw frame, said disc being rotated by pulley and belt.—No. 4,638. March 16th, 1889. 6*d*.

Permanent Way of Railways.—*G. Robins, London.*—The inventor describes a method of preventing the longitudinal movement of switch tongues or rails. The inside of the jaws of every chair is notched or fluted, and the rails are rolled with corresponding ribs or projections, which fit in the notched flutes of the chairs. The ribs are rolled upon each side of the rail, and thus act as key fasteners to the wooden keys. Claim: In railway permanent way, providing teeth or ribs on one or both sides of the webs of the rails, and corresponding notches or channels on the inside jaws of the chairs.—No. 3575. February 28th, 1889. 8*d*.

Gas Engines.—*E. Repland, London.* (*P. Niel, Evreux, France.*)—This invention consists of a form of double-expansion engine, in which the products of combustion are mixed and expanded with air in a second cylinder. The object of mixing the air and exploded charge is to utilise the heat of the latter to expand the air and so produce greater pressure than the exploded charge would possess alone. In the cylinder D works the piston E, actuating with its rod G the crank F. The distribution of air and gas and the ignition take place through the lateral duct H, which is regulated by a tapered cock and shaft I, revolving once to two revolutions of the shaft. The valve box, shown in cross section by Fig. 2, establishes communication between cylinder D and air chamber O and between the cylinders and the conduit U. The valves are worked by cams R and T upon the shaft I. The air chamber O has a cubic capacity double that of the cylinder D, and its piston is connected to a crank pin N, situated upon the crank shaft directly opposite to the crank F. Whilst the piston E compresses its explosive charge, the piston L draws in air through the valve P. At the end of this first stroke the charge is exploded, and the piston E travels outward, doing work, and the piston L inward, compressing the charge of air previously drawn in. During the inward stroke, however, of the piston L the valve S is open half the distance of the

FIG. 1.



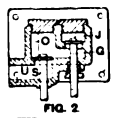


FIG. 2

Industries.

stroke, and thus half the air is allowed to escape. The air at the end of the inward stroke of the piston L is compressed to a pressure approximately equal to the pressure of the exploded and expanded charge in the cylinder D. The exploded charge and the compressed air are now mixed by valve Q being raised, and the heat of the charge coming into contact with the air expands the latter and increases the pressure of the mixed gases. As the pressure of the gases acting upon each piston is the same, and the area of the piston L is larger than that of the piston E, the extra pressure upon L causes it to perform work in the next (the third) stroke. At the fourth stroke the piston E draws in a fresh explosive charge, and the mixed gases in the cylinder K are discharged through the conduit U, and the cycle is then repeated. Claim: The application in gas motors of a second cylinder of greater volume than that of the gas motor, said second cylinder receiving a charge of air or other non-inflammable gas, a portion of which is compressed at the moment of escape of the products of combustion, which charge, by the action of the heat of the said products, expands, thereby producing additional motive force to act on the shaft, and consequently resulting in an economy of combustion.—No. 875. January 17th, 1889. 8*d*.

ELECTRICITY.

Dynamo Electrical Machines.—*W. T. Goolden, & H. W. Ravenshaw, London.*—According to this invention the commutator sections or strips are brought into the same plane as that in which is situated the side of the armature next the commutator or beyond the plane inwards of the armature side, and the armature wires, conductors, or windings are led down to, and are hooked or passed under the ends of the commutator strips and are fixed to them, so that the wires, conductors, or windings can be readily removed and replaced. The frame or support for the field magnets is preferably arranged on one side only of the armature, each magnet having its pole piece extending on both sides of the armature. The armature is of the disc type, and its core is preferably composed of a riband of soft iron wound with intervening insulation, on a frame, or hub, on the armature shaft. This core may be encircled with wood or other insulating material, which should be provided with notches to receive the coils of the armature wires, conductors, or windings. The winding may be done after the manner of the winding of a gramme armature. The commutator is preferably situated on the side of the armature opposite to that on which the frame or support for the field magnets is situated. The armature may be protected by covers between the field pieces. When it is desired to inspect or repair, the armature covers are removed and the armature is turned until the part to be inspected is brought opposite an opening. Claims: (1) In a dynamo electrical machine with disc armature a commutator so situated, or with its sections or strips so angled or arranged, that the points of connection of the sections or strips with the armature conductors are situated in the same plane, or behind the same plane, as that in which the face of the armature next the commutator is situated, and armature wires, conductors, or windings engaging with the ends of the said sections or strips; (2) the arrangement and combination of parts constituting a dynamo electrical machine as described.—No. 16710. October 22nd, 1889. 6*d*.

Dynamos.—*I. A. Timmis, London.*—This is an arrangement to prevent the effect of the varying speeds of dynamos and to keep the current practically constant. The principle of this arrangement is the employment of resistances which are automatically switched in at the desired moment. The resistances may be of any convenient form. The resistances are switched in automatically as the e.m.f. of the dynamo has reached such a value that current in the external circuit may be prevented from reaching such a limit as to be dangerous to the lamps or batteries in circuit. When a second dangerous speed limit is approached, a second resistance is switched in, and so on. To switch the resistances in, a long pull magnet is preferably employed, but any convenient shape may be used. Claims: (1) The arrangement of long pull magnets, electromagnets, or solenoids, with resistances automatically working in the field magnet circuit of any dynamo, either shunt, series, or compound wound, arranged and operating substantially as and for the purposes hereinbefore described; (2) an arrangement of long pull magnets, electromagnets, or solenoids, whose coils are connected up either as a shunt to the field magnet coils, or in series with the field magnet coils, and also in series with the resistances; (3) a long pull magnet or solenoid, with automatic cut-out contact pieces and resistance attached, as described; (4) the use of an electromagnet or solenoid, which has a diagrammatic pull, increasing in an equal ratio (practically) with the resistance it has to overcome.—No. 1535. January 28th, 1889. 8*d*.

Dynamo Electric Machines.—*A. Poleschko, St. Petersburg.*—The machine consists of an iron disc cut up in the direction of its radii into a large number of narrow sectors. The disc revolves between pole pieces having the form of narrow sectors on the sides facing the disc. Two brushes placed side by side rub on the periphery of the disc, and constitute the collectors. In the figures A is the core of the electromagnet, which is cast in soft steel in a single piece; D is the iron disc, which is made of one piece, and cut afterwards into small sectors from 60 to 100 in number. The disc is electrically soldered to the bronze nave H and the shaft B. The shaft B is made of aluminium bronze, and runs in steel bearings F, which are surrounded by bronze pieces E, the whole being supported in the arms C of the electromagnet. The object of making the shaft B of bronze is to avoid

FIG. 1.

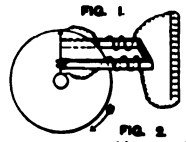

FIG. 2.

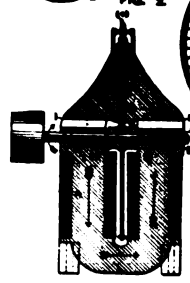

FIG. 3.

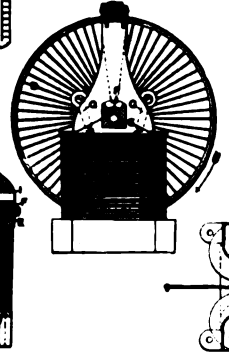

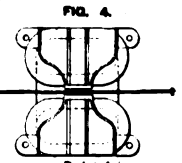

FIG. 4.

Industries.

the diversion of the lines of magnetic force in this shaft. The bronze pieces are used to separate the shaft from the magnetic centre of the poles of the electromagnet. The collecting brushes are attached to the top of the arms of the electromagnet as shown. Claims: (1) The rotary induced piece of machinery or armature exclusively of iron, in the form of an iron disc, cut up, in the direction of its radii, into a large number of narrow sectors; (2) the polar pieces having the form of narrow sectors on the inner side turned towards the disc, and condensing, so to speak, the magnetic flux along the radius of the disc; towards the outer side these polar pieces widen out, so that they present throughout a sufficient transverse section for the magnetic flux; (3) the system of the upper collector or brush in the form of two combs, side by side, and able to move independently of each other on the circumference of the disc, for the purpose of introducing into the circuit, and excluding therefrom the sectors of the disc, at the precise moment of the absence of current in the corresponding sectors.—No. 85. January 2nd, 1889. 8d.

MISCELLANEOUS.

Dye Extractors.—*F. Rhodes, Gomersall, Yorkshire.*—This invention relates to an improved form of apparatus for extracting the soluble colouring matter from dye-woods or other materials employed in dyeing. The inventor employs in combination with an ordinary dye vat and water heating and raising appliances, an extracting vessel of either rectangular or cylindrical form, one end of which is closed permanently and the other end is provided with a movable steam-tight cover secured by bolts and nuts. The extracting vessel is most conveniently used in a horizontal position, and is furnished with a perforated false bottom or strainer, upon which is placed the dye-wood or other material from which the soluble colouring matter is to be extracted. An inlet is formed at the top side of the extracting vessel for the admission of hot water or dye liquor, and an outlet at the bottom of the vessel. The temperature of the liquor contained in or passing through the extracting vessel is maintained by means of a steam coil or by blowing in steam or by steam jacketing. There are four claims.—No. 15558. October 3rd, 1888. 6*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

Digitized by Google

THE PROGRESS OF ELECTRICAL ENGINEERING IN 1889.

THE past year has been remarkable for the extraordinary commercial activity in electric light and heavy electrical engineering businesses. Most of the manufacturing firms have been as busy as they possibly could be, and have had a turn-out of from two to three times that of former years.

The greatest development has been in central lighting stations. In some respects, we fear, things have been going a little too fast. The public has been asked for, and has perhaps given, a good deal more money than can be very safely invested. Central stations have paid remarkably well in the United States, and will probably pay nearly as well in this country, but there seems to be no reason for such an extraordinary rush for provisional orders.

On the other hand, there is some chance of a kind of silly panic being spread by the untechnical press. They kill a man every now and then in the States by overhead high-tension circuits, having a bare apology for insulation; it is then taken for granted by energetic and sensational journalists that we are going to do the same in some mysterious way with underground mains, and even with low-pressure circuits. The rules and regulations in force in this country are so strict that it would be practically impossible to kill any but a most ingeniously suicidal customer. Though to electrical engineers this outcry about danger appears to be very silly and unnecessary, it must be remembered that it is of enormous importance. Electricians may know perfectly well that a properly arranged installation is far safer, both as to risks of fire and of life, than oil lamps, gas, or candles; but it must be borne in mind that the public knows a great deal less than nothing about electric lighting; that is to say, it has all sorts of wrong ideas which may be very difficult to eradicate. A public which solemnly reads the blood-curdling accounts of utterly impossible details of American accidents may at any time come to believe that the electric light is really dangerous; and it is utterly impossible for the electric light to make any headway in the teeth of adverse public opinion. This outcry in America has been especially directed against the alternate current system, and it seems to have been started by people interested in direct current systems. As a matter of fact there is no reason why the alternate system, even with a transformer in each house, should not be perfectly safe. The accidents in America are nearly always due to badly insulated overhead direct current arc-light circuits. In England we run very few overhead arc circuits, and when we do we insulate them properly, and put them out of reach of the public.

CENTRAL STATION LIGHTING.

We will now discuss our subject under its separate heads. Little need be said here about central lighting stations, as we intend to publish a series of articles on this subject in a few weeks.

Of the contractors for station plant we may mention the Brush Engineering Company, which has supplied a number of Mordey alternating current machines and transformers, both for this country and for abroad. Mr. Ferranti has supplied the large dynamos for the London Electric Supply Corporation, and a 150 h.p. machine for Messrs. Muir, Mavor, & Coulson's installation in Glasgow, and has also done a large export business, viz.:—Paris, Halle Centrale, three 150 h.p. dynamos; Paris Exhibition, one 150 h.p. machine. In course of construction:—Havre, two 300 e.h.p. machines; Troyes, one 150 e.h.p. machine; Melun, one 150 e.h.p. machine; Lens, one 150 e.h.p. machine. Sent to South America:—La Plata, two 150 e.h.p. machines; Rosario, two 150 e.h.p. machines; Buenos Ayres, two 150 h.p. machines. These two machines are now in course of construction. With the plants for Rosario and La Plata, Corliss vertical compound engines, made by Messrs. Hick, Hargreaves, & Co., Bolton, and Babcock & Wilcox boilers were sent out.

Messrs. Crompton & Co., Limited, have, during the past year, carried out the whole of the contract work for the Kensington and Knightsbridge Company, including the erection and part equipment of two large central stations, each of which when complete will eventually be on a scale sufficient to supply 130,000 10 c.p. lamps. These two stations are on the battery transformer system. At Chelmsford they have nearly completed a central station for lighting the town on the alternating transformer system. At Northampton they have secured the order for, and are just commencing work on, a central station, on the battery transformer system. At Swansea they are just commencing work for a central station on the same system. At Port Barry they have nearly completed a central station on the combined high tension series, arc lighting, and alternating transformer system. They have secured the contract, and are now commencing work, on a similar station for Folkestone, and have secured a contract, particulars of which are not yet settled, for a central station for the Westminster Electric Supply Corporation. In addition to contracts for the complete supply of central stations, they have obtained large orders for plant of the same nature for the Central Argentine Railway, through their agent in London for the Central Station in Gothenberg, through Mr. Calvert for the Liverpool Electric Supply Corporation, and for the Crompton Electric Supply Company of Australia. Messrs. Johnson & Phillips have contracted for plant for two stations in England, and one in Hong Kong, using dynamos and transformers designed by Mr. Kapp. Messrs. J. H. Holmes & Co. have sent out machines for a station in Spain, and complete installations for Australia and South Africa. Messrs. J. G. Statter & Co. and the United Electrical Engineering Company have also been busy in the same direction.

PRIVATE INSTALLATIONS.

Messrs. Crompton & Co. have fitted up no less than ninety-three installations, the total number of lamps in these being upwards of 11,500. Messrs. Drake & Gorham have also done a great deal of work last year. Among Messrs. Paterson & Cooper's more important private installations may be mentioned the Albert Institute, Dundee; the Pontardawe Tin Plate Works, South Wales; the Overton Paper Mills, Greenock; Messrs. I. and B. Stevenson's bakeries at Battersea; Kingswood Warren, Epsom, the residence of H. C. Bonsor, Esq., M.P.; the factories of Messrs. Davis, Moore, & Co., Leicester; and the wharf of the Dundee, Perth, and London Shipping Co., at Wapping. They have executed a large number of minor contracts, carried out wiring and extension work, and have several contracts still to finish.

Among the principal work carried out during the past year by Messrs. Woodhouse & Rawson has been installation work for the Paris Exhibition, Messrs. W. H. Smith & Son, Crosse & Blackwell, Peak, Frean, & Co., Savoy Mansions, Lord Ripon, Sir Frederick Carden, Salisbury Club, &c.; besides one or two large central stations.

Messrs. J. H. Holmes & Co. have had a great number of installations in mills and factories, including spinning and weaving mills, flour mills, paper mills, clothing factories, co-operative stores, chemical works, meat stores, wharves, collieries, science schools, &c., besides private houses and hotels. Besides these installations, the "Castle" dynamos have been supplied to a number of electrical engineers; altogether over 200 dynamos have been turned out in 1889, mostly of large size. A large number of Mr. J. H. Holmes' patent arc lamps have been sent out, one installation at an engine works with 25 arcs, and another at a shipyard with 20 arcs, besides many others. In addition to dynamos, Mr. J. H. Holmes' patent switches with switchboard, automatic switches, and various ship and other fittings, cargo and ship lamps, &c., have kept the works very busy.

Messrs. Verity, Messrs. Laurence, Paris, & Scott, and, in fact, most firms, have also been busy in this department.

A great deal of work has been done in ship lighting. Messrs. Holmes & Co. have, during the last year, lighted up thirty-five steamers. Many of the steamers have been fitted up with direct driven plant, the dynamos being coupled to vertical engines, both simple and compound. These run at from 200 to 350 revolutions, and have stood the test of very hot engine rooms and tropical climates without injury. Projector lights for the Suez Canal have been fitted in many vessels. Besides those already fitted, the firm have orders now on their books for the lighting of twenty-four steamers.

Messrs. Paterson & Cooper have supplied more machines than in any former year, both rope and direct driven. Among the steamers fitted by them may be mentioned the "Curlew," "Pladda," "Ardle," "Dean," "Modjeska," "St. Magnus," "Red Sea," "Rajah Brooke," "City of Venice," and yacht "Tighnamara." The end of the year finds them with orders for the lighting of several ships on hand.

Messrs. Crompton & Co. have supplied several sets of plant to the English and Dutch Admiralty. They have fitted up eleven steamships complete, and supplied the steam dynamos for the White Star ships "Teutonic" and "Majestic." These two last are probably the lowest speed direct-driven sets ever constructed, the actual running speed being 170 revolutions for 110 volt lamps.

Messrs. King, Brown, & Co. have put in a number of their engine and dynamo sets.

ELECTRIC TRANSMISSION OF POWER.

The electrical transmission of power does not seem to go forward as fast as it ought. Some work has been done, but there seems to be little enterprise in the electrical engineering industry in this direction. With one or two exceptions the leading firms do not really advertise or push their motors, and the public—and in fact a good many engineers—still cling to the old fallacy that a motor should be designed quite differently from a dynamo. Nearly the whole onus of the transmission of power business is left upon the shoulders of one firm, which makes a specialty of it and carries its burden very successfully. We should be sorry to see other firms which have not spent so much time and money in bringing electrical transmission into notice taking away any of Messrs. Immisch's work, but we would like to see them helping to push that branch of the business and creating more demand.

Messrs. Immisch & Co. find a steadily increasing demand for electrical plant for transmission of power, both at home and abroad. During the year this firm has more than doubled the output of the preceding twelve months. Amongst the plants turned out are a 70 h.p. hauling plant for St. John's Colliery, Normanton; a 30 h.p. pumping and hauling plant for Llancoch Pit, Pontypool; a 30 h.p. pumping plant for the Shale Mines, at West Calder; a 35 h.p. pumping and winding plant for tin mines in Bohemia; a 40 h.p. fan driving plant for Bohemia, &c.

Messrs. Mather & Platt have also done some work in the electrical transmission of power, and a few other firms have done anything that has come in their way, but to Messrs. Immisch belongs the credit of advertising and pushing this branch of the business. They have also developed a new branch of electrical engineering in their electric launches and charging stations on the Thames. The demand was so great during last summer that they intend to increase the little fleet of launches and the number of charging stations. There will then be four floating stations and eight or ten launches. The smallest carry about twenty people, while the largest (the "Viscountess Bury") is licensed to carry a hundred and fifty.

ELECTRIC TRACTION AND TELPHERAGE.

Electric tramways are now beginning to show signs of rapid progress in this country at last. The saving in comparison with horse traction, even if overhead wires are not allowed, is so great that there cannot but be a great future for electric traction. Traction has, like many other branches of electrical industry, been kept back by being to some extent taken up at first by the wrong people.

If a man comes forward and says he has no special invention or patent, but that he can work an electric tramway with the machinery in the market a good deal cheaper than it can be done by horses, the capitalist will not listen to him; but if an enthusiast with a wild scheme, and a system of his own which is to do impossible things, springs up, money is put in and a failure results, which discourages all advance for a year or two till the matter is forgotten. Good solid work is now beginning, and electrical traction is at last looking very promising.

The Electric Traction Company, in connection with Messrs. Immisch & Co., have been running self-contained tramcars on the North Metropolitan lines, between Barking and Canning Town, continuously for more than seven months. At the end of November, when five cars were running, the horses were withdrawn, and the service depended entirely upon the electric cars. Each car makes on an average 60 miles per day, so that the possible car mileage per week is about 2,100. The total mileage yet made is about 40,000. The cars have kept the schedule time within about 2 per cent. The engineers report that the Electrical Power Storage Company's plates are standing the rough usage much better than they expected. Indeed, the chief difficulty experienced has been due to faulty burning of the lugs to the cross-bars. Since the cells have now been in practically constant use for about seven months, the figures obtained are of some commercial value in estimating the probable cost of electric traction by accumulator cars. After carefully considering these, the Electric Traction Company feel satisfied that their original estimate of 4½d. per car mile is well within the mark.

The United Electrical Engineering Company have been engaged on the Northfleet series traction line, which has already been described in this journal, and they have also a good deal of material in hand for a series tramway for Italy. A rigid rail telpher line, having the exceptionally heavy grade of uniformly 1 in 11·5, has also been erected by them. It reaches from the Wood Green Station of the Great Northern Railway up the hill to the Alexandra Palace, and demonstrates the suitability of telpherage for passenger and heavy goods traffic under more onerous conditions than had previously been very generally expected. A line of a little over a mile and a quarter in length, for the transport of 1,000 tons of tin ore per week, is now in course of construction at the well-known Eastpool Tin Mine in Cornwall. An order is also in hand for an equipment for a telpher line in Rome. Telpherage is thus making active progress, and contracts are in the course of negotiation for South Africa and elsewhere.

Electric traction on a still higher scale is in progress in the Thames Subway, which is an electric railway, and

Digitized by Google

is being fitted electrically by Messrs. Mather & Platt. Trials under power have already taken place, the locomotives being tested with an artificial load of pig iron. Except a trifling hitch due to an armature, we believe everything is going perfectly.

Progress in Inventions and Designs.

Very little has been done in the way of striking inventions during the last year; engineers have been too busy in meeting the enormous demands for machinery of existing patterns to have been able to give much time to its improvement. It seems as if there was little to be done in the way of invention in such things as dynamos and motors, but designs have been greatly improving. Messrs. Chamberlain & Hookham have been perfecting M. Housman's dynamos with reversing pole-pieces. These machines are said to need no movement of the brushes when the load varies, and to be free from sparking at all loads. Mr. Kapp has introduced a neat end connection for drum armatures. Messrs. Crompton & Co. are said to be introducing Fritsche dynamos for central station work.

Probably more progress has been made in alternating motors than anything else, but nothing has been published, and the results of last year's work will not emerge from the secret archives of the Patent Office for some months. Mr. Mordey has propounded the theory that an alternate current motor should be exactly like an alternate current dynamo, but should have as little armature resistance and as little self-induction or armature reaction as possible, and he has many followers. Others dispute this. Besides the Brush Company, Messrs. Goolden & Co., Mr. Ferranti, and one or two other firms have been carrying out experiments on alternate motors.

Engines.

Messrs. Marshall, Robey, Davey Paxman, and Crossley Brothers have been, of course, supplying engines and boilers as usual, but in greater numbers. Messrs. Crossley have introduced lifting valves instead of slides in their larger gas engines, and they claim that engines above 4 h.p. can be run direct—that is to say, without accumulators—without any flickering of the lamps. The great advance of electric lighting has been chiefly in connection with central station work, so there has been an enormous demand for high speed engines, though many engineers prefer slow running engines, generally with Corliss gear, and belt or rope driving. To give some idea of the enormous demand for high speed engines for central stations and for ship lighting, we may instance Messrs. Willans & Robinson. They had a fire at the end of 1888, and began 1889 with no tools and hardly so much as a connecting rod in stock. In spite of this, their orders have approached 18,000 h.p., of which 4,000 is for ship work. Most of these engines have been delivered. The larger work of this company for the past year has been a series of engines for the St. James's and Pall Mall Company, to whom Messrs. Latimer Clark, Muirhead, & Co. are the contractors. Here there will be ten engines of 200 i.h.p. each, and ten of 80 i.h.p. each. Messrs. Willans & Robinson are also carrying out a very complete scheme of duplicated steam pipes for this installation. We append a list of the engines supplied by this firm:—For Messrs. Crompton & Co. (for the Kensington and Knightsbridge Company) a large number of engines have been made, aggregating over 1,200 i.h.p., while for the Electric Construction Corporation (for the Metropolitan Electric Light Company) over 3,500 i.h.p. have been set to work in, or got ready for, the new central stations in Rathbone Place and in Manchester Square. On behalf of the Chelsea Electricity Supply Company, the Brush Electrical Engineering Company has been a customer for six engines of 70 h.p. each, and the station of Messrs. Gatti, in the Strand, already furnished with about 450 h.p. of these engines, is being supplied with an additional engine of 140 h.p. through Messrs. Mather & Platt. The neighbouring installation at the Surrey Theatre is fitted with Willans' engines and Siemens' dynamos. Messrs. B. Verity & Sons' almost deserves to be ranked as the central station of the year, including as it does three engines of 200 h.p. each and one of 70 h.p. For the Liverpool Electricity Supply Company, under the management of Messrs. Holmes & Vaudrey, this firm has during the year supplied six engines of 200 h.p. each, besides some of 80 h.p. During the year 140 h.p. belt-driving engines have also been made for the new station of the Taunton Company. For the Corporation of Bradford two engines of about 160 h.p. each have been supplied. No less than forty-two comparatively large engines—namely, 200 h.p. at 350 revolutions—have been made during the year. They have also made a large number of small engines for the Navy, for merchant service, and for private installations, but there are too many of these to enumerate.

Cables.

The output of cables has naturally kept pace with the development of central station work. Messrs. Siemens have been supplying large quantities of cable to Bradford, and to the London Electric Supply Company, and to other stations. The Fowler-Waring cable has also been coming rapidly into favour. The question of the best insulation for underground work is of the greatest importance, and it is a little doubtful whether rubber, paraffin, bitumen, or such things as rosin oil will prove the best in the end. Messrs. Siemens adhere to rubber, and so do the Silvertown Company; while for very high pressure Mr. Ferranti depends on paper soaked with ozokerit. Messrs. Callender have supplied cables for the Liverpool Supply Company to the following stations—Whitehall, Strand, Chelsea, Bath—and for some seven or eight foreign supply companies. They have also supplied a large quantity for colliery and for ship work. The mains at Kensington Court and St. James's are, as is well known, strips of bare copper resting in stoneware wire insulators. The various systems of mains and their advantages and disadvantages will be more fully discussed at some future time.

Train Lighting and Electric Brakes.

Another very backward industry is train lighting. Train lighting has suffered in the same way as many other branches of electrical engineering. It was neglected early in the day by the lighting engineers, and was taken in hand by small firms with the unlimited enthusiasm which often accompanies ignorance of the real difficulties, and it has in some cases been rather a failure. On the other hand, it was shown to be a complete success on several railways some years ago. Pintsch's compressed gas is a serious competitor; but every traveller wants to see either the electric light or gas in use, instead of the miserable oil lamps. Mr. Timmis has been pushing forward as much as possible against the lethargy, and the dead weight of opposition, but train lighting does not even yet go as it ought. Messrs. Timmis & Forbes have also succeeded in getting an electric continuous brake tried, and it has been very successful. When the electric light is in common use on trains the electric brake will probably supplant the air brake. Electric brakes have been frequently proposed during the last ten years, but could not come into use because there was no source of electric power available. If there is a dynamo or storage cells on every train there is no difficulty in applying electromagnetic brakes. A pressure brake demands a steam engine and a pump, an electric brake needs a steam engine and a dynamo, but they also supply the lights, so that a train fitted with the electric light and electric brakes is very much simpler. Messrs. Dorman & Smith and some other firms have also been doing good work in train lighting.

Electrometallurgy.

Messrs. Crompton & Co. have turned out a good deal of electro-deposition machinery, including a 60 volt 2,500 ampere machine.

Messrs. Woodhouse & Rawson have taken up the Elmore deposition process. An English company has been formed, and appears to have very good prospects. It is rumoured that the same process can be applied to another very important metal. Messrs. J. H. Holmes & Co. have also made several large electro-deposition dynamos.

Electric Welding.

This industry has not yet started commercially in this country, but will do so very soon. A syndicate has been formed to push the industry in this country, and a small plant is fitted up in Fanshaw Street, where welding up to two inches or so diameter is done. We shall have more to say about this at some future date.

Miscellaneous.

In measuring instruments, Sir W. Thomson has been adding more links to his ever-lengthening chain. Messrs. Goolden & Co., the Walsall Co., Messrs. Siemens, and other makers have also been turning out large numbers of instruments. Meters have been in great demand. Messrs. Chamberlain & Hookham's output has been trebled, and these meters are alone in use in Liverpool, Leamington, and Derby, and are in use in London, Bradford, and elsewhere.

Mr. Ferranti has now 120 meters at work in Brighton and 120 more mercury meters are at work on the London Electric Supply Corporation Station. He has between 400 and 500 more on hand. He has brought out a new form under patents of his own and of M. Borel, and of Mr. Arthur Wright. It is rumoured that the Borel patent covers all meters of the electrical tourniquet type.

A very large number of Aron meters has also been sold. Messrs. Laurence, Paris, & Scott, the Brush Engineering Company, and Mr. Edmundson have also been perfecting meters.

Litigation.

Very fortunately there has been little money wasted over lawsuits. Three very important decisions have been given. The appeal judgment in favour of Edison's patent leaves the Edison-Swan Company in possession of the field in incandescent lamps. On the other hand, the so-called compound winding and Gaulard and Gibbs' transformer patent have been held invalid. The last two are still under appeal, one to the Court of Session, the other to the House of Lords.

THE PROGRESS OF CHEMICAL INDUSTRY IN 1889.

Our annual review of the progress of chemistry for the past year anticipates the complete official statistics and other returns for the twelve months, but we have ample data for making a general statement to the effect that the position of industrial chemistry has been maintained in this country during the year which has just closed. When manufacturers in this country realise that the conditions of the time necessitate—for a successful struggle for survival in the competition with rival nations—that they must educate themselves in the progress of scientific knowledge, then they will be in a position to utilise the discoveries of the workers in pure science for the advancement of the wealth of the country. Our continental rivals have already taken steps towards this combination of pure and applied chemistry, and have in a great measure broken down the division which existed between the two, and the scientific adviser is there seen to be indispensable to the manufacturer of chemical products. The intelligent workman holding the position of works chemist in some cases is useful in a stereotyped manufactory, but advance and development of new processes and an increase in the efficiency of the industrial machine can only be effected by research and the employment of capital in scientific speculation.

The statistics for the summer months of the past year show in the alkali trade a slight falling off, both in exports and imports, as compared with the corresponding period of the previous year, and there has also been a diminution in the quantity of bleaching materials exported. The low prices which prevailed during the past year have been unfavourable for the development of trade, and have caused the closing of several of the smaller alkali works. In the annual report of the Chief Alkali Inspector we note that the number of alkali works in Great Britain and Ireland under inspection have decreased from 1,066 in 1887 to 1,057 in 1888, and that there are indications of the gradual extinction of all the minor works, while the manufacturers who have available capital, by extension of their already large works, are able to adopt more economical processes, and thus maintain their business, even at the prevailing low prices. The erection of Chance's sulphur recovery plant by several of the important companies involves the expenditure of much capital, and, while giving a new lease of life to the larger Leblanc works, extinguishes the small manufacturer using the same process. Gossage's new process for the making of soda by heating the sulphate and salt with small coal, and subsequent treatment with carbonic acid, commends itself to the small capitalist as not requiring the elaborate plant of the Chance's system, but it at present requires further trial to demonstrate its economic advantages. Notwithstanding these improvements the ammonia soda makers seem still to be taking the trade from those who keep to the older process. Improvements in the recovery of sulphur have also been accompanied with improvements in the construction of the Leblanc plant, and Lunge has recently described a method for utilising the heat of pyrites burner gases for concentrating the chamber acid outside the Glover tower by an indirect system of heating in pans or lead piping. This waste heat is thus utilised before the gases are led into the Glover tower, where they subsequently have merely a denitrating action. The trade in Sicilian sulphur has likewise diminished in the year, partly owing to the low prices which have been current, and partly, no doubt, to the newer processes of sulphur recovery, both by the alkali manufacturer and in the coal gas industry. These last two sources of sulphur will necessarily reduce the demand for Sicilian sulphur. In connection with the manufacture of sulphuric acid from pyrites we note that the French Society for the Encouragement of Arts and Sciences has offered a prize of 2,000fr. to the manufacturer who shall be the first to bring into commerce a sulphuric acid manufactured from pyrites which shall be perfectly free from arsenic. The production of hydrochloric and sulphuric acids has largely increased in France during the last two years, and these industrial prizes will further stimulate the industry. The operations of the Salt Union in raising the price of salt in the spring from 7s. 6d. to 13s. 6d. for common salt has also

Digitized by Google

militated against the alkali manufacturers, and only those who are fortunate enough in commanding brine wells of their own have had the advantage of a supply of salt at a reasonable price. The year closed with the expiration of the Bleach Association, which has controlled the price of this important bye-product for the last seven years. Although a free competition in the price of bleaching powder will undoubtedly have the effect of considerably lowering the price of this commodity, it seems improbable that, with coal, salt, and wages all dearer than seven years ago, the previous low rates will return. The Society of Encouragement of Arts and Sciences in France has also offered a second 2,000fr. for improvements in the manufacture of chlorine, and it seems probable that some electrolytic process for preparing this bleaching agent directly from salt, similar to the laboratory method devised by Hempel, may eventually be the death knell of the Leblanc process. Ozone may also before long be an industrial bleaching agent, and may possibly be economically obtained from the cheap oxygen due to Brins' process. France also stimulates research in this direction by offering a prize of 2,000fr. for the best industrial application of this allotropic form of oxygen. The sulphite methods for bleaching wood pulp for the paper manufacture has also, undoubtedly, curtailed the use of bleaching powder in the paper making industry. These remarks will likewise apply to the use of soda in paper making works, as although bleaching powder is at present lower in price, soda has increased in value and is likely to become still higher, and will thus cause the paper maker to turn his attention to other bleaching agents.

The Bleach Association was followed by a combination of the hydrochloric acid manufacturers, and they, after demanding higher prices for this acid, have found it advisable to again act independently. An increase in the price reduces the consumption, as vitriol is then found cheaper for a variety of purposes, and is used in preference. If the consumption of the acid can be increased by moderate prices, there will be less necessity for the manufacture of a larger quantity of bleach, and thus a considerable lowering in the price of this article would be avoided. In 1888 the price of bleaching powder was £7 7s. 6d. per ton; now it has reached the low value of £4 12s. 6d. to £5 for soft wood casks; and the export of bleaching materials during the last few months has declined, especially to America, being 3,585 tons less in the eleven months ending November. Brock & Minton's lime sprinkling machine, for absorbing the residual chlorine in the bleaching powder chambers, deserves to be mentioned in connection with this industry, as the patentees state that they have obtained about 200 tons of additional bleach at their works by its use. The increase in the shipments of nitrate of soda to this country, to which we shall allude later, renders nitric acid a cheaper commodity, and suggests that the processes for the preparation of chlorine by the action of nitric acid upon hydrochloric acid may be found cheaper than that of oxidation by manganese dioxide, especially as the nitrous fumes produced in the process can be recovered and utilised in the leaden chamber and in other ways. The Chief Alkali Inspector has also drawn attention in his annual report to a valuable improvement on the Weldon plant, whereby the acid liquors are completely neutralised in the stills by Weldon mud. This method gives a considerable saving in limestone, and enables a ton of bleach to be manufactured from 45cwt. of salt instead of 50 as formerly. Gamble has also patented a method for the manufacture of chlorine and hydrochloric acid from a mixture of magnesia and magnesium chloride by the action of strongly heated air similar to the Weldon Pechiney process, and a process has been devised for obtaining these bodies by the joint action of air and sulphurous acid on salt containing manganese chloride and dioxide, while Salzburg proposes to use carnallite as a source of hydrochloric acid and chlorine. In connection with the alkali trade, we note that Messrs. Chance, and Messrs. Parnell and Simpson, have patented several improvements in their respective processes for the recovery of sulphur from alkali waste, and Hammill, by the refrigeration of the liquors obtained in the manufacture of potassium chlorate, has succeeded in obtaining a much improved yield of chlorate. The two important artificial nitrogenous manures—nitrate of soda and ammonium sulphate—continue to be placed on the market in ever increasing quantities. In 1888 no less than 122,785 tons of ammonium sulphate were produced in this country, and the returns for the past year will be of a much greater magnitude. This compound is now obtained as a bye-product in all the larger gas, iron, shale, and coke works, and in the Chief Alkali Inspector's report a favourable notice of Mond's process is given, in which it is stated that 66lb. of ammonium sulphate is obtained per ton of slack from the coal burnt in his firm's furnaces. A method for the recovery of the nitrogen as ammonia from the cyanides of black ash is also proposed by Hawliczek. The nitrate industry has also developed at an unprecedented rate, and now the output has to be restricted and the price lowered to £8 10s. per ton. The total shipments from South America since 1830, when only 800 tons were imported, amount to 8,257,900 tons; and Messrs. Laird & Adamson give the following statistics, showing the growth of the trade during the last few years:—

Year.	Ships.	Quantity.	Consumption.
1886	371	437,500	486,000
1887	516	680,600	686,000
1888	533	745,700	700,000
1889	—	903,000 (estimated)	

The history of the Chilian nitrate industry is of a complicated nature, and the political and speculative interests which have been at work have, in all probability, handicapped the progress and prosperity of the industry. The Rothamstead experiments in this country, and the researches of Berthelot on the fixation of nitrogen by vegetable soil, and Debérain's statistics on the losses and gains of nitrogen in the experimental field of Grignon, as well as the admirable special treatises by Paul Wagner and others, all tend to impress upon the agriculturist the advantages to be derived from the application of a nitrogenous manure to his crops, and render the further development of this industry only a matter of time. It is well known that the Peruvian guano deposits are rapidly becoming exhausted, while the development of the Stassfurt potassium salt industry and the cheapness of Thomas slag as a source of phosphorus contribute to render the farmer more willing to avail himself of these artificial fertilisers. The consumption of nitrate for agricultural purposes is only in its infancy, and although at present more largely used on the Continent than in this country, it will not be long before the English farmer finds it a necessity for successful farming, and large quantities will be exported again from this country to our grain-growing colonies in Australia and New Zealand and the tea and coffee districts of India.

We have not space in the present article to trace the development of metallurgical chemistry during the year. The manufacture of aluminium and its alloys by several processes is now established on a commercial basis, and the new metal is gradually being introduced to the public in a variety of forms. The metal nickel is also being experimented with, and Mr. Riley, in the beginning of last year, drew attention to the valuable properties of the nickel steel alloys, which indicate that they have a future before them. Recent discoveries of nickel in large quantities at Sudbury, in America, and in the Urals will help considerably to a more general use of this metal. Cobalt has been used successfully as a substitute for nickel in electroplating, and Krüss and Schmidt have confirmed their statement with regard to the presence of a new element in the commercial samples of nickel salts which they have examined. The chemistry of the blast furnace has been discussed by Sir Lowthian Bell, and a valuable paper on the advantages to be derived from the use of lime in the place of limestone as a flux in blast furnace practice was communicated to the Institution of Mechanical Engineers by Mr. C. Cochrane. Under the heading of fuel and gas, the year has been signalised by a discussion in this country on the merits of water-gas, and it has been adopted at some works, where great heat has to be applied to a limited area, with success. The poisonous nature of this and producer-gas necessitate extra precautions in its use, and we note that a patent has been obtained by Fox and Blass for adding the vapours of volatile liquids to the gas, which will give it an odour and render it possible to readily detect an escape. The Ramsgate Corporation have expressed satisfaction at the experiments of Mr. Valon on the use of oxygen for removing the sulphur compounds from coal gas, and is proceeding with the erection of plant for the treatment of the town's gas supply by the new process. The Dinsmore system of gas-making, in which some of the tar produced is utilised by mixing it with the coal used in the retorts, has been pronounced successful, and the difficulties at first met with through blocking of the pipes with undecomposed tar has been overcome by means of a specially constructed cooled passage for the condensation of volatile products. Processes are being developed for the recovery of sulphocyanogen and ferrocyanogen compounds from the spent oxide of gas purifiers, and at Belfast the Claus process is at work, in which these valuable cyanogen compounds and free sulphur are recovered in the coal gas manufacture. The importation of petroleum has undergone a change by the substitution of tank steamers for the American trade with Newcastle, and the Anglo-American Oil Company have recently commenced operations in London on the same plan. In tar products prices have improved considerably during the year, and tar oils, pitch, and tar are all higher than they have been for several years. Pitch, for example, was selling in December, 1888, at 25s. per ton, while the price now is about 36s. Solvent naphtha has likewise shown a marked increase in price. The market in carbolic acid is, however, much weaker, and there are no inquiries for this acid at present. The stagnation in this department seems due to the action of the French Government in abandoning the idea of using this product for the manufacture of explosives. This remark likewise applies to picric acid, which has varied in demand with that of carbolic acid. The Badische Anilin und Soda Fabrik have introduced during the year a pure carbolic acid made synthetically. Benzene and anthracene remain steady, and the increase in the value of pitch is due in a great measure to the large quantities which have been exported to America during the year for the manufacture of patent fuel in that country. This demand, however, is not likely to be maintained, as there is every probability of tar distilling plant being erected in that country. Creasote is now largely employed for illumination in the larger industrial oil lamps. In Germany, the trade in tar products is still favourable, and aniline dyes improve slowly. The imports to this country of coal tar colours (aniline, alizarine, and other coal tar dyes) has increased from £262,101 in 1888 to £298,859 for the corresponding six months in 1889. It is impossible to discuss the many new dyestuffs which have been introduced during the year, but we cannot omit to allude to the starting of a new Quarterly Journal by E. Börnstein called *Die Farben Industrie*, which is devoted to this rapidly developed industry. The manufacture of induline colouring matters soluble in water, of the primuline colours, and of colouring matters obtained by the action of diazo-compounds on the naphthols and naphthylamines have all been patented during the year, and considerable improvements have been made in dyeing with mixed colours. Hirsch has contributed a paper on the theory of the aniline blue process, and Dommergue has given a valuable summary of the methods for detecting the colours of dyed wools. In pharmaceutical preparations we may mention the extended use of sulphonal and antipyrine, and the introduction of thiocamph by Emerson Reynolds as a new disinfectant, and Lister's suggestion to substitute the double mercuric cyanide for the chloride in antiseptic treatment. The efforts of the London Chamber of Commerce in obtaining a drawback on spirituous preparations, and the permission to remove damaged tea in bond for the preparation of caffeine in this country, which we alluded to in our annual review of 1888 have been beneficial to the manufacturers of pharmaceutical products, and these facilities are enabling the British manufacturers to compete with Germany in exporting chemicals of English manufacture to Brazil and other countries.

Considerable progress has been made during the year in the manufacture of explosives, and many new compositions have been patented. Most of these new explosives are the so-called nitro-compounds of the carbohydrates, and are prepared by nitrating woody matter, vegetable fibre, cellulose, straw, paper pulp, or starch. The nitrated compound is then dissolved in acetic ether, or other solvent, and can then be reduced to a powder, or made to assume a cylindrical or granular form by distilling off the solvent. By mixing dynamite or gun-cotton with nitrate of urea a smokeless explosive has been obtained, and Schückher, in Vienna, has patented the manufacture of a smokeless powder from nitro-starch, saltpetre, and nitrobenzole. Hengst's improved safety smokeless powder is produced by nitrating pulped straw and granulating the products. We alluded in our issue of the 3rd inst. to the recent progress made in our knowledge of the constitution of cellulose by Cross and Bevan.

We cannot conclude this brief summary of the progress of industrial chemistry without drawing attention to the work and formation of several new companies for working novel chemical processes. Brins' Oxygen Company have recently shown that oxygen gas when introduced into a bleaching liquid considerably augments its bleaching action, and also that the gas has the effect of maturing raw and young whiskies. Hannay (of the White Lead Company) has patented a process for the direct oxidation of galena to white lead sulphate, which is found to possess all the qualities necessary for a good substitute for ordinary white lead, and Groth has devised a method of tanning by electricity, which has been satisfactorily at work at Messrs. Tebbitt's tannery at Bermondsey during last year. The British Tanning Company has also been formed to acquire the patents of Messrs. Worms & Balé, of Paris, in this country. This process consists of subjecting the hides in contact with ordinary tanning materials (without acids) to the action of a current of electricity in a revolving drum.

In theoretical chemistry points of interest seem to be the formation of an aluminous compound $2NaF.AlF_2$ by Hampé, the production of a new acid from tin by dialysis having the constitution $H_2Sn_2O_7$ (W. Spring), the new methods for obtaining the elements silicon and boron by the use of magnesium powder, described by Gallermann, and the continuance of the researches on the molecular weight of solids by means of Raolt's law.

IMPROVED MACHINES FOR TESTING THE STRENGTH OF MATERIALS.

CONSTRUCTED BY MR. ARTHUR H. KUHLMANN. ENGINEER, LONDON.

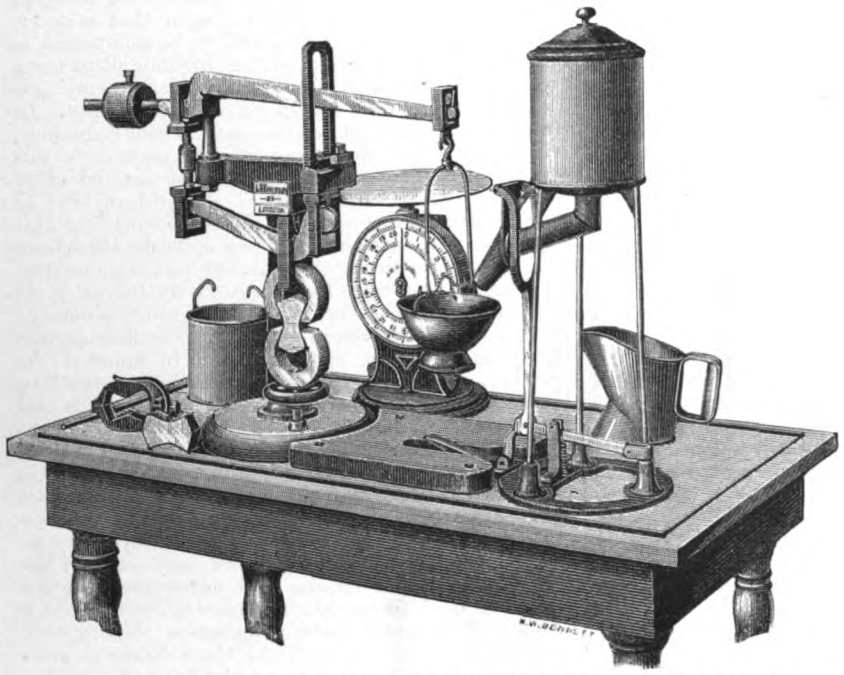

FIG. 1.—MACHINE FOR TESTING THE TENSILE STRENGTH OF CEMENT.

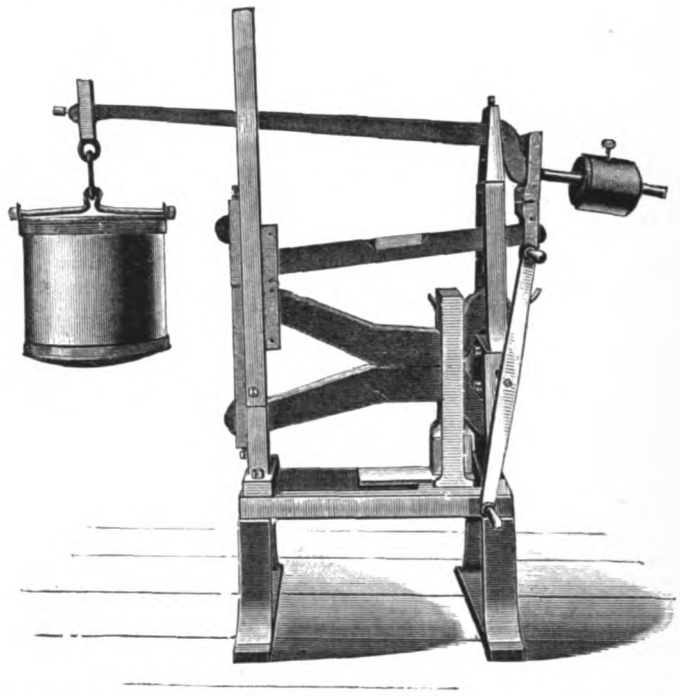

FIG. 2.—MACHINE FOR TESTING THE CRUSHING STRENGTH OF CEMENT.

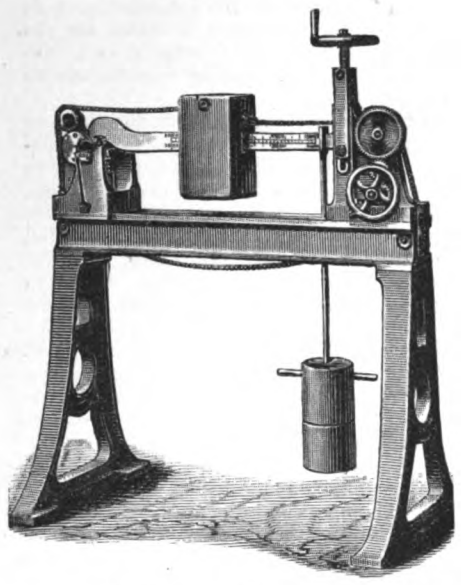

FIG. 3.—MACHINE FOR TESTING TRANSVERSE STRENGTH OF CAST IRON BARS.

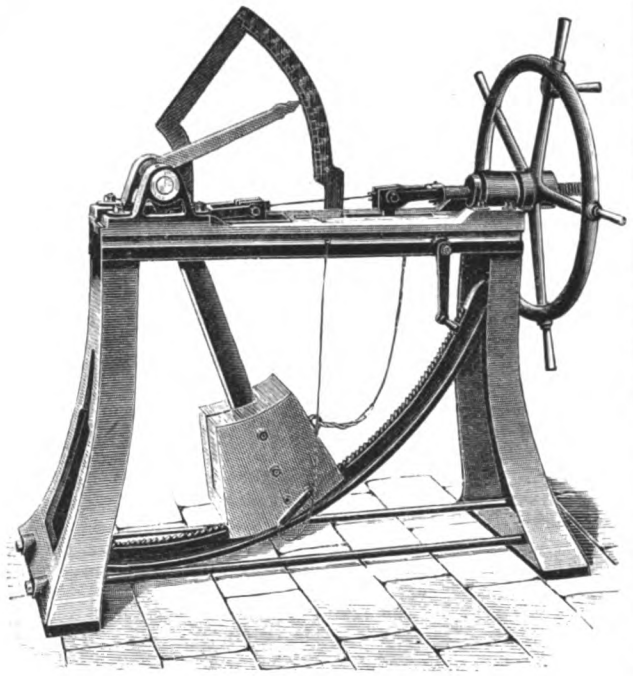

FIG. 4.—MACHINE FOR TESTING WIRE.

KUHLMANN'S TESTING MACHINES.

WE illustrate above a number of testing machines which are being made by Mr. Arthur H. Kuhlmann, 23, Great St. Helen's, London, E.C. The machine illustrated in Fig. 1 has been on the market for a year or two, and has been adopted by many of the leading contractors, railway authorities, harbour boards, &c. The remaining machines are now being placed on the market in consequence of the success of the first-named.

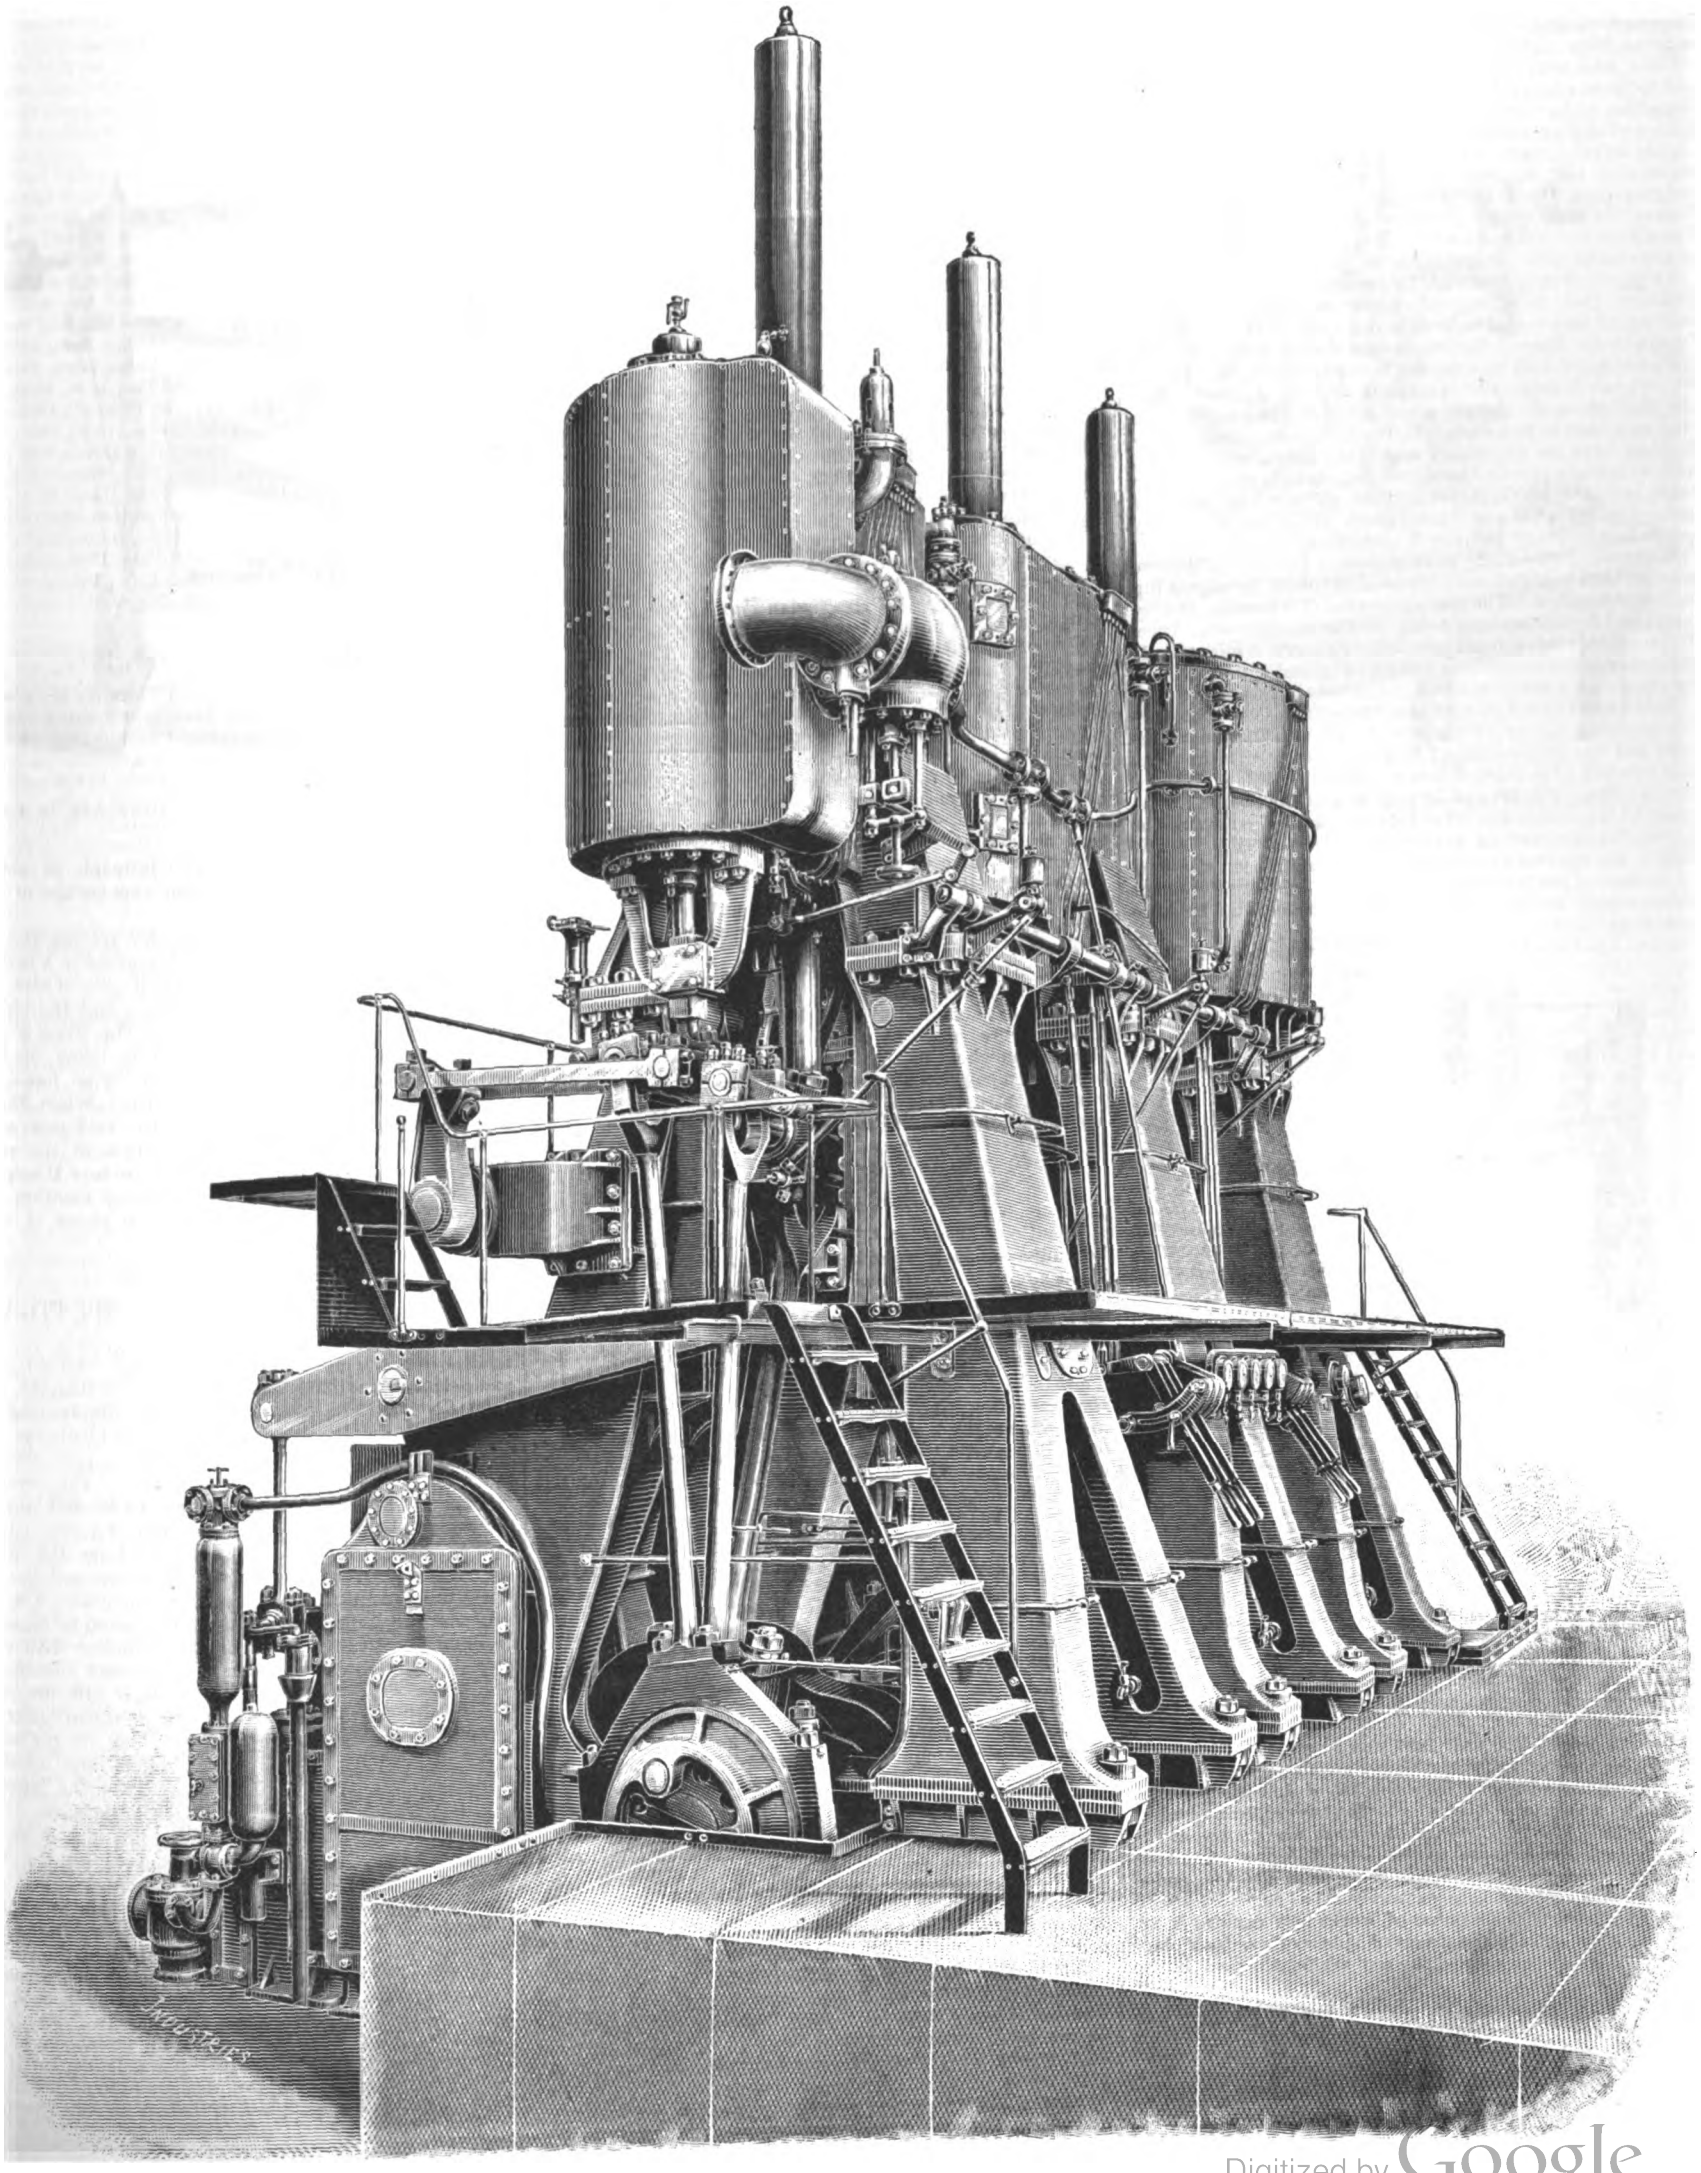
In Fig. 1 is shown a general view of a machine for testing the strength of cement. The briquette of cement is held between two clamps, one of which is fixed to the base of the machine and the other to the end of a lever. This lever is in gear with another lever above, at the other extremity of which there is a pan. The load is gradually added to the pan, and the stress thus generated is multiplied by the levers to fifty times the weight of the load in the pan. The load which is most convenient is No. 6 fine shot, and it is slowly poured from a self-acting shot-run at the side of the machine. The apparatus has been successfully used at a number of waterworks and harbour works, at University College Engineering Laboratory, and at many other places.

The machine which we illustrate in Fig. 2 is intended for testing the crushing strength of cement. The brick of cement is placed at the bottom of the short standard shown in the illustration, and by means of the double system of levers the load in the can is made to exercise a very powerful pressure upon the cement. This machine is made in a much stouter form than the one described in Fig. 1.

Fig. 3 shows a simple machine for testing the cross-breaking strength of cast iron. The load is a heavy weight which is moved along a horizontal arm, and the stress thus generated is multiplied in any proportion from 1 to 10, according to the position of the weight. The piece to be tested is 8in. long and $\frac{3}{8}$in. diameter, and the testing is therefore a matter of comparative ease. The machine generally is constructed on the principle of obtaining accurate results with a minimum expenditure of money and time.

In Fig. 4 we show a machine for testing the actual tensile strength of wire. The clamps are in a horizontal position, and are adapted to hold all sizes of wire. There are no binding screws on the clamps, and the centering of the wire is done automatically. The stress is put on the wire by the handwheel, and is taken up by the counterpoise. The stress is shown by an index, which is connected with the counterpoise. When the wire breaks the pawl pieces fall into the rack gear, and the counterpoise and index-finger remain in the position occupied at breakage. As an indication of the speed at which the machine can work, we may mention that a skilled operator can test about 100 pieces of wire of No. 11 B.W.G. in an hour.

ENGINES OF THE SS. "STUTTGART."



WE illustrate on the opposite page and on page 60 the engines of the screw steamer "Stuttgart," built by the Fairfield Shipbuilding and Engineering Company, Limited, Glasgow, for the Norddeutscher Lloyd, Bremen. A similar set of engines are also being supplied to the ss. "Carlsruhe." The two sister ships are vessels of 5,200 tons each, and the indicated horse-power of the engines is 3,200. The engines are of the triple expansion type, the cylinders being 31in., 52in., and 83in. respectively, and the stroke 4ft. 6in. Link valve gear is employed. The high-pressure cylinder is fitted with a piston valve, and the intermediate and low-pressure cylinders with double-ported slide valves. There are two double-ended boilers for the main engines, each 14ft. 4in. in diameter and 17ft. long, and two single-ended boilers, each 14ft. 4in. in diameter and 9ft. 8in. long, for the auxiliary engines. The double-ended boilers are fitted with Fox's patent corrugated furnaces, and the latter with Messrs. John Brown & Co.'s ribbed furnaces. All the boilers are intended for a working pressure of 150lb. per square inch. The reversing engines are by Messrs. Brown Brothers, Edinburgh. Messrs. G. & J. Weir's feed-water heater, pumps, and evaporators are fitted in both vessels. The crank shaft, which is of steel, was made by Messrs. Vickers, Sons, & Co., Sheffield; and the thrust-and-tunnel shafts, which are also of steel, have been made by Messrs. John Brown & Co., Sheffield. The boss and blades of the propeller are also made of cast steel. At the trial trip of the ss. "Stuttgart," which took place on the 13th ult., the mean speed of a two hours' run was 13 knots per hour.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 57.)

PARIS, 14th January, 1890.

COAL.—The coal question is now almost the only one discussed in industrial circles. The interruption of the imports from Belgium, occasioned by the strike of the colliers, and heavy purchases of French coal on Belgian and German account, has brought about a scarcity that is beginning to be very seriously felt. English coal is being delivered at places where it was never before seen, but the supply is inadequate to the demand. The moment is a favourable one for the importers of English coal, and, judging from the activity of the agents of English producers, the opportunity is being turned to good account. The prices now offered are considerably above those current at the end of 1889.

IRON.—It is significant of the precarious character of the situation that in all contracts now entered into for the delivery of iron a clause is inserted to protect the manufacturers in case of the production being interrupted or seriously restricted by a failure in the coal supply. In the Meurthe-et-Moselle, the Haute-Marne, the Ardennes, and the Nord there are already a number of works compelled to stop two days in the week. In these circumstances manufacturers are by no means eager to accept fresh orders, and, as a consequence, the current of trade is checked. In other respects the market is in a satisfactory state, and the prospects for 1890 are fairly good. Makers of railway goods trucks are overwhelmed with work.

CANNON FOR FOG SIGNALLING.—In the lighthouse service trial is about to be made of artillery for signalling in foggy weather. The gun chosen for this purpose is very long, and is self-loading, being of the machine-gun type. It is capable of firing from 20 to 30 shots a minute. If the experiment succeeds, a system of sound signals will be established for communicating with vessels at sea.

ELECTRIC TRAMWAY AT CLERMONT-FERRAND.—An electric tramway has just been opened between Clermont-Ferrand and Royat, two towns 7 kilometres apart. The installation consists of a Farcot steam engine of 150 h.p. and a six-pole Thury dynamo of 300 volts and 350 amperes. A small 24 h.p. steam engine and dynamo is used to excite the larger dynamo and to supply the station with electric light. The current is supplied to the motors on the cars by means of an overhead wire, and the return current passes along the rail. The speed of the cars is 12 kilometres per hour.

THE VALUE OF THE OHM.—M. Wuilleumier, of Paris, has recently conducted a series of experiments, by M. Lippmann's method, to determine the true value of the ohm. He found that it was equal to the resistance of a column of mercury at 0° C., 1 square mm. cross section, and 106·27 centimetres high. This value differs by 1/5000th from the values adopted in 1881 and 1884.

BERLIN, January 13th, 1890.

COAL PRICES.—A comparison of the prices of Silesian on January 1st and December 31st, 1889, shows in a forcible manner the change which has taken place in the situation of the coal trade. The figures represent the prices in shillings per ton on trucks at the railway stations nearest the pits. First quality: Large, 6s. 4d.—8s. 4d.; round, 6s. 4d.– 8s. 4d.; nuts, 6s. 4d.—8s. 4d.; small, 3s. 8d.—6s. 2d.; slack, 3s. 4d.—5s. 8d. Seconds: Large, 5s. 6d.—7s. 8d.; round, 5s. 6d.—7s. 8d.; nuts, 5s. 6d.—7s. 8d.; small, 3s.—5s. 2d.; slack, 3s.—5s. 4d. Thirds: Large, 4s. 4d.—6s. 4d.; round, 4s.—6s.; nuts, 3s.—5s. Coke, 10s.—24s.

IRON.—At a meeting of Silesian ironmasters, held here on the 10th inst., it was resolved, after a long debate, to make no further advance in the price of iron for the present. The reason which weighed most in coming to this decision was the difficulty of meeting English competition with the high rates now current. In spite of the high protective duties, German manufacturers exported to Russia in the first eleven months of 1889, 25,067 tons of pig iron, and 48,906 tons of finished iron and steel, in the form of bars, angles, and plates. For the same time the exports of this form of finished produce to Italy amounted to 35,065 tons, The exports of German wire to Italy amounted to 11,034 tons.

ZINC IN 1889.—The year 1889 was a period of constantly increasing prosperity for the Upper Silesian zinc industry. Prices steadily advanced from the 1st of January till they reached, on December 31st, a level that has not been touched since 1873. The W. H. brand of spelter was quoted at the former date £18 12s., and at the latter £25, free on rails at Breslau. Godulla, which began the year at £16 14s., ended it at £23 13s. Many manufacturers have sold forward to the end of 1890. The number of works now running is 23. A considerable rise in the wages of zinc workers took place in the course of the year. The outlook for the near future is very encouraging.

ASPHALTE IN STREETS.—Some interesting trials of asphalte are being made in the streets of Berlin. The powdered material, instead of being merely stamped down by hand rammers in the usual way, is strongly compressed by a 24-ton roller. The roller reduces the thickness about 25 per cent., making a very compact and hard surface, which is expected to resist the wear and tear of the wheels much better than the less dense form commonly employed. It has been found necessary to use a somewhat bituminous powder, as otherwise the surface is apt to crack. In some streets, to avoid the offensive smell of the heated asphalte, the latter is being laid down in large plates after the manner of flag-stone paving.

VIENNA, 13th January, 1890.

COALS.—The activity in the Bohemian coal market continues. The wintry weather and the situation in Germany had an important influence, and prices increased this week for both native and imported coals. Cokes are in good request, and are now double the price of the last year's. In January, 1889, a ton of coke was 7fl., and now its price is 14fl. The position of the West Bohemian trade during the last month is illustrated by the quantities of coals forwarded by the two railroads crossing the territory. The Dux-Bodenbach and the Prague-Dux railways forwarded last December 320,120 tons of coals, 147,465 tons more than in the same month of the previous year.

IRON.—In the iron market no change is to be noted, nor is one expected for a long time. The animated situation is sustained by an abundance of new orders, and many works are not able to cope with the demand. The trade in refined iron is very brisk, in spite of the steady increase of the prices, which are already 20 per cent. higher than they were at the beginning of 1889. A large order for bridge constructions has been given by the Southern railway to the Alpine Montan Company. The iron work to be delivered will amount in value to 1,250,000fl.

ELECTRIC LIGHT AT BUDAPEST.—The whole city of Budapest is going to be lighted by electricity. The municipal authority of the Hungarian capital has asked the Budapest Gas Company to give an estimate as to the expenses of substituting electricity for gas. The gas company's contract will end on December 18th, 1891. In their answer they offered to decrease the price of gas; and their estimate fixes the price of 100 watt hours at 0·056fl., and according to it the yearly expenses for a whole-night glow lamp of 14 c.p. comes to 98·22fl., whilst a 14 c.p. gas lamp charge is only 39·61fl. Notwithstanding this difference, the municipality is negotiating with the gas company for the establishment of an electric central station. If these alterations are not made by December of next year, the municipal authorities will give the orders to another firm, for it has resolved, at all costs, to start electric illumination.—Ganz & Co., of Budapest, in common with the Westinghouse Company, are erecting an electric central station of 15,000 lamps at Venice.

THE AUSTRIAN SUGAR INDUSTRY.—It is now just twenty years since the Austrian sugar industry became recognised as an international trade. In 1869 the first exports were made to England, Holland, and Germany. During the whole of the existence of this trade there has never been so great a fluctuation in prices as there was last year, when the price of raw sugar rose from 17fl. in January to 35fl. in July, and again fell to 14fl. in December.

BRUSSELS, 14th January, 1890.

THE COAL MARKET.—The position of the coal market is becoming seriously complicated by the continued strikes. The scarcity of coal is bad enough on account of the great demands, but the intervention of the strikes really makes the prospect of things alarming. The miners evidently think that they have now an opportunity if they ever had one, and they are holding out for higher wages and fewer hours, so as to participate in the higher prices received for the coal. Instead of the men abating their demands, they are now actually increasing them, and they have now fixed for a 25 per cent. rise in wages and a maximum day's work of nine hours. A great number of works of various kinds have been obliged to cease work on account of the scarcity of fuel. The Administration of the State Railways have been asking for tenders for the delivery of thirty-two lots of small coal of 1,000 tons each to be sent to different railway centres. There were no tenders at all sent in for most of the lots, and those that did come in for the others were quite irregular, and not at all in compliance with the regulations. The absence of tenders is not alone caused by the state of the market, but by the absurd clauses in the regulations for tenders.

THE IRON MARKET.—Manufactured iron remains firm at a base price of 18fr. per 100 kilogs. and 22fr. for plates. These prices, although high, do not repay the manufacturer, on account of the more than proportionately advanced rates for coal and pig iron. The prices really ought to be at least 3fr. per 100 kilogs. higher if they are to be at all remunerative. The New Congo Railway have ordered 1,300 tons of steel rails from Belgian makers. Several iron and steel works have recently been turned into joint stock companies.

THE GLASS MARKET.—The glass trade has been turned upside down by the continuation of the coal strike. The prices remain firm. What coal can be obtained is at a ruinous price. The operatives are beginning to consider whether it is not time for them to clamour and strike for a 30 per cent. advance in their wages. Such action, however, would most likely end in a complete collapse of the glass trade.

DÜSSELDORF, 13th January, 1890.

ENGLISH AND WESTPHALIAN COAL AT HAMBURG.—The following statistical records show the growth of the trade in English coal at Hamburg in the last ten years, and the competition encountered from the development of the trade in Westphalian coal. The figures represent the imports in tons; those in parentheses relate to the Westphalian produce received:—In 1880, 1,025,550 (338,910); in 1881, 1,001,118 (452,650); in 1882, 1,013,334 (475,890); in 1883, 1,050,000 (513,420); in 1884, 1,025,500 (548,730); in 1885, 1,138,700 (536,510); in 1886, 1,210,000 (518,930); in 1887, 1,230,000 (548,500); in 1888, 1,365,000 (627,890); in 1889, 1,580,000 (716,780). It will be seen from these returns that the Westphalian trade has considerably more than doubled itself in the last ten years.

IRON.—The situation of the market for crude iron is one of great strength. The production of the blast furnaces in the Rhenish-Westphalian syndicate in the last month of 1889 amounted to 127,923 tons, against 110,362 tons in November. In the same month the stocks, already very small, of forge Thomas and Bessemer pig were reduced by 3,000 tons, a healthy sign at this period of the year. The following are the prices of some finished forms of iron and steel at the end of each month of 1889:—Bars, 127s. 6d., 130s. 6d., 130s. 6d., 133s., 133s., 140s., 140s., 142s. 6d., 147s. 6d., 150s., 165s., 190s.; joists, 125s., 125s., 125s., 128s., 127s. 6d., 127s. 6d., 127s. 6d., 127s. 6d., 127s. 6d., 135s., 140s., 150s.; boiler plates, 170s., 175s., 180s., 180s., 180s., 180s., 195s., 200s., 200s., 215s., 220s., 245s.; thin sheets, 155s., 155s., 155s., 160s., 160s., 165s., 175s., 185s., 188s., 200s., 215s., 255s; hoops, 126s., 127s. 6d., 130s., 140s. 145s., 145s., 145s., 155s., 160s., 167s. 6d., 187s. 6d., 200s.; rolled iron wire (wire nail quality), 112s., 123s., 120s, 120s., 120s., 120s., 120s., 130s., 140s., 145s., 160s., 180s.; steel rails, 125s., 130s., 128s., 128s., 125s., 130s., 130s., 135s., 140s., 150s., 155s., 165s.

LILLE, 14th January, 1890.

IRON.—All the ironmasters of this locality are now well supplied with orders for the next four months, and fresh work is coming to hand freely. Considerable reluctance is, however, manifested to book fresh orders on account of the precarious position of affairs due to the scarcity of coal. The want of fuel is fast becoming a grave question for the ironworks of the Maubeuge district. Many of them are running but three days a week. Everywhere the coke ovens are idle, on account of the failure of the supply of coal. The scarcity is in large part due to the strike in Belgium.

TEXTILE MANUFACTURES.—The state of the market for linen goods in the last month of 1889 gave rise to hopes of a sharp revival of trade after the middle of January, when the holidays and the stock-taking season came to an end. These hopes are, it seems, doomed to be disappointed, for the market is growing more languid. The delay in the looked-for revival is no doubt due in part to the influenza, but this cause is certainly overrated. The truth is, the situation is not so strong as it was believed to be. Business is growing brisk again in the Roubaix-Tourcoing woollen trade. Manufacturers have in hand novelties for 1890 likely to excite admiration and to have a successful run. Since the Exhibition in Paris the Roubaix trade has undergone considerable expansion.

FLAX AND YARNS.—The flax market is not yet wholly out of the influence of the holidays and the stock-taking season. The quantity of home-grown flax on offer is small, and buyers are few. For the latter fact the influenza is largely responsible. Prices, both for home-grown and Russian, remain unaltered. For tows the market is in favour of buyers. Business is quiet in yarns, and prices are a little weak. Jute yarns, however, are in brisk demand. The prospects of the jute market are highly encouraging.

AMSTERDAM, 13th January, 1890.

THE LABOUR QUESTION.—The Dutch Government has sent in its reply to the remarks made by the Grand Committee of the First Chamber of the States-General regarding the Government proposals to continue the State inquiry into the economic condition of the working classes in Holland preparatory to remedial legislation. The Government agrees to extend the scope of the Commission's labours. The Commission is not only to examine factory and workshop hands, but also handicraftsmen generally, the labourers on peat bogs, the crews on board ship, and the employés of railways and other modes of transport. The Commission will also inquire into the working of insurance and pension funds for artisans. But there is no need to fix an elaborate programme beforehand; it can be settled gradually, as time goes on; and the Minister of Justice will have the power to instruct the Commission to proceed with one part of its task and then with another, after having consulted it thereon. In case of need, the Government will prepare new Bills conferring fresh powers upon the State Commission. The nature of the remedial legislation cannot now be indicated; much must necessarily depend upon the results of the Commission's labours. Nor is it possible to say for certain that there will be remedial legislation; but this doubt must not prevent an inquiry. Many evils cannot be remedied by legislation, but that is no reason to leave them unprobed, as an inquiry alone will convince numerous people that there is no remedy who now

Digitized by Google

continually press for it. The Ministers consider the present laws to protect workmen willing to work against the molestation of strikers as amply sufficient.

THE WEST INDIAN MAIL SERVICE.—The Royal Mail Service has undergone a complete change as from January 1st. The steamers will leave Amsterdam for Curaçoa and Surinam every third Thursday of the month (commencing the 16th inst.), and from Surinam and Curaçoa for Amsterdam the third Saturday of every month (commencing March 22nd). The monthly service between New York and Curaçoa will also be altered into a three-weekly one, commencing March 8th. The West Indian Mail Steamship Company has just added a fine vessel to its fleet in the "Prins Willem III.," built at Feienoord for this company by the Netherland Steamboat Company, between January and November last year. It is a steel-built screw-steamer, 264ft. long, 36ft. broad, and 23ft. beam, with triple expansion engines of 1,250 i.h.p. She is supposed to run 13 knots an hour, and this rate was exceeded on the trial trip. The vessel is fitted out most luxuriously, regardless of expense, and appears to offer all comforts to first and second class mail passengers. She is described as A1 at Lloyd's and Veritas. The Netherland Steamboat Company, which has a large shipbuilding yard at Rotterdam, has likewise in hand two great steamers for the Indian Mail Service, the "Carpenter" and the "Van Diemen," both to be ready by the middle of July. The yard now employs 1,400 hands, and it is the largest establishment of its kind in Holland.

NEW DUTCH WAR VESSELS.—The expenses of the Dutch Navy Budget in 1890 will nearly reach £1,200,000. Two new ironclads of large dimensions are to be added to the war fleet, and they are now building. Messrs. Jarrow also have an order for another torpedo boat and a torpedo chaser, one of six ordered. These chasers run a minimum speed of 20 knots an hour, and each is armed with Hotchkiss quick-firing guns 1⅛in. and 3in., besides submarine torpedo tubes.

THE TRANSVAAL EXHIBITION AT AMSTERDAM.—This Exhibition has been opened in the gardens of the Crystal Palace, and proves a great success. The building is the same that stood in the Paris Universal Exhibition grounds, near the Seine, and is filled with products from the South African Republic, principally agricultural, but samples from the gold, silver, tin, copper, lead, manganese, and coal mines also take up much room. There are likewise ostrich feathers, different kinds of wood, elephant tusks, hides, fruits, &c., the whole giving a complete idea how varied and rich the Transvaal products are. The opening ceremony was attended by many officials, Dutch and South African, and numerous speeches testified to the importance of this Exhibition, and to the cordial feeling between the young republic and the old mother country.

COPENHAGEN, 11TH JANUARY, 1890.

THE SWEDISH NORWEGIAN RAILWAY COMPANY.—Considerable light has been thrown upon the history of this large, but so far unfortunate, undertaking by a volume of more than two hundred pages, published by the Swedish Civil Department. It appears that the original calculation of the promoters for the Lulea-Gellivara section was deemed much too low by the Swedish officials, who raised the sum that should serve as a basis from 4,236,177kr., 218,359kr. per Swedish mile (about 11 kilometres), to 7,300,000kr., or 376,288kr. per Swedish mile. On July 10th, 1884, the company gave notice that work had been commenced on the Lulea-Gellivara section of the line. The company appears often to have both applied for facilities in the terms of the concession as regards technical points, and also to have experienced considerable difficulty in carrying out the obligations incumbent upon it. As early as March 27th, 1885, the Swedish Government refused an application about alterations as to gradients, &c., and on December 2nd, 1887, the first application for prolongation of time was granted to a small extent. Also for the section between Gellivara and Luossovara, the Swedish Government found the company's estimated cost of 3,250,000kr. too low, and raised it to 4,019,990kr. On June 8th, 1888, the Swedish Government gave the company permission to commence work on the Gellivara-Luossovara section, although they did not consider that the company had complied with the terms of the concession as to having the necessary capital at its disposal. The Government's reason for granting this permission was consideration towards the many hands that would be thrown out of employment if permission were not given. This permission was, however, withdrawn on June 29th, the Government having learnt that the company in the meantime had dismissed a lot of men. On July 13th, renewed permission was, however, granted. On December 31st, 1888, the Government very promptly declined the company's one-sided offer to the Swedish State of the whole undertaking. In January, 1889, complaints were made about the company not replacing the undersized sleepers, and altogether as to the condition of the line, which, it appears, was built in a comparatively short time, so that the ore traffic could be commenced, but had not been kept in proper repair. The company was therefore requested to put the line in order as early as weather would allow of it. On July 26th the Government prohibited all traffic on the line, except conveyance of labourers and railway officials, &c., and on August 16th refused an application from the company about facilities as to monetary deposits for workmen, and on September 5th an application for permission to resume ore traffic had the same fate.

PAPER MANUFACTURE.—Another large paper mill company has just been formed in Sweden by the Klippau paper mill in Skane being transformed into a company for the purpose of extending their business. The manufacture will comprise paper, wood pulp, and starch. The capital will be about 2,000,000kr.

MATCH FACTORIES.—Fifty men from the Iönköping Match Manufactory are at present attending a slöjd school in Iönköping at their employers' expense. They are attending a course of what is called "pedagogical slöjd," and this is probably the first instance of labourers receiving such instruction. The Iönköping match manufactory is doing a great deal for their labourers, and trying to make things as pleasant for them as possible.

MADRID, 13TH JANUARY, 1890.

BILBAO PORT IMPROVEMENTS.—The improvements at the entrance of the port of Bilbao are being vigorously proceeded with, and both the authorities and the public in general are showing themselves well satisfied with the proceedings of the contractors.

LARGE RAILWAY DIVIDEND.—The directors of the railway from Bilbao to Durango (one metre gauge) have paid a dividend of 14 per cent. on the share capital of the company. It is supposed that this will be the final settlement of the year, and that any excess will be passed to the reserve fund. The shares are quoted at 250 per cent. premium.

ASTURIAN COAL.—Coal miners in Asturias are now actively preparing to increase their business in view of the high prices of coals prevailing in Europe. Another company, that of Messrs. Herreros, are about to acquire a steamer for their coal trade, and there is no question as to this being only a beginning of a very large fleet. The first step is to be the opening of the port of Aviles, after the works in progress are finished.

ELECTRIC LIGHT AT CADIZ.—On the 28th ult. the Cadiz Corporation signed a contract with Senor de la Viesca to light the public thoroughfares of the town with 1,000 incandescent electric lights of 16 candle-power. The condition is that each light will be used, on an average, seven hours per day.

ELECTRICAL ENGINEERS' ACADEMY.—As a sign of how strangely official things are dealt with here, the Minister of the Colonies is feeling the want of electrical engineers, and is therefore going to create an establishment for electrical teaching.

RESIGNATION OF THE MINISTER OF MARINE.—The Minister of Marine, Senor Rodriguez Arias, to whom the country owes a great deal, has resigned, as he is annoyed and discouraged by some criticisms in connection with some boats built by Messrs. Otero Gil & Co. The honesty and high character of the resigning Minister is acknowledged by everyone, and it would have been most unjust to ruin the house by refusing the boats when the fault was only imputable to the official naval architects.

MADRID GAS WORKS.—This company has made an experiment by issuing a quantity of debentures bearing 4 per cent. interest with a view of paying out their 5 per cent. ones, thus saving a considerable sum in interest paid. It is reported, however, that the public has not answered as they expected, and that the apparent subscription has been mostly covered by the shareholders themselves. The scheme has, therefore, been an utter failure.

NEW YORK, 4TH JANUARY, 1890.

THE COAL MARKET.—There is little change in the anthracite market. There is hardly any demand, and many of the collieries have closed down to half or three-quarter time. The past year, though considerably less prosperous than 1888, has a large amount of business to its credit. The total shipments have been only about 8 per cent. less than last year. Prices are low, however, some of the larger dealers selling at 25c. below circular rates, and allowing commission in addition. The consumption for steam and furnace purposes continues fair, but there is nothing doing in any other lines. Bituminous coal is scarce, owing to the difficulty of procuring transportation and prices are high in consequence.

THE IRON AND STEEL TRADE.—The past week or so has been nearly all holiday, so that there has been very little business done. What little has been done shows such a strong market that prices are very likely to be higher on the renewal of business. In pig iron, as all the larger consumers have placed their immediate orders, it is not likely that there will be much done for some time. There is not much disposition to place orders of any size at current rates. Plenty of buyers could be found at prices ruling a month ago, but there is no great disposition to take large lots at $20, $19, and $18 per ton, the present price at tide for the leading grades. In manufactured iron prices are nominally the same as last week, but a little more money would have to be paid to secure anything like good-sized lots. Sellers are in considerable doubt as to what the market will stand for deliveries a short distance ahead. Steel is decidedly dearer, and although iron is very firm the advancing tendency is less marked than in steel. Prices are from 1·95c. to 2c. per pound for best refined bars, 2·30c. to 2·35c. for plates and angles, and from ¼c. to 3·10c. more per pound for steel. Steel rails are firmly held at $35 per ton at mill. The demand has slackened off somewhat, but makers are satisfied with the market, and that prices will go still higher. Large sales of billets have been made at from $36 to $37 per ton at the mills, but higher prices are asked for increased amounts.

THE METAL MARKETS.—There has been an increased demand for copper, and prices are stronger in consequence. Lake is quoted at 14¼c. per pound, and other grades in proportion. The tin market is declining, with considerable speculative dealing. There is nothing doing in plates. The lead market has been quiet, with prices a little weaker. Sales have been made at from 3·85c. to 3·90c. per pound. The demand for spelter is strong, but shows signs of falling off. Prices are firm. Antimony is fluctuating considerably, average prices asked being about 20c. for Hallet and 28c. for Cookson.

THE CANADIAN RAILROADS.—The transhipment of goods in bond through the United States, on Canadian railroads, without payment of duty, is now done under Treasury regulations. This has enabled the Treasury officials to control this important matter, and to meet any movement antagonistic to the commerce of this country by the Canadian roads. These roads are anxious to get a Bill through Congress to take this power out of the hands of the Secretary of the Treasury, and are anxious to have a law passed similar to one introduced in the Senate a few days ago, which gives every road the right to tranship goods through the United States in bond, or to take them from one part of the United States to another through Canada without payment of duty. The matter promises to be of considerable prominence in this Congress.

BRUSH PATENTS.—The long-pending litigation relative to the infringement of the Brush electric light patents was brought to an end in the Federal Court by decision against the Jenney Electric Light Company. Judge Gresham, who heard the arguments over a year ago, and has since had the matter under advisement, decided that the Jenney Company had infringed the double-carbon burner invented and patented by Brush, and ordered an entry permanently enjoining it from continuing the manufacture of the burner. The decision will be very important in effect, and will probably have some influence upon many other infringement suits pending in different parts of the country.

BURNING OF AN ELECTRIC LIGHTING STATION.—The first central station for incandescent electric lighting, established by the Edison Illuminating Company, at 255-7, Pearl Street, New York City, in 1882, was burned out by a fire which started at about six o'clock a.m. on the 2nd inst. About 18,000 incandescent lamps were supplied from it in the lower part of the city, many buildings being entirely dependent upon electric illumination, while others were also supplied with gas. The machinery consisted of eight old style "Jumbo" dynamos, with the necessary boilers and engines. The cellar and basement were very much crowded, and the full capacity of the station was reached some time ago. The building was old and not fireproof. Had the station been constructed especially for the purpose, probably such an accident would have been provided against. The current was distributed by the Edison underground system, and it is supposed that through leakage one of the dynamos was short circuited and burned out, igniting the oil-soaked floor, and leading to such an immediate spreading of the flames that the station facilities for fire extinguishment could not be utilised. The public fire department was summoned at once, one fire engine being available immediately around the corner. The elevated railroad runs through Pearl Street, and it was necessary to suspend traffic for several hours, the firemen using the structure to good advantage, from which their streams could be brought effectively to bear upon the flames. Three hours elapsed before the fire was brought under control, and meanwhile new machinery was ordered from Schenectady, about 150 miles distant. An auxiliary station on Liberty Street, half a mile away, was also connected to the system, from which about 5,000 lamps are being supplied temporarily. The loss is given as 200,000 dols., upon which there was 125,000 dols. insurance. The fire occurred at a very unfortunate time, when so much stress had been laid upon the safety of the low tension system, as, amidst the clamour regarding the loss of life from high tension currents, the question of fire risk had been scarcely alluded to.

CHICAGO'S CANAL SCHEME.—Last week an election was held in Chicago, at which nine drainage trustees were chosen. Their duties are to supervise the construction of a canal connecting the waters of Lake Michigan and the Illinois River, which empties into the Mississippi, for the purpose of carrying off the sewage of the city in that direction, instead of emptying it into the lake. The canal, as proposed, will have sufficient dimension to admit of the passage through it of large lake vessels, and thus furnish a commercial outlet to the Gulf of Mexico. This is of course something of a menace to the railroads running south and west from Chicago, and a statement is made that a combination of these interests has been formed for the purpose of securing the contract for the work in order to defeat the commercial feature of it and make it merely a drainage canal.

ALASKA FISHERIES.—As stated in my last letter, the Secretary of the Treasury has invited proposals for the privilege of taking fur seals on the islands of St. Paul and St. George, Alaska. Bids will be opened on the 23rd inst. for the exclusive rights of the fisheries for twenty years from May the 1st, 1890. One requirement of the contract is that the successful bidder will have to provide a public school building on each island, and pay the expenses of keeping them up for not less than eight months; also to pay the inhabitants whatever just compensation the Secretary may prescribe for their labour. The number of seals to be killed for their skins the first year is limited to 60,000, and the Secretary will fix the numbers for the succeeding years.

COMPARISON OF COST BETWEEN GAS AND ELECTRICITY.

THE ILLUMINATING POWER AND PRICE OF GAS PER 1,000 CUBIC FEET AS SUPPLIED IN LONDON, MANCHESTER, AND ABERDEEN.

					Equivalent light in candles for one hour.	Comparative cost.	Ratio of cost, showing the number of times cheaper gas is than electricity.
ELECTRICITY.	One incandescent lamp of 16 candle-power requires 60 watts per hour, or 60 Board of Trade units every 1,000 hours, which at 8d. per unit (the price now charged by the House to House Electric Supply Co., Kensington, and the Electric Supply Co., Liverpool) amounts to 40s. 0d. To which must be added the cost of lamp, 3s. 9d.				16,000	s. d. 43 9	1
WITH ORDINARY GAS BURNERS.	Quality of gas.	No. of cubic feet required to produce 16 candle-power per hour.	No. of cubic feet required for 1,000 hours.	Price of gas.

THE MANCHESTER ASSOCIATION OF ENGINEERS.

MR. JOHN WEST, M.Inst.C.E., gave his presidential address before the above association on the 11th inst. After referring to one or two local matters, Mr. West went on to consider the relative merits of electric and gas lighting. There were electric lighting companies formed for lighting London, with a united capital of over three millions sterling, and these companies were now erecting buildings, and putting down steam boilers, engines, electrical plant, and mains for supplying the various districts. Electricity was supplied by the various companies on the following different systems, viz.:—(1) The direct continuous current; (2) the direct continuous current storage system; and (3) the alternate current transformer system. The relative merits of the various systems were stated, after which Mr. West went on to deal with the question of the cost of the supply.

The charges for electricity ranged from 7d. to 8d. per Board of Trade unit of 1,000 watts, and some companies would not give a supply to a consumer under a minimum charge of £14 per annum. While it was admitted that electricians have made some progress in perfecting machinery for securing a better and more regular supply of electricity, it must not be forgotten that improved lighting by gas has also made very rapid strides. Having in 1882 dealt with the question of defective burners he pointed out that since that period two new systems of burners have been perfected. These were the regenerative burners of Siemens, Sugg, Wenham, Fourness, and others, and the incandescent burners of Welsbach, Clamond, and others, both these types having come into general use, particularly the regenerative kind, and from them a better light can be obtained with from half to one-third the quantity of gas. He had been favoured with the results of some experiments made by Mr. Alexander Smith, of Aberdeen, with regenerator burners of suitable size for lighting halls, shops, and large rooms, as follows:—

By consuming 10 cubic feet of gas per hour in one of these lamps a light equal to 155·2 candles was obtained, or 15·52 candles for each cubic foot of gas consumed per hour. This result was obtained with gas, which, when tested according to the method prescribed in the Gas Works Clauses Act, gives a light equal to 5·6 candles for each cubic foot, thus showing a gain of 9·92 candles for every foot of gas per hour when used by these lamps, or a gain of over 177 per cent.

Similar tests had been made with London gas, and with the Wenham and other regenerative lamps, which showed similar satisfactory results. A photometric test of the Welsbach lamp made by Professor Carlton J. Lambert showed that an illuminating power of 28·8 candles was obtained with a consumption of 3 cubic feet per hour of London 18-candle gas. The relative cost of gas and electricity with equal light from each was then compared. Eminent electricians stated that a 16 candle-power incandescent lamp was calculated to last about 1,000 hours, and would absorb 60 Board of Trade units of electricity in that time. The cost of 60 units at 8d. per unit, the usual Board of Trade limit of charge, would be 40s., to which must be added 3s. 9d., the cost of the lamp, which made a total of 43s. 9d. per 60 units. To make the comparison clear as to the cost of gas in London, Manchester, and Aberdeen to produce the same amount of light, both with ordinary burners and regenerator burners, Mr. West prepared the above table.

The comparison is made with the best type of burners, as these are in the reach of every one, and the gas is compared with an electric lamp which is assumed to give the same light throughout the 1,000 hours, but such is not the case, as it is found, after they have been used for a time, that the carbon filaments get volatilised and deposited on the glass, consequently the size of the filament is diminished and the surface of illumination reduced; the resistance of the filament would also be increased and the intensity of the incandescence decreased for a given power; the carbon on the glass further reducing the light. These facts are confirmed by the experiments of Mr. W. H. Preece, Chief Electrician to the Post Office, who states that the ordinary commercial lamps consuming 3·54 watts per candle-power when new, require 6·1 watts per candle-power after burning 900 hours, the mean absorption being 5·25 per lamp. Stated the other way, it appears that the candle-power of the lamps after burning 900 hours is only 58·5 per cent. of the initial duty, and the mean value of a lamp during its life is only 67 per cent. of that which it possesses when new. Assuming an average use of four hours per day for a lamp, this means not only that all incandescent lamps must be renewed before 225 days, when their luminosity is little more than half what it was when new; but taking all the lamps in an establishment together, three should be provided to do the work of two if the intended average lighting effect is to be maintained. The advantage of electric lighting in a low-pitched room where ventilation is defective was admitted, but this could be obtained with regenerative burners. Mr. West then went on to give his views as to the cheapest and best way of producing and delivering electricity to the consumer under varying circumstances. He was informed that in one town a complete electric lighting plant driven by steam power and supplying from a central station 3,000 incandescent lamps of 16 candle-power, with cables laid along the streets, would cost about £20,000. Mr. Ferguson Bell, of Stafford, stated that in their town it would cost £14,500 for a like installation, but he did not include the cost of land in his estimate, details of which were given.

If the number of lights was sufficient, there was the plan of a consumer providing himself with electric light by means of a complete plant, driven either by a gas engine or steam engine, on his own premises. A friend of his had given him the cost of a complete electric installation, including fittings for 320 incandescent lamps of 16 candle-power each, which had been working for about two years at one of the banks in London, and was driven by Crossley Bros.' gas engines. The plant included two 9 horse-power Otto engines, two dynamos, and two sets of accumulators, and cost £3,000. The working expenses—for 1,800 hours per annum, the building being dark—were, including interest on capital at 10 per cent., £1,012 10s. per annum. The current supplied was equal to about 38,500 Board of Trade units. The analysis of the above figures shows that—

	d.	
The cost for generating electricity, including wear and tear and interest on capital, is.....	5·58	per Board of Trade unit.
Interest on fittings	·56	„ „
Cost for renewal of lamps	·7	„ „
The total cost per Board of Trade unit on the complete installation	6·84	„ „

From these figures it will be seen that if the bank had obtained electricity from a central station electric lighting company, at 8d. per unit, the total cost to them would have been:—

	d.	
Electricity	8·0	per Board of Trade unit.
Interest on fittings	·56	„ „
Cost for renewal of lamps	·7	„ „
Total.....	9·26	„ „

So that by generating electricity on their own premises they saved 2·42d. per unit, or £357 19s. 2d. per annum. He thought it would be found in practice that the most economical and satisfactory way of producing and supplying electricity to the consumers would be by gas engines on their own premises, or by a system of very small central stations, where a few houses or shops were in close proximity and worked by the direct system of distribution. By this plan we would avoid expensive outlay on buildings, at the same time be advantageously using the existing gas mains, besides being able to dispense with the cost and maintenance of an electrical meter on the premises. The cost of generating plant for 400 incandescent 16 c.p. lamps on this plan would be as follows: Plant, £900; working expenses for 1,800 hours per annum, £660; current supplied, 43,200 Board of Trade units; cost per unit, 3·66d. In the case of an installation of 50 lamps of the same power, the cost of plant would be £275; the working expenses, £110 19s.; the current, 5,400 units; and the cost per unit, 4·93d.

By this plan electricity could be supplied, as shown by these examples, at prices varying from 3·66d. to 4·93d. per Board of Trade unit, according to the size of the installation, inclusive of working expenses, repairs, depreciation, and interest on capital. The usual charge by the London electrical companies, whose supply was generated for large districts in large stations driven by steam power, was 8d. per unit, showing a saving of 4·34d. and 3·07d. per unit respectively in favour of the gas engine scheme. To explain how the charge for working by gas was obtained, he took first the quantity of gas required per indicated horse-power per hour at 20 cubic feet; with this amount of gas a maximum of 8 lamps of 16 candle-power each could be maintained per hour, and by allowing a little extra for irregularities, and taking 50 cubic feet of gas to produce one Board of Trade unit, the gas would cost 1½d., to which must be added the other figures in the table of working expenses just given. The reason why electricity could be distributed to customers by gas engines cheaper than from a large central station, was because the very expensive cables for distributing the electricity (which in most cases take one-third of the capital employed) could be dispensed with, and the further expenses for renewal after they have been in use for a time. It was stated that Edison's cables in Berlin only lasted three years. These cables cost £90,000 for 36,000 lamps of 16 candle-power and 144 arc lamps. From these facts it was quite clear that the interest on the first cost and maintenance and renewals of distributing plant alone would be more than the cost of gas delivered on the consumers' premises from the existing mains. While approving of the action of the Corporation of Manchester in applying for a provisional order, he thought they should not put down a central station, but rather encourage separate installations in which gas engines would be used, Messrs. Crossley Brothers having sold 550 for this purpose. Gas engines and dynamos might be hired to consumers in the same way as stoves are. In many cases where arc lights of high power were employed on out-door work they had been superseded by the "Lucigen" and "Wells" patent portable lights, the latter being supplied with Wells oil or refined gas tar. This was a very cheap and useful light, 250 of them being in use on the Ship Canal. It must not be forgotten that in nearly all cases both gas and

Digitized by Google

electric light were obtained from the energy contained in coal, and that gas companies and corporations who own gas works could produce as much light direct from the gas made from a ton of coal (if properly applied) as could be obtained from a ton of coal by any other means, besides having the resulting coke, tar, and ammoniacal liquor to dispose of. So, as far as he could judge, gas must remain by far the more economical of the two methods of lighting.

Dealing with the subject of "water gas," he said it had been brought very prominently before the public during the last year or two, more for the purpose of floating speculative companies, perhaps, than because of any real novelty; for at least thirty years had elapsed since it was new to English gas engineers, and many had been the trials of variations of the same principle, owing to the extreme simplicity of the apparatus and the large amount of work that could be done on a small area of land; but the question of ultimate economy had often prevented the success of schemes which otherwise were satisfactory. At the present moment he was referring more particularly to the use of water gas for general lighting purposes, as there were many examples in England of its admirable qualities as a heating agent for certain processes.

Mr. West then gave a brief description of the various methods of manufacturing water gas, and said that one great drawback to the process was the time spent in producing the necessary heat, and the large volume of producer gas of very poor quality thereby generated. In America, where the water gas system had reached its highest development, the gas was often produced from generators upon a large scale on the same works as ordinary coal gas. In some places in England, where water gas was used for heating the producer gas was a great nuisance and source of loss. There was a great difference between the circumstances of the production of water gas as a lighting agent in America, and its production here; for in America the petroleum oil used to invest the gas with lighting properties was easily obtained at a very low price, and the price of coal gas was much higher than in England, so there was a greater margin between the two kinds than was the case here. As a heating agent water gas was very valuable where a very high flame-temperature was desirable, as the theoretical temperature was about 5,000° F., while that of coal gas was about 2,500° F. In conclusion Mr. West said that many ways had been tried to obtain illumination from water gas, but he thought it questionable whether there were any advantages to be gained. The comparisons instituted had been founded on actual experiment and experience, and in this way only was the truth to be arrived at.

Notices of Meetings.

"	English Ingots	99 10 0	"	.....

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: There has been an irregular market in raw copper during the past week, owing to realisations on the part of certain speculators and the high rate of discount now ruling. Chili bars are consequently lower, quotations to-day being £50 5s. to £50 10s. cash. Manufactured copper still remains at £66 to £69, sheets and bottoms.

TIN weaker, with limited business doing at declining prices.

LEAD is quiet again, and rather lower in price on the week.

SPELTER keeps very firm, and higher prices are looked for.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—The firmness noted in our last is fully maintained. Bleaching powder is again a shade better, and the higher qualities of caustic soda have secured a further good advance. This is caused by short supply, some of the manufacturers having had difficulty in obtaining supplies of slack. Chlorate of potash is steady, at 4¾d. There has during this month been a good demand for oxalic acid at the reduced prices, consumers having delayed purchasing in order to take advantage of the fall. Acetates of lime are very firm. Acetates of lead are steady, but nitrate of lead is rather easier. Sulphate of copper is almost unobtainable for prompt delivery.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, Jan. 16.—*Iron.*—Prices of bars and joists oscillate between 168s. and 176s. a ton here in Paris, where business is not brisk. In the provinces the markets are very firm. In the Nord bars are quoted 156s. The demand continues strong generally, but sellers are cautious, fearing further difficulties from the short supply of coal. Production is greatly restricted from this cause already.

BERLIN, Jan. 16.—*Bourse.*—The market for industrial securities is growing stronger again. Shares in collieries are quoted higher. The firmer tone generally prevailing indicates greater confidence in the industrial situation.

Metals.—The metal market is growing more active, and the weakness in prices observable a week ago has given place to a firm tendency. Mansfeld refined copper is steady at £61 to £62 10s. Best English brands, £61. Banca tin is quoted £107 10s. There is a brisk demand for spelter. The W. H. brand is quoted £27 10s.; other Silesian sorts, £26 15s. Lead is a little weak. Antimony regulus firmer.

Flax and Yarns.—In the Trautenau market business is again active. Buyers of flax are operating largely at the prices current a week ago. The demand for yarns is fairly brisk, the tendency of the market being in favour of sellers.

BRESLAU, Jan. 16.—*Coal.*—The scarcity of coal increases, and as the merchants control two-thirds of the output the industrial situation is becoming precarious. Polish coal is for the first time being imported into Silesia. A few sample truckloads of small have arrived here. The price varies from 5s. 3d. to 5s. 10d. on rails at Sosnowice. The labour market is assuming a less threatening aspect.

Iron.—The market is animated and buoyant, the demand for pig being very strong. Forge pig is dearer. A good deal of foreign pig is now being delivered here. A brisk trade is being done in finished iron and steel. Bars are selling a little above the official quotations. Common plates are selling freely at 240s., and thin sheets have been largely dealt in at 250s. a ton. Founders are very busy. Many have their order-books full for the next four months.

Zinc.—The market for zinc continues very active at last week's prices. The W.H. brand of spelter sells readily at £25. The zinc merchants are offering zinc dust at 85 per cent. of current zinc prices. Most works have sold the whole of their produce six months forward. The market is firmer for forward delivery.

DÜSSELDORF, Jan. 16.—*Iron.*—Large buying orders for spiegel pig are coming to hand from Belgium. The price for the 10 to 12 per cent. quality is very firm at 102s. Forge pig continues in brisk demand at 92s. Thomas pig at 82s. shows an upward tendency. Bars are in good demand for export. Angles are a little higher in price; latest price, 210s. Hoops, too, are a little dearer, 210s. having been paid. Rolled wire remains relatively low at 180s. According to a rumour current here, the wire syndicate is to be re-established.

HAMBURG, Jan. 16.—*Nitrates.*—The market is dull for Chili saltpetre. Spot goods are offered as low as £8 3s. For cargoes to arrive at the end of February or the beginning of March the price asked is from £8 5s. to £8 5s. 6d. a ton.

BRUSSELS, Jan. 16.—*Mining Legislation.*—The Federation of Belgian Miners have agreed with M. Paul Janson, the Deputy for Brussels, on the terms of a new Bill regulating the employment of labour in mines, to be laid before the House of Representatives on Monday next.

WE have received a copy of the "*Mechanical World* Pocket Diary and Year Book for 1890." In addition to the usual useful information contained in this yearly, there is some further information on triple expansion engines, casting, standard fittings, &c., together with an account of some more recent improvements in various branches of mechanical practice.

HOME INDUSTRIES.

LONDON 16th January, 1890.

The Money Market.—The money market retains its firm tone, and while, from some points of view, the dearness of money is inconvenient, the maintenance of high rates is desirable for some time yet for the general security of the monetary position. The near approach to a money crisis at the close of the year was due to the fact that the previous efforts to avoid a too great weakening of the position of the Bank of England had not been sustained. Occasional attempts to protect the Reserve had been made, but so soon as the momentary danger passed, things were allowed to take their course, and at last got out of control. The outside market has now backed up the action of the Bank, and at the expense of a little inconvenience the money market bids fair to assume a more stable aspect. One unpleasant side of the picture has been seen this week on the Stock Exchange, where loans for carrying forward transactions into the new account have been charged for heavily. This has checked new speculative business, but a fair amount has been transacted. Consols have improved with the more settled feeling in the money market. Among home railway stocks those of the goods lines have shown little animation, the inclination being to wait for the dividend announcements. The Manchester, Sheffield, and Lincolnshire dividend was unexpectedly good, and the securities of that line had a rapid rise, part of which has since been lost owing to sales to realise profits. It was the same with the Brighton Railway stocks. American railways have been dull and rather out of favour, but Canadian Pacifics are in request. The decline in Mexican (Vera Cruz) rails continues, the traffic returns remaining obstinately bad. The movements in foreign stocks have tended upwards. Brazilians have recovered a little. Peruvians have improved on the signing of the grace contract, and Spanish are still sought for. Nitrate shares are still a falling market, and copper securities have weakened in sympathy with the price of the metal.

Companies.—The following companies have been registered since our last report:—The Government Guaranteed Railways and General Syndicate, Ld., with a capital of £10,000; John Anderson & Co., Ld., with a capital of £3,000, to carry on the business of sawmill engineers; The Honduras Corporation, Ld., with a capital of £62,500, to acquire mining rights, &c., in Honduras; The Leeds and Wakefield Breweries, Ld., with a capital of £200,000; The West Australian Exploration Company, Ld., with a capital of £20,000, to acquire mining rights &c.; The Sambas Exploration Company, Ld., with a capital of £300,000; The Transvaal Minerals, Ld., with a capital of £200,000, to carry on the smelting of iron ore acquire mining rights, &c.; The English and Continental Shipping Company, Ld., with a capital of £27,000; William Johnston & Co., Ld., with a capital of £250,000, to carry on the business of ship owners, &c.; The Syndicate of Electrical Engineers, Ld., with a capital of £10,000, to establish institutions for testing electric instruments, &c., for profit; The Sanitation Company, Ld., with a capital of £10,000, to carry on the business of sanitary engineers; Klerksdorp Elandslaagte, Ld., with a capital of £125,000, to acquire certain mining claims in South Africa; The Inventors' Bureau, Ld., with a capital of £5,000; The Great Western Colliery Company, Ld., with a capital of £300,000; The Midland Coal, Coke, and Iron Company, Ld., with a capital of £375,000, to acquire and work certain collieries, &c., in Staffordshire; The Automatic Fire Check Company, Ld., with a capital of £5,000, to carry on the business of manufacturers of fire checks; Richard Thompson & Co., Ld., with a capital of £2,100, to carry on the business of weaving and cotton cloths manufacturing; Bailey, Watson, & Berry, with a capital of £2,000, to carry on business as cotton and worsted spinners; Caylloma Silver Mining Company, Ld., with £250,000; The Cravenette Company, Ld., with a capital of £30,000, to carry on the business of waterproofers of cloths; The Grand Canyon Mining Company of Arizona, U.S.A., Ld., with a capital of £75,000; The Railway Supplies Company, Ld., with a capital of £25,000, to carry on the business of makers and dealers in all kinds of railway appliances; Healy Bros., Ld., with a capital of £30,000, to acquire the business of rope and twine manufacturers; The Peruvian Exploration Syndicate, Ld., with a capital of £20,000, to explore mines and grounds in Peru.

The Board of Trade Returns.—The returns for the month of December and for the whole of the past year are very satisfactory. The month's imports amount to £38,267,934, as compared with £37,940,625 in December, 1888, being an increase of £327,309, or 0·9 per cent. The exports were £20,903,353, as compared with £18,814,209 in December, 1888, being an increase of £2,089,144, or 11·1 per cent. This is a very marked advance in the latter case, and shows that the export trade is in a most satisfactory progressive condition. Higher prices are also being obtained, for the month's exports of iron and steel are valued at £2,508,030, an increase of 21·5 per cent., whereas the quantity only advanced by about 6 per cent. Nearly all the items show an advance. Machinery and millwork have risen from £1,101,988 to £1,325,675, or 20·3 per cent.; chemicals have increased by nearly 9 per cent.; coke, coal, and fuel, 21 per cent.; and copper, 128 per cent. Cotton piece goods have fallen off, but only infinitesimally. The year's exports were £248,091,959, as compared with £233,842,607 in 1888, being an increase of £14,249,352, or 6·1 per cent. The imports for the year amounted to £427,210,830, as compared with £386,582,026 in 1888, being an increase of £40,628,804, or 10·5 per cent. The exports of metals and articles made therefrom (with the exception of machinery) increased by £3,790,154; machinery and millwork, by £2,315,391; and chemicals, by £497,448. It is clear that 1889 has left little to complain of in the matter of foreign trade.

The Navy.—The new composite gun-vessel "Thrush" left Sheerness on Saturday for the official trials of her machinery, which took place in the North Sea, under the superintendence of the officials of the Medway Steam Reserve. The trial was of eight hours' duration, and was of a most satisfactory character, there being a total absence of hot engine-bearings or priming of the boilers. The engines developed 804·5 h.p., which was 84·5 h.p. in excess of that contracted for. The "Sparrow," sister ship to the "Thrush," also underwent her natural draught trial in the North Sea, with equally successful results. With a mean of 121lb. of steam in the boilers, the engines worked at 157·7 revolutions per minute, and developed 803·9 h.p.

Civil and Mechanical Engineers' Society.—On the 8th inst., at a meeting of this society, a paper, entitled "Notes on Labour and Prices in India," was read by Mr. H. H. Parkinson, A.M.I.C.E., late assistant chief engineer to H.H. the Gaekwar of Baroda. During the lecture the author said that the wages of the Indian labourer were only one-tenth of those in England. It is preferred to avoid carrying spoil more than 100 yards, and should filling be required at a greater distance than that, a fresh excavation would be opened. The bricks in use are of very inferior quality, and vary in price from 11s. to £1 per 1,000. There are three qualities of lime, burnt with coal, wood, or rubbish, costing 14s. 5d., 12s. 7d., or 9s. 9d. respectively per cubic yard. Brickwork may be estimated at 10s., and concrete at 5s. 9d., per cubic yard. Timber is mostly imported from Burmah, and wood, in roof trusses, &c., costs 5s per cubic foot.

MANCHESTER, 16th January, 1890.

The Ribble Bill.—The association of Preston ratepayers who are known as the "party of caution" intend to oppose the Bill promoted by the Corporation, and suggest the abandonment of all the works, with the exception of the dredging, which they think should be proceeded with. They contend that a coasting trade is all that can be cultivated at Preston. In view of the late Board of Trade inquiry, upon the report of which the proposed Bill is founded, it is hardly likely that the opposition will succeed.

A Fireless Motor.—It is stated that an extensive trial of the new tramway engine, in which the propulsion is due to ammonia in the form of gas, and to which we referred some months ago, is to be made at Bolton, where the gradients are heavy. The test is severe, but the owners—the Fireless Engine Syndicate—are determined to ascertain the true merits of the engine prior to putting it on the market.

Sewage Scheme.—The Hyde Town Council have determined to proceed with works to purify the sewage of the town. After inspecting a number of works they have determined to adopt the intermittent precipitation and filtration system pursued at Acton, in which magnetic ferrous carbon is used. Several other local bodies in the district propose to adopt this system.

The Late Mr. T. L. Daltry.—We regret to announce the death of Mr. Thomas Lewis Daltry, which took place on the 11th inst., in the thirty-sixth year of his age. Mr. Daltry was for some time editor of the *Mechanical World* and of the *Textile Manufacturer*, and was an engineer and inventor of considerable repute.

Watch Factory.—The new factory on the American system at Prescot, the erection of which was commenced last May, as noted in *Industries*, was formally opened by Lord Derby on the 11th inst. The company, which is responsible for the carrying out of the work, has for some months past been having watches made in some of the older workshops by special machinery, but it is now intended to put all the tools into the new works. Since the idea was first mooted it has been resolved to make the cases as well as the movements, so as to compete with the American and Swiss makers. Most of the employers in the district are shareholders in the new concern, and the present indications are of such a character that the promoters speak very confidently of future dividends.

The Linen and Jute Trades.—Travellers having now got back again on the road, orders have come in more freely, although the season has not yet opened out fully. Prospects, however, may be considered very good, as there is a distinct tendency on the part of retailers to keep bigger stocks, and the wholesale houses in accordance with this state of things have bought largely. A damask consisting of a silk and linen mixture, the product of French looms, has been shown lately, and the article is said to have sold well with American buyers. In this market, however, heavy and commoner varieties still constitute the bulk of the linen trade. Some of the heads of departments are away in the manufacturing districts. Others have returned and are now actively engaged in pushing sales. Prices are firm, the stiffness of jute having a tendency to make rates for linens steadier. Fancy jute fabrics promise well both in carpets and crumb cloths. Linen threads are in moderate request, and manufacturers are now obtaining more easily the rates which were established on the issue of the advanced lists last year.

GLASGOW, 16th January, 1890.

Pig Iron.—This has been a week of intense excitement in the iron market; a fall of about 6s. per ton, in the face of increasing cost and scarcity of fuel, seems to have taken most of the trade by surprise. The general impression left by the reports of the Birmingham meeting was good, but on the whole not favourable to any further rise in prices at present. The dealers and other outsiders in England, who have of late been the principal purchasers of warrants, seem to have held off from selling till after the Birmingham meeting, when they expected a strong market, but the result has been very disappointing to them, as our market was unable and unwilling to absorb, at the high prices, all the iron that came out on sale. As the prices drooped sellers became more urgent, and finally, in a state of semi-panic, Scotch and hematite warrants dropped on the 13th 2s. to 2s. 6d. per ton. On Tuesday they advanced again to above Monday's best, but close slightly lower.

Scotch Railways.—The Scotch railway traffic returns are still expanding. For last week the three great railways have all gained, the Caledonian by an increase of £5,000, the North British by £7,000, and the Glasgow and South Western by £3,000. A rumour prevailed in the end of last week that the Caledonian Railway Company had abandoned the Edinburgh underground railway scheme. This, however, is at least premature. The company, in spite of the opposition to their scheme which exists in Edinburgh, intend to proceed with the Bill.

The Coal Trade in 1889.—In their annual report, just issued, Messrs. D. M. Stevenson & Co., Glasgow and Leith, state the quantity exported in 1889 was 3,859,251 tons, an increase of 536,971 tons over the previous year. In regard to the trade of the year, prices, they say, have been much higher than in the previous year, the prices during the autumn being higher than has been the case for fifteen years.

Engineering.—The contract for the harbour tunnel to be constructed under the Clyde at Finnieston has been secured by Messrs. Hugh Kennedy & Sons, Partick. Messrs. Wilson & Simpson, C.E., are engineers. The tunnel will be in three divisions; two of the tunnels will be used for vehicles, and one for passengers. The operations will be begun immediately.—The erection of the new steel works of the Lanarkshire Steel Company, at Motherwell, has been begun. It is expected that they will be completed in three or four months.

Exhibition of Industrial Art.—A selection of exhibits from the Arts and Crafts Exhibition is to be opened free to the public on Saturday. A considerable part of the metal work, which was a feature of the Arts and Crafts this year, has been brought down.

(From our own Correspondents.)

LIVERPOOL, 15th January, 1890.

Appointment of the City Engineer.—On account of the appointment of Mr. Clement Dunscombe as engineer to the London County Council, Mr. Henry Percy Boulnois, borough engineer of Portsmouth, has been appointed as his successor. He is appointed as city engineer, gas inspector, and surveyor of buildings, at a salary of £850 per annum, with an annual increase of £50 until a maximum of £1,000 per annum is reached. He comes with excellent testimonials, and a record of former work which makes him well qualified to undertake the multifarious duties of his new office, and it was no compliment to him when the committee coupled his name with some others in the extraordinary selected list, which has justly given rise to surprise and indignation.

The Salt Trade.—The returns of salt exported from Cheshire during the last year show a serious diminution, the total amount being 745,111 tons, against 1,022,334 tons in 1888. There is a falling off of about 25,000 tons to the United States, and 15,000 tons to British North America; of 92,000 tons to Calcutta, 14,500 tons to Belgium, and about 22,000 tons to Russia and the North Sea ports.

Hydraulic Passenger Lifts at the Liverpool and London and Globe Offices.—These two lifts, which were fully described and illustrated in *Industries* a short time ago, have since been converted by Messrs. R. Waygood & Co. to high pressure lifts; and, instead of obtaining the very costly low pressure water from the Corporation mains, the supply is now obtained from the high pressure mains of the Hydraulic Power Company, and already the great economy of the latter is evident. Several other low pressure lifts are being converted, and all are anxious to avail themselves of the pressure from the new main which the company have at last been allowed to lay, in accordance with the recent agreement with the Corporation. In addition to the powers to be applied for in the next session to ratify their agreement, the company are seeking powers for laying down a similar system in Manchester.

LEEDS, 15th January, 1890.

The Iron and Steel Trades.—The confidence apparent in the quarterly meetings was reflected at our market yesterday. The new year has already seen a slight advance all round, and there are indications that before very long the prices of finished iron and steel will again rise from five to ten per cent. The iron and steel trades are very active, and manufacturers are almost daily asked to undertake fresh orders. Contracts are lost to the district, owing to the inability of makers to guarantee early delivery. Great

Digitized by Google

pressure is also being put upon engineers to execute work at early dates. New orders for all kinds of locomotives and machinery are being received, not only for home, but also for abroad, among the foreign customers being India, Australia, Turkey, Paris, and Mexico. There is not quite so much doing as there was a couple of months ago in heavy machinery for shipbuilding purposes, shipbuilders having supplied their wants, and there being for the present a cessation in the placing of new contracts for ships, on account of the high rates obtaining for manufactured iron and steel. The engineering outlook is very satisfactory—that is, with reference to demand. At the time of writing almost every establishment is as busy as possible Better prices rule, though the increased cost of production, both in regard to raw material, fuel, and labour, has a tendency to keep down profits. In view of the revival that has overtaken the engineering and machine trade, workmen are trying to improve their position, and accordingly the Leeds Executive Council of the Amalgamated Society of Engineers have issued revised rules relating to the wages and working hours of members employed in the district.

THE COAL TRADE.—The steam coal trade continues to be exceedingly brisk, and there is a fairly good demand for fuel for domestic purposes. Coke is also in great request, and somewhat difficult to obtain.

SHEFFIELD, 15TH JANUARY, 1890.

RAILWAY MATERIAL.—Great activity continues in all the branches specially devoted to the manufacture of railway material. At the works of Messrs. Craven Brothers an order has been received from the Great Northern Railway Company for the supply of 1,000 low-sided goods waggons, of exceptionally strong and massive construction. No diminution is noticeable in the volume of orders for tyres, axles, springs, &c. In wheels, the old cast iron centre has quite given place to the new form, in which the centre and spokes are united by two washers, and at a welding heat pressed together by hydraulic power.

COAL AND COKE.—There is very little change to report in this district. The miners have now received advances of 30 per cent. over the wages paid in July last, and it is to be desired that no further disturbances will take place for some time to come. Good coke continues to be scarce.

IRON AND STEEL.—The iron and steel manufacturers exhibit no signs of diminishing their output. The armour plate mills are fully employed, and ship plates, girders, and boiler plates continue to give plenty of work. Steel castings are in great demand for almost all purposes where strength and lightness is required. Ironfounders are also well off for employment.

NORTH STAFFORDSHIRE, 15TH JANUARY, 1890.

THE IRON TRADE.—Orders and specifications are coming in pretty freely, as a result of the quarterly meetings held last week. There was a good attendance of local ironmasters at Birmingham, and a fair business was done at advanced prices, the selling price of bars being £9 10s. per ton. The demand for pig iron was good, at prices varying from 70s. to 80s. per ton. Large sales were effected in puddle mine and furnace mine at prices showing a very considerable advance on those ruling at the October meeting.

GENERAL.—The Midland Coal, Iron, and Coke Company, with a capital of £375,000, has been formed to take over the collieries and ironworks at Apedale, Chesterton, and Podmore, formerly carried on by Messrs. Stanier & Co. and Messrs. Cooper & Craig.

BIRMINGHAM, 15TH JANUARY, 1890.

THE IRON AND STEEL TRADES.—There is in this district a continued strong demand for all kinds of iron and steel, but perhaps less disposition on the part of buyers to enter into new contracts for forward delivery. Most of the mills and forges are very busy on old contracts, and doing their utmost to wipe them off the books. A few orders are placed at current rates, and sellers will not enter them for forward delivery except at higher prices. The advance of marked bars on the 1st inst. to £9 10s. per ton at works helped to steady the market on quarter-day, Thursday last, and a fair amount of business was done. Common bars are to-day difficult to obtain under £9 per ton, sheets £10 5s., hoops £9 5s. For pig irons, of Staffordshire make, the prices range from 115s. for cold blast to 65s. for cinder pigs, but there are few sellers. There is a great demand for steel in all forms, and all steel works are taxed to the uttermost. Galvanised corrugated sheets are about £16 per ton at works.

GENERAL TRADE.—Chain and cable makers are very busy, but report a falling off of inquiries from the shipyards. Admiralty contractors, too, report a limited demand. The nail and rivet trades are very brisk. Makers of weighing machinery are very busy on work which is the result of the coming into operation of the new Weights and Measures Act. Traders are anxious to have their machines and weighing tackle put into order. Axle manufacturers are briskly employed, and have advanced prices 5 per cent. Vice, anvil, and shovel makers are busy. The strike in the Stourbridge brick trade interferes with business in that centre, and it is feared that it will last some time, as the operatives are well supported by contributions from other workmen's unions and federations, and the masters appear to be very firm. Kidderminster carpet weavers are exceptionally well employed, prices of wool are firm, and the prospect generally, for Kidderminster trade, is very good.

CARDIFF, 15TH JANUARY, 1890.

COAL AND COKE.—On account of the strikes in Belgium, a large number of orders for Welsh coal have arrived from that country. This, in addition to the rather heavy ordinary demand, has sent up prices for steam coal still further, and as much as 15s. 6d. has been paid for second-class qualities. The wages question having now been practically settled, business can be negotiated on a healthy footing. For coke the demand during the past week has been extraordinary, and as much as 28s. and 29s. has been paid for furnace coke, foundry quality realising some shillings above this figure. Ironmasters complain that the high prices of coke and iron ore are consuming the profit which otherwise they would have made over the present high prices of pig iron.

IRON STEEL AND IRON ORE.—The quarterly meetings last week showed how far buyers had neglected to keep their stocks up to a reasonable point, and high prices were paid for both steel bars and rails for prompt delivery. Makers had little or no pig iron to offer. The supply of iron ore seems well nigh exhausted, and buyers who have not covered themselves are in a dilemma. In fact, even those who have bought find all manner of difficulties arising in Spain, especially in Bilbao, about shipment. Rubio ore is quoted 17s. to 17s. 6d. c.i.f. Cardiff, second class quality. Freights from Bilbao are 5s. 6d.

BARROW-IN-FURNESS, 15TH JANUARY, 1890.

IRON AND STEEL.—The iron trade of the West Coast district is in a firm position, although a depression has commenced in the warrant market, resulting in the lowering of prices about 3s. per ton. Makers, however, have not changed their quotations, and are still asking 82s. 6d. per ton for parcels of mixed Bessemer iron net f.o.b., and 81s. 6d. for No. 3 forge and foundry iron, and are selling their products at these prices. There is some prospect of an increased output of pig iron. Stocks show an increase on the week of 830 tons. There are 56 furnaces in blast in the district, and 23 are standing idle. Steel makers are very busily employed, and plenty of new orders are offering for rails, plates, angles, tinplate bars, hoops, blooms, castings, and forgings. Heavy rails are still quoted at £7 5s. per ton, and colliery rails at £8 10s. More orders are offering for steel shipbuilding material than makers can accept. Prices remain very firm all round. Iron ore is brisk, and the mines are producing a larger weekly tonnage than was ever previously the case, but the native supply has to be augmented by foreign importations on a large scale.

SHIPBUILDING AND ENGINEERING.—The Naval Construction and Armaments Company at Barrow have orders in hand for 30,000 tons of shipping and for 60,000 i.h.p. in machinery. The company expect shortly to supplement this work with other orders.

MIDDLESBROUGH, 15TH JANUARY, 1890.

PIG IRON.—The speculators have again been at work, and have made the pig iron market unsteady. From 65s. for No. 3 G.M.B. the price dropped to 61s., but steadied itself there, and then rose to 61s. 6d., with a strong tendency to rise. There is not much business done, as regular customers do not care to buy with the prices so unsettled. No. 1 stands at about 64s., and grey forge at 60s. to 61s. In warrants Connal's No. 3 G.M.B. are quoted at 61s. to 61s. 3d. cash. In hematite, East Coast brands are quoted at from 80s. to 82s. 6d. for makers' iron, mixed numbers. On Monday, the 13th inst., the stock in Connal's store amounted to 184,208 tons, as against 183,248 tons on the previous Monday, showing an increase of 960 tons.

SHIPMENTS OF PIG IRON.—The shipments of pig iron are improving. Up to the 13th of the month they amounted to 19,065 tons, 5,070 of which went to Scotland, 6,650 to other parts of England, 1,140 to Germany and Holland, and 6,205 to other foreign countries. This is better than last month, but not so good as during the similar period last year.

MANUFACTURED IRON AND STEEL.—In the finished iron trade there is plenty of work going on, but there are few inquiries. Prices remain much the same. Ship plates are at £8 5s.; ship angles, £8; common bars, £8, with the usual discount. In the steel trade there is a steady business being done, and prices remain much the same. Ship plates are quoted at £9; angles, £8 10s.; rails (heavy), £7 5s. per ton on trucks at works.

COAL AND COKE.—Coal is steady at improved prices. There is not much done, however, except in odd lots, and the price varies. Households are rather dull. Coke is as scarce as ever, and as high in price.

SUNDERLAND, 15TH JANUARY, 1890.

SHIPBUILDING.—The prospects of this local industry for the current year are good. No other shipbuilding centre is comparatively so well situated. Amongst the orders most recently received are two steamships for the British India Steam Navigation Company, Limited, the recipients being Messrs. Wm. Doxford & Sons, Gallion. It will be remembered the "Mombassa" for the same company was completed during the past year by Mr. James Laing, Deptford. The recent petroleum fire on the River Wear is giving some work to ship-repairing establishments, as, although the fire was of short duration, the damage was exceedingly great. The fire occurred on the 8th inst., and was occasioned by a heated rivet falling into the river, whose surface was covered with petroleum discharged from the steamer "Wildflower" along with the water ballast. Besides the "Wildflower," the steamers "Douglass" and "Deronda," and the tug steamer "Earl of Dumfries," were badly damaged.

SHIPPING.—The freight market has not rallied fully as yet, but there are signs of improvement in outward Mediterranean rates. The short supply of coal has unfavourably influenced the outward rates of freight to all parts, but an early recovery may be anticipated. Coasting business is somewhat of an exception, and has not suffered to the same extent. As usual at the turn of the year, coal shipments are below the average.

NEWCASTLE, 15TH JANUARY, 1890.

RAILWAY WORKMEN'S HOURS.—Dr. R. S. Watson, who was selected to arbitrate upon the claim put forward by the employés of the North Eastern Railway Company at their various Newcastle goods stations, for the reduction of the working hours from ten to nine per day, has just issued his award, from which it appears that the concession asked for is given to porters and grain warehousemen, while it is denied to trolleymen, loftmen, and stablemen. The award possesses special interest, on account of the fact that it marks the first introduction of the nine hours working day among railway employés.

WAGES OF SHIPBUILDING OPERATIVES.—An advance of 5 per cent. on piece prices has just become due to certain sections of the shipbuilding operatives in the Tyne yards as a result of an agreement entered into between the employers and the representatives of the men in November last. It may be stated that this advance which is given to the platers, riveters, caulkers, and anglesmiths connected with the Boilermakers and Iron Shipbuilders' Society, brings the current wages rates very nearly up to the figures which ruled in 1882. On behalf of the members of the Amalgamated Engineers' Society a notice has been sent to the engineering employers of the district claiming an advance of 2s. per week at the end of the month, and also intimating the desire of the men that after the period indicated the day's work shall on Saturday terminate at noon, making the working hours 53 per week instead of 54 as at present. It is understood that a meeting between the employers and the representatives of the men will be held in the course of a few days to discuss these questions of wages and working hours.

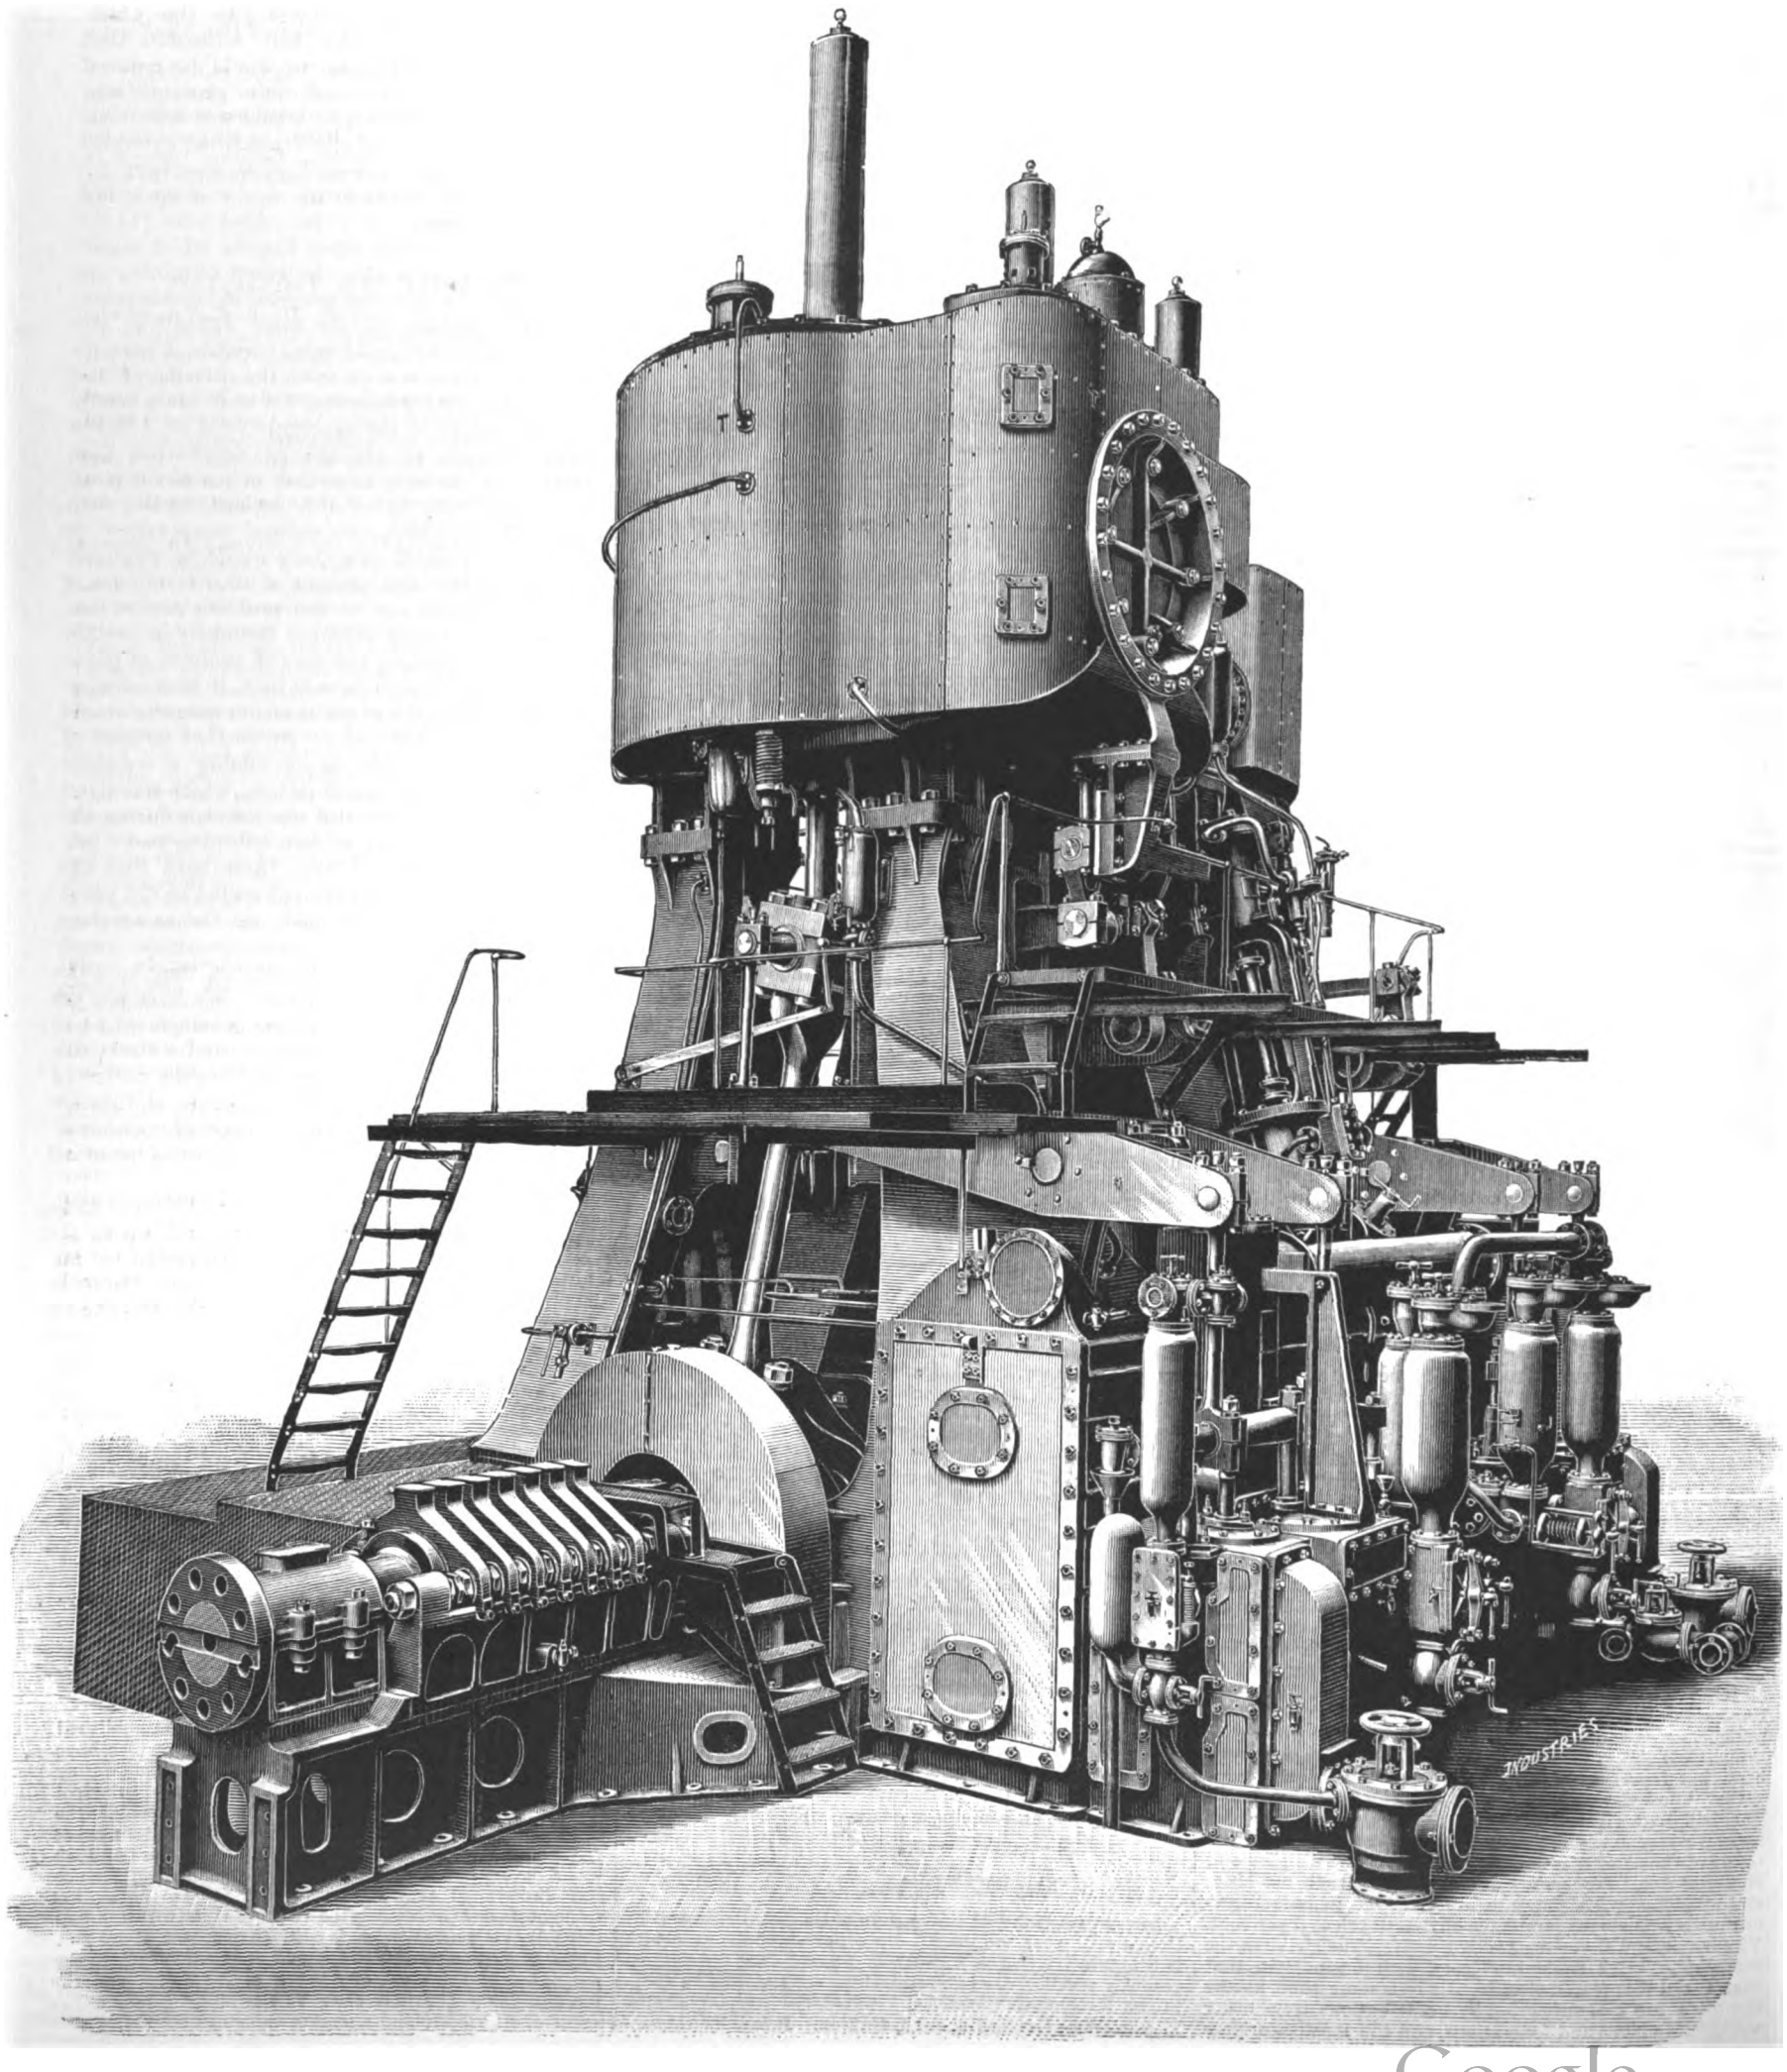
THE TIMBER TRADE.—Importations having for some time past almost entirely ceased, quietude now characterises this branch of business, and until the beginning of June no change in the direction of greater activity need be looked for. In the sawmills, however, there is a good deal doing, requirements for shipbuilding and housebuilding purposes being unusually large.

GLASS WORKS.—At the flint glass works the lull which usually follows the holiday period is now very generally felt, and the demand having declined, production has to a proportionate extent been restricted. In the plate glass works activity is still the feature, and bottle works are also very busy.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock for the week ending January 11th amounted to 101,918 tons, being an increase of 2,845 tons as compared with the shipments for the corresponding week last year.

DUNDEE, 15TH JANUARY, 1890.

JUTE AND FLAX TRADES.—The year has opened rather hopefully so far as the staple industries of this district are concerned. Prices of raw jute have, during the fortnight, tended against buyers, and there is a good demand for dock lots and near at hand parcels. Jute yarns are firmly held, but buyers are not operating largely. In the New York market burlaps are quoted ⅛c. above recent prices. Sacking and bagging are quiet, and tarpaulin is somewhat firmer. In consequence of an advance in the Russian Exchange there has been a rise in the price of flax. Stocks being low the shipment demand is good, but prices tend to restrict business. Flax and tow yarns have been rather easy. For linens some good American orders are reported, and manufacturers are well employed. There is more inquiry for sailcloth, and prices are firm.



LIMITED LIABILITY COMPANIES.—Statistics published with reference to limited liability companies which have their headquarters at Dundee indicate that business during 1889 has been fairly prosperous. Five of the principal shipping companies, with a paid-up capital of which the par value is £500,325, showed at the close of 1888 a market value of £415,403. The market value at the close of 1889 was £435,050, an increase of £20,000. Nineteen finance and investment companies showed a fall in the market value of 2 per cent. during the year; but notwithstanding this fall the market price is still 50 per cent. above par. Eight cattle companies, with a paid-up capital of which the par value at the close of 1888 was £2,070,076, and the market value £394,456, show at the close of 1889 a par value of £1,925,210 and a market value of £381,715.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, Bedford Street, Strand, London, W.C.*

FRIDAY, 17TH JANUARY, 1890.

THE DURATION OF OUR COAL SUPPLY.

IT is now almost a quarter of a century since Professor Jevons issued his book on "The Coal Question," and created so much interest on the subject that a Royal Commission was appointed to investigate it. Since that date our manufactures and population have gone on increasing, and it is necessary that the subject should be kept in mind, and that we should occasionally take stock of our coal supply, in order that we may anticipate, to a certain extent at least, the probable social and political consequences to ourselves and to the world of a partial exhaustion of our mines. Professor Jevons felt that these must be of an untoward, if not of a ruinous, character, and he wrote some solemn words of warning on the subject. He pointed out that, in the application of our Free Trade principles to our great national resources, we required to exercise great caution, for, while to part in trade with the surplus yearly interest of the soil may be unalloyed gain, to dispense so lavishly the cream of our industrial wealth is to be spendthrifts of our capital, as we part with that which will never come back. He reminded us of what is too often forgotten, viz., that after all commerce is but a means to an end—the diffusion of civilisation and wealth, and that to allow commerce to proceed until the source of civilisation is weakened and overturned is like killing the goose to get the golden eggs. He asked, moreover, the following momentous questions: Is the immediate creation of wealth to be our only object? Are the excellencies of Britain to be measured in tons and quarters, and our work in the world to be recorded only in her Custom House books? Have we not hereditary possessions in our just laws, our free and nobly developed constitution, our rich literature and philosophy, incomparably above material wealth, and which we are beyond all things bound to maintain, improve, and hand down in safety? And do we accomplish this duty in encouraging a growth of industry which must prove unstable, and perhaps involve all things in its fall? He came to the conclusion that the alternatives before us were simple. Our empire and race already comprise one-fifth of the world's population, and by our plantation of new States, by our guardianship of the seas, by our penetrating commerce, by the example of our just laws and firm constitution, and, above all, by the dissemination of our new arts, we stimulate the progress of mankind in a degree not to be measured. If we lavishly and boldly push forward in the creation and distribution of our riches, it is hard to over-estimate the pitch of beneficial influence to which we may attain in the present. But Professor Jevons was of opinion that the maintenance of such a position is physically impossible, and that we have to make the momentous choice between brief greatness and long-continued mediocrity. Neither of these alternatives was very pleasant to contemplate, and, in order that definite information might be obtained on the subject, a Royal Commission was appointed to investigate the whole question. Professor Jevons had estimated that in about one hundred years we would be reduced to sore straits for coal, and this prospect was sufficient to justify the alarm which was felt about the matter. The work of the Commission extended over five years, and embraced most searching inquiries into every department of the subject, but the two main questions to be solved were (1) the quantity of coal within these islands which might fairly be considered within the reach of mining appliances; (2) the rate and progress of consumption. This latter question was the more difficult of the two, as it involved a considerable number of assumptions. We need not go into the details of the figures of the Commissioners, but may state briefly that they estimated the aggregate total of 146,480 millions of tons as available at depths less than 4,000ft. At the same time they indicated the possibility of our working at still greater depths, even to 6,000ft., at which the natural temperature is 150° Fahr., in which case there would be rendered available an additional amount of 29,000 millions of tons. The calculation of the probable rate of consumption the Commissioners founded on certain assumptions regarding the rate of increase of population, and the result showed that, if that assumption were correct, the whole available quantity would be exhausted in 360 years. By another method of calculation—that is, by simply adding a constant quantity, namely, three million tons, which was about the average annual value of the increase during the previous fourteen years, to each following year's production—they computed from these data that the total supply of coal would be exhausted in 276 years. A third calculation was made on the assumption that the population would remain constant, simply oscillating without advancing, and in that case the coal would last over 1,200 years. We have not yet reached such a state of mental development as to justify this Spencerian assumption, and without this development it does not seem to be in the nature of the British people so to limit the rate of increase as practically to balance the decrease of population. The last calculation may, therefore, for all practical purposes be left out of account.

It is interesting to note how far the conclusions of the Commissioners have been verified up to the present time. This was recently attempted by Mr. Hall, one of Her Majesty's Inspectors of Mines, in his inaugural address as President of the Manchester Geological Society, and we will now proceed to quote a few of his figures and conclusions. The calculation of the Commissioners based on population he admits is difficult to follow, but, taking the various items into account, we must deduct at least 10 per cent. from the time named by them, which on the whole is not a very serious correction. By the second method of calculation, that of adding a constant quantity of three millions of tons to each year's production or consumption since 1869, in which year the coal raised amounted to 107 millions of tons—on this basis the production of 1888 works out to 164 millions of tons, and the actual statistics for 1888 show it to be 170 millions, which proves that the calculation of the Commissioners is only a little over three per cent. from the truth. But during the last ten years the average increase has been about four millions of tons per annum, and if we take this as what is likely to continue, then of course we must considerably reduce the time the coal fields are estimated to last. Whether it will continue is, however, a matter of speculation. Surely it is not beyond the bounds of possibility that other sources of energy besides that stored up in our coal fields may be taken advantage of. The applications of electricity, especially in the transmission of energy, open up great possibilities for the utilisation

Digitized by Google

of wind and water power, and even possibly of chemical combinations which are at present utterly unknown to us. It may stimulate ingenuity if we clearly realise the position we are in, and have an idea of what store of coal is actually within our reach. Mr. Hall does not think that with our present appliances we can depend on working at the greatest depths mentioned by the Commissioners. The temperature, calculated upon an increase of one degree for every sixty feet, he finds to be under the mark, and that at 4,000 feet the temperature would be actually 130° Fahr. This, of course, can be reduced somewhat by efficient systems of ventilation, but the majority of workers find it distressingly hot while working in a temperature of 80 degrees. Mr. Hall therefore concludes that, with our present knowledge and appliances—which, however, must not be considered incapable of extension and improvement—that when temperature due to depth reaches 100° Fahr., coal cannot be worked except at a very great expense, if at all. The question of cost of production as compared with that in other countries will probably be the factor which will have the most effect on our coal production, for as foreign countries develop their resources and reduce their cost, while our resources are gradually being exhausted and the cost of production increasing, naturally our foreign trade will diminish, and with swift steamers it might even pay to import coal. Mr. Hall gives some figures to show that many foreign countries are reducing the cost of production per ton to very nearly our figure. With us there has been an increase of about 9d. per ton since 1869, an increase which seems to be due to higher payments for labour, but whether for higher wages, or to more labour being required by deeper mining, is not made quite clear, although it is probably due to both of these causes.

It is pretty evident that we cannot safely calculate on our coal fields lasting more than 200 years at the most. This may seen a long period, and sufficiently far distant to relieve our statesmen of all responsibility in the matter, but that is not so. We have accumulated an immense national debt; our industrial prosperity has encouraged the growth of population to a great extent, and made us dependent for a great part of our food supply on foreign sources; and these and other reasons compel us to depend on our industries. In the intervening 200 years we have time to put our house in order, and make arrangements for a changed set of conditions. If our statesmen are wise, they will draw our Colonies into closer connection with the mother country, and gradually we will find that the resources of those will make up for our deficiencies, and that we shall have a much more powerful Empire than we have at present, although the centre of gravity of its trade and industry may have shifted in the direction of the new countries, while the old may have become the centre of a higher culture in every department of literature, science, and art.

HOURS OF LABOUR AND WAGES IN THE PAPER TRADE.

Notwithstanding the strikes and other difficulties which have occurred recently—possibly in consequence of them—there are many signs that we are rapidly approaching a time when the relations of capital and labour, and all disputes between employers and employed, will be settled by friendly conference or by arbitration, or even possibly when these will be rendered unnecessary by a system of profit-sharing or co-operation which will give workmen a sufficient voice in the management to prevent all misunderstanding. Before such a system, however, can be entirely successful, there must be more attention paid to economic and social science in our schools and colleges, so that the different parties may be able to realise all the bearings of the subject, and not simply look upon it from their own individual, and therefore selfish, point of view. It is for this reason that we have in all discussions on technical education endeavoured to place it on a wider basis than is usual, so that it may not only fit masters and workers to apply science and art to their trades and professions, but also enable them to see how these are co-related to the social and economic aspects of their mutual interests. Those who are engaged in any department of industry will, we think, be willing to admit that their greatest difficulties do not arise on the scientific or technical side of their work, but on the economic, and, as we have often pointed out, the one-sided technical education which is now given is apt to intensify the evils from which we are suffering. From the elementary school to the university, the chief lesson which the students learn is to look after their own personal interests, without regard to the welfare of their neighbours or the consequences to society, and hence it is that our material progress has far outrun our social and moral, and brought us face to face with the serious problems which are now puzzling statesmen and philanthropists. As we have said, there are signs of improvement, but, like many other advances we have made, we are to a large extent blundering on to a better state of matters through the expensive school of trial and error instead of deliberately preparing those who are to take part in the struggle by a system of education which would fit them to appreciate the arguments and positions taken by each party, and not simply intensify that selfishness which is the root of many of our difficulties.

The special case to which we wish to direct attention is that of the papermakers in Scotland. A meeting of the master papermakers was recently held in Edinburgh, for the purpose of considering a circular which they had received from their workmen, requesting an abatement in the hours of labour, and desiring that they should stop work on Saturday at two p.m. instead of what had been the practice previously in their various mills. Not only was the request of the workmen agreed to as far as is at present possible, but, what was of much more importance, the spirit displayed by the great majority of the employers augured well for the harmony of their future relations with their workmen. Mr. John James Cowan, of Pennycuik, moved, "That the master papermakers of Scotland, having considered the memorial from their workpeople, received by them individually, express sympathy with the desire for shorter hours therein contained, and trust that the kindly and sympathetic relations which have existed between employers and employed in the past may continue." Mr. Cowan pointed out the great agitation which was everywhere being carried on in the labour world, and dwelt on the necessity for them doing all in their power to promote the good feeling which had hitherto existed between employers and employed; and he was supported by the large majority of the employers, and a considerable reduction of working hours was arranged for, although not to the full extent asked for by the men. At the same time it was unanimously agreed that the workmen's request was reasonable, and that all efforts be employed to meet their wishes, as soon as the arrangements at the different mills would allow it. That this will soon be done may be inferred from the further resolution, which was carried unanimously. This resolution stated, "That with a view to the speedy and effectual carrying out of the above, the master papermakers agree to unite with their workpeople in a trade organisation, and appoint a committee to take such action as may be needed to carry this into effect." This again is a step in the direction which we have advocated. Combinations of masters and trades unions must, we are afraid, at least for a considerable time, remain practically as they are. But there ought to be an intermediate body, composed of representatives of both, which would meet occasionally for the arrangement of all matters of dispute. By a process of evolution we would have ultimately a real Trades Guild, which would look after the interests of all concerned in it, whether employers or employed. In fact, it might gradually lead to the abolition of the distinction between these two classes, by giving all an interest in the success of the works, and virtually making them all employers. The masters are beginning to get over the feeling that it is beneath their dignity to sit in council with their men in many departments of industry. In the Scotch paper trade the employers had almost always been on terms of very close intimacy with their workpeople, but even in it are to be found a few who look upon an organisation between masters and men as impossible, and one of these spoke at the meeting, but he found himself in a very small minority. It was pointed out that if the interests of capital and labour were one, what they had to do was for both parties to exercise forbearance, and that the best way was to cultivate relations of friendship with their men, and treat them as their equals. Mr. John Cowan, of Beesluck, who is one of the oldest papermakers in Scotland, referred to the long experience he had had of the relations between masters and men in the papermaking trade, and said that from his boyhood one of the duties he had been taught was to mingle with their people, and to come to a knowledge of them in their houses in all their circumstances, and he added that he had more true and faithful friends among the working classes than in any class in society. Mr. Cowan is a representative of a former generation, but we are glad to see that all classes of society are beginning to recognise the truth of what Carlyle dwelt upon many years ago, that a cash payment is not in itself a sufficient discharge of the duty of employers—a little human feeling will go far to smooth over difficulties and prevent disputes, and we trust that the example of the Scotch papermakers will be widely followed.

NOTES ON PATENTS.

I.

RIGHTS OF EMPLOYER AND WORKMAN.

In the ordinary course of business one has frequently to study the relations between employer and employed. Although they necessarily have common interests, and their prosperity is affected by the same causes, yet it often happens that there is friction between them, arising in many cases from a want of consideration of one party for the other. Not infrequently they quarrel over the matter of a patent. In connection with this the question is often asked, Has an employer any legal right to the inventions of his workmen? It seems established law that *a master has not, by the mere contract of workmanship, any right to the inventions of his workmen.*

Employers entertain very different views in respect of the justice of this rule. Some consider it a great hardship that they are not entitled to the inventions of their workmen. To formulate the employer's "grievance," it amounts to this:—"My man made the invention while in my employment; he probably used my tools and machinery, and the invention was suggested to him by the work on which he was engaged." Some employers feel still further aggrieved when they find out that a patent has been applied for without their concurrence. They entertain a feeling that they have been overreached in the matter. If it were possible to analyse this feeling it would be found that these employers are acutely sensitive on the question of their authority. Letters Patent, in fact, give the workman certain rights against the whole world which raise him from a position of subserviency.

The workman, on his part, thinks it very hard that he is not allowed to have the full benefit of his invention, and that there should be the least hindrance to his obtaining the reward for his invention. Workmen, however, have frequently to consider whether their patenting an invention would cause any annoyance. This is not mere sentiment. We have known the case of a man losing his employment when he told his employer that he had taken out a patent for an arrangement. Two or three instances have come before our notice where employers have said, "We don't allow our workmen to take out patents!"

We have briefly stated the views entertained by employers and workmen when they have disagreed on this matter. In the majority of cases the parties agree on the subject, not from there being an actual contract between them, but from mutual interest. In several works a premium is given to the workman who makes any invention. In many cases, however, there is an actual contract entered into when the workman comes into the service of the employer. We have seen contracts where the whole of the inventions of the workmen belong to the employer. We have also seen cases where, in the event of an invention by a workman, the employer is merely to have a free licence. Where the employer by express contract becomes entitled to the invention, the patent must be applied for by the inventor. By the Patent Act of 1883, it is provided that any other person can apply for the patent jointly with the inventor. Nothing is more simple than that there should be an agreement between the employer and workman as to inventions. In drafting such an agreement great care should be exercised. It must be so drawn as not to stifle the inventive genius of the workman. The employer might with fairness have a licence, free from royalty, to use any invention made during the service of the man in his works. The man, we think, ought to have free disposal of the patent, subject to this exception. The agreement ought not to be too severe, as that would stifle the invention, or cause the inventor to evade the contract. An agreement properly made, taking into consideration the rights of employer and workman, is most likely to work to the interest of both. The suggested agreement would, of course, not be applicable where the employé is specifically employed for the purpose of making inventions. For instance, in large chemical works, sometimes five or six chemists are employed with the express purpose of experimenting. They are paid for making the experiments, and the results of their investigation naturally belong to the employer.

It may be worthy of notice that the Crown had, before the Patent Act of 1883, the right to use the invention of the subject, and even now inventors in the "services" have to obtain leave to patent their inventions.

Digitized by Google

Up to the present we have been considering the inventions of the workman, and the employer's rights with relation thereto.

This must not be confused with the employer's inventions on which he may instruct his workman. It seems settled law that an inventor can obtain assistance to develop and bring his invention to perfection. It not infrequently happens that when an assistant is working out his principal's ideas, he not merely develops, but introduces some discovery of his own. It becomes then a very nice question as to whether he should join in applying for the Letters Patent. If it be a mere development, the inventor can fairly include it in his own invention. If the development constitutes a new departure, it would be certainly safer for the patent to be applied for in the names of the inventor and his assistant. The principal would, however, be most imprudent in adopting this course, unless a written agreement was drawn up, regulating their rights when the patent is granted.

The rights of co-patentees and co-owners of patents form the most unsettled branch of our patent law.

COAL, IRON, AND COGNATE INDUSTRIES.

The Board of Trade returns, of which we give some particulars herewith, are now published for the month of December and for the twelve months then ended. At the commencement of a new year and of a new decade —and that the last of the present century—some retrospect is desirable. We have already bestowed some considerable space to statistical and commercial summaries, and, except so far as our usual *résumé* of the Board of Trade returns is concerned, this article will be confined to a consideration of the "tone" of the markets in the various centres of the industries under review. The value of the imports for the month of December was £38,267,934, being an increase of about one per cent. on the total of December, 1888. The aggregate value for the past year was £427,210,839, being an increase of £39,575,096 as compared with 1888. The value of the exports for the month of December was £20,903,353, being an increase of 11 per cent. on the total of December, 1888. The aggregate value for the past year was £248,091,959, being an increase of £14,249,352 as compared with 1888. It may be noted that the figures for both imports and exports are higher than have hitherto been reached. The quantities of iron and steel exported during December and during the year show an increase, as compared with 1888, of 19,543 tons and 221,825 tons respectively, the values showing an increase of £141,364 and £2,736,735 respectively. With regard to the year's trading, it may be remarked that there has been an appreciable increase in our exports of raw iron to Germany, Holland, and Russia, and of railroad iron to Mexico, while under this latter head a heavy falling off is noticeable in our business with Japan and the United States, and there has also been a large decrease in the case of bar and angle iron with British East Indies and British North America. We utilise our tabular statement for a comparison of the aggregate exports for the past three years:—

	1889.	1888.	1887.
Pig and puddled	£2,987,546	£2,206,373	£2,741,507
Bar, angle, &c.	1,624,403	1,658,308	1,447,977
Railroad.....	5,339,304	4,669,215	4,617,460
Steel, unwrought	1,700,963	1,572,754	2,094,454
Coal.....	14,793,655	11,345,299	10,176,402

Turning to the home markets, we find a condition of things more satisfactory than has presented itself for some fifteen years. The revival which commenced in the latter half of 1888 has proceeded with leaps and bounds. At each of the quarterly meetings held during the year prices of finished iron and the crude metal have been advanced, and materials of all descriptions have partaken of the improvement. Scotch warrants, which in January were selling at about 44s., have this month reached 66s. Middlesbrough warrants have risen during the same period from 33s. 6d. to 65s. 6d., hematites from 45s. 6d. to 80s. Common bars have advanced from about £5 10s. per ton to £9 10s. per ton, steel rails from £4 10s. to £8 10s., and all through the category similar improvement in values can be recorded. There can be no doubt that works which were formerly entirely unremunerative to, or actually carried on at a loss by, their proprietors are now paying well. Others that succumbed to the pressure of the times have been re-started and reorganised. The shares of all public companies connected with these industries have greatly risen in price. On the crest of the wave of prosperity many private concerns have been launched under the Limited Liability Acts. The record of 1889 bears testimony to the inherent vitality in apparently moribund industries, and deals a severe blow to the pessimism of 1888. It is a remarkable fact that this change has been brought about by the adjustment of the laws of supply and demand rather than by the adoption of all or any of the panacea of trade faddists.

As is only just and right under the circumstances, the labour market has participated to the full in the improvement in trade. Since October, 1888, colliers' wages have been advanced 30 per cent., and those of ironworkers and blast furnacemen in proportion. We leave for a further article the consideration of future prospects.

THE LATE MR. DANIEL ADAMSON.

It is with great regret that we announce the death of Mr. Daniel Adamson, which took place at his residence, at Didsbury, near Manchester, on Monday, the 13th inst. It is not often that an engineer's name becomes a household word, or that the average citizen is cognisant of the standing of a technical or scientific man. But this was a distinction which was awarded to Mr. Adamson, especially in the north of England, and not so much from his brilliant inventions or high mental abilities as from his desire to benefit the world in general by overcoming natural surrounding difficulties. Of course this popularity was due to a large extent to the devotion which he showed towards the fortunes of the Manchester Ship Canal in its early days, but in other circles his reputation was made by the excellence of the boiler and other engineering work which he undertook. The practical introduction and commercial success of the modern methods of steel making were due, to a large extent, to the enterprise and courage of Mr. Adamson, as he was, we believe, the first to adopt Bessemer steel in the construction of steam boilers. Mr. Adamson has

always followed the developments of steel manufacture with characteristic energy and enthusiasm, and his services in that direction have been recognised on all hands, from Sir Henry Bessemer to the youngest member of the Iron and Steel Institute. Mr. Adamson only resigned the Presidentship of the Iron and Steel Institute a year ago, and he held a prominent position in several other societies.

It will be of interest to follow briefly the fortunes of Mr. Adamson from his youth upwards, in order to see by what steps a man of ability may rise from insignificance into a distinguished position. He was born in 1820 at Shildon, in Durham, and at an early age was apprenticed to Mr. Timothy Hackworth, of the Stockton and Darlington Railway, who was the first of a gradually lengthening list of locomotive superintendents, and a notable figure in early locomotive history. After a time he was appointed engineering manager of that railway, and in 1850 he left Durham to become general manager of the Heaton Foundry, Stockport. Shortly afterwards he started a works of his own at Newton, but soon removed to more extensive premises at Hyde, in Cheshire. Since that time the firm which he established, and now known as Daniel Adamson & Co., has rapidly increased in importance, and at present it is one of the largest establishments of the kind in England.

Mr. Adamson has in his time introduced many improvements in engineering practice. In 1862 he patented a special machine for drilling holes in boiler plates instead of punching them, and about the same time he adopted what is now known as the Adamson flange seam for the furnaces of internally fired boilers with the view of preventing their collapse.

In 1882 he commenced the agitation in favour of the construction of a ship canal for Manchester, and by his energies he aroused the interest of the population of Lancashire, and the burden of sustaining the Parliamentary inquiry practically rested with him alone at one period of the long and anxious struggle. After his efforts had been crowned with success the floating of the company by the aid of Messrs. Rothschilds was unfortunately attended with failure, and in the re-modelling of the board of directors and of the plans of the company Mr. Adamson felt himself compelled to withdraw. Since that time the ship canal has gone on satisfactorily, and all difficulties have been overcome, but the inception and the initial success was after all due to Mr. Adamson, who will be long remembered as a distinguished engineer of remarkable energy and inventive capacity, and in Lancashire, at least, as a high spirited benefactor in the public interest.

We give herewith a portrait of Mr. Adamson, which has been reproduced from a photograph taken by Messrs. Elliott & Fry.

Letters to the Editor.

IMPROVED CHAIR AND SLEEPER.

To the Editor of "Industries."

Sir,—Referring to the illustrated description given in your issue of last week of our improved chair and sleeper, permit me to point out that the new sleepers have been in use with ordinary chairs for two years on the North Stafford Railway at Stoke-on-Trent, and have given great satisfaction. In proof of this, I may add that we have received a large order this week from the same company.

Yours, &c.
(For the Chair and Sleeper Company, Limited),
J. W. White.

Widnes, January 15th, 1890.

STEAM BOILER LEGISLATION.

To the Editor of "Industries."

Sir,—The facts given in your leader on steam boiler legislation are calculated to cause some alarm among outsiders. The risk of a boiler explosion affects not only the owner of the same, but his neighbours. An idea has been prevalent that if a boiler was insured this was a guarantee against accidents happening. This, however, appears not to be the case. As a matter of business policy, most persons would think that a company insuring a boiler would make it compulsory that the owner should adopt such measures as the company's inspector considered necessary for its safety. You state that this is contrary to the companies' policies, but this appears to be a very bad principle to work upon economically. It follows that even if an inspector announces that a boiler will blow up after another day's use, that his employers are liable to pay the insurance on it if the owner chooses to risk continuing it at work. I understand that several boiler insurance companies have come to grief of late, and such regulations as these suffice to account for this result. A fire insurance company bases its premiums on the risks run by the property insured, and the same would be a good policy in the case of boiler insurance companies. If it be considered advisable to retain the clause you mention, namely, that the insured are under no obligation to adopt any suggestions in the insurance company's report, it would only be judicious to insist, if the advice given was not followed, that the premium should be higher than for new boilers which required no stipulations.

The "Charlesworth" boiler was fifteen or sixteen years old when it burst. During that time it had never been thoroughly examined, but after a preliminary and apparently superficial examination a policy was granted upon it. In the interests of the shareholders of the company no policy should be issued without a complete inspection. I gather from your remarks that the action of the Engine, Boiler, and Employers' Liability Insurance Company is not exceptional, but if this be the case the whole system is radically wrong.

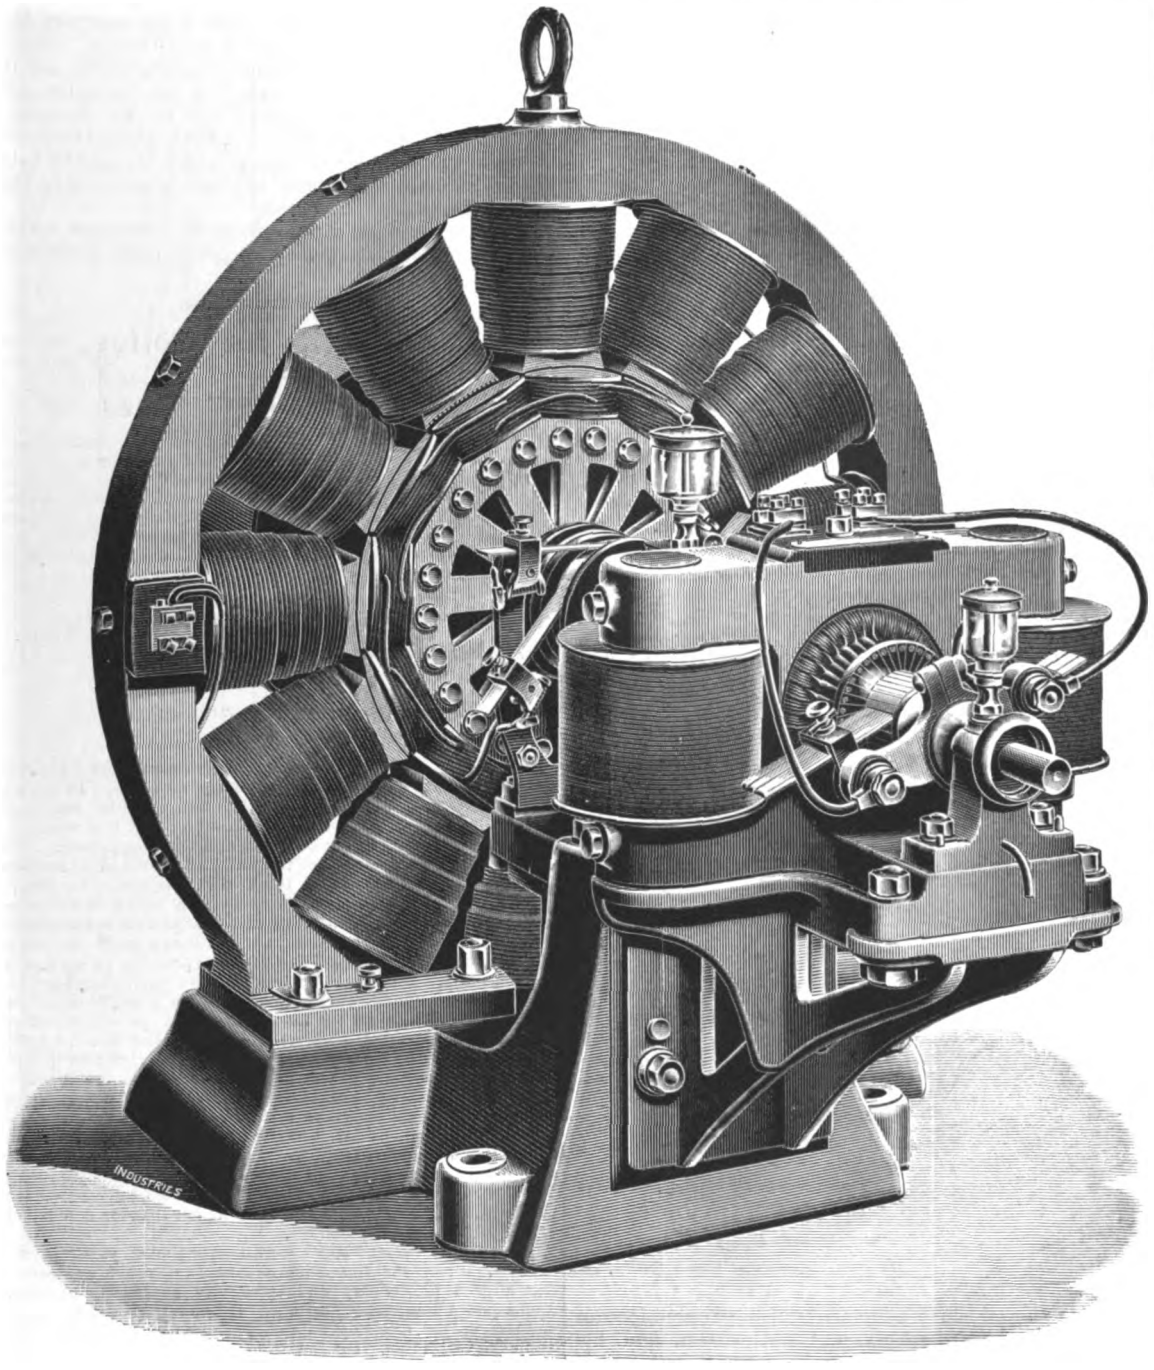
Under these circumstances a boiler insurance company proceeds on the lines of a life assurance company. The latter does not guarantee the life of the assured, and the former does not pay any attention to the prospects of the life of the boiler. A distinction exists in the fact that the life office regulates its terms by the health of the man insuring, whereas the boiler office charges the same price for a good or bad boiler. In fire offices, the sensible plan also prevails of charging premiums according to the risks.

The utility of a boiler insurance company would be mostly evident if it would undertake that no explosion would take place with any boiler under its auspices. Railway collisions and some other engineering mishaps are unavoidable, but there is no reason whatever why any boiler should explode. All that is necessary is that it should be in good condition and under proper control. Neither of these qualifications should be difficult to attain.

Yours, &c.,
Policy.

London, 13th January, 1890.

To the Editor of "Industries."



Sir,—I have read with pleasure your valuable article in your issue of last week on the above subject, and though I do not entirely agree with all it contains, I think it an admirable and opportune warning to steam users generally. Something must be done to keep down these disastrous explosions, and if steam users will not take warning and adopt means to reduce the number of explosions, someone else will, and then it will be too late either to attempt milder measures or to complain of the inconveniences attending Government interference.

I would here point out that you are in error in stating that only "three formal investigations have been held." Seven have been held to my certain knowledge. The "Charlesworth" and the "Development" cases, being fresh to the memories of your

Digitized by Google

ALTERNATE CURRENT DYNAMO.

CONSTRUCTED BY MESSRS. MATHER & PLATT, SALFORD IRONWORKS, MANCHESTER.

readers, have not yet been formally reported on, while four other cases have—the reports of which are now before me. The first formal investigation was held in connection with No. 254 explosion, at Broxmoor, Staffordshire, in which case no penalty was imposed. The next was No. 355, in connection with an explosion on a fishing boat of Yarmouth, where the owner was fined or "ordered to pay" £20 for acts of his agents. The case was briefly as follows: The owner was advised to put in a new boiler by an inspecting engineer, but did not follow the advice. The foreman, however, knew that the skipper systematically wedged down the safety valve. The inspecting engineer was practically censured for his imperfect examinations, and for not remonstrating with the skipper for wedging down the valve. The next was No. 361, when a forge boiler exploded at Wallsend-on-Tyne, the owner being ordered to pay £50. The next is No. 367, at an iron foundry at Bromley-by-Bow, in which case the owner was ordered to pay £40, after promising to pay at least £100 to a youth who had lost his sight through the explosion. The other case, not yet reported, is that of a steam wherry at Newcastle-on-Tyne, where the owner was fined £65. In this case it would appear that one insurance company actually refused to insure the boiler on account of the weak firebox, which was said to be distorted and collapsed in four places. Another company was then called in who insured it, even in this condition. The latter company is now, I am informed, defunct; but does it not point to a very unhealthy state of things in boiler insurance competition? Would not a monopoly, with all its faults, be better than such a state of things?

Now, Sir, it is all very well to think these salutary lessons will eventually have a bearing on the minds of steam users; but how many steam users are there who hear about them? When the leading engineering journals of the day do not know of them, how can outsiders be expected to hear of them? An explosion occurs, all within sound hear of it, an investigation is held and reported in local papers. Then a few days elapse and all is over. Would not a more public announcement be of some use?

With respect to the inertness of the Board of Trade in these investigations, I would just remark that when the Act of 1882 was passed, it instituted an entirely new department and new work for the people who had to investigate these explosions, and, however skilful and experienced as marine engineers the Board of Trade surveyors may have been, they were at that time certainly unsuited for the work. But are the present reports of inquiries what they were then? Have they not gained experience since 1882, and shown that they have confidence to say who is the guilty party? The present condition of things is what has been asked for by many men in this district, namely, a proper use of the Act of 1882, and if it will not waken steam users to a sense of responsibility, their slumbering will assuredly strengthen the hands of those who intend to put in action that drastic legislation so much dreaded. I hope that the matter may be taken up by an abler and freer pen.

Yours, &c.,

S. BOSWELL.

Manchester, 13th January, 1890.

THE ENGINES OF THE S.S. "FRIESLAND."

As promised last week, we now give some further particulars of the engines of the s.s. "Friesland," which were illustrated in our issues of July 17th, 1889, and the 10th inst. The cylinders are 35½in., 56in., and 89in. in diameter respectively, and the stroke is 4ft. 6in. They are supported on massive cast iron columns at both front and back. The high and intermediate cylinders have piston-valves, while the low-pressure has a slide valve, the valve gear being the ordinary link motion. For stopping and reversing a Brown's steam and hydraulic starting engine is provided. The condenser is of the ordinary box type, having 8,000 sq. ft. of cooling surface, and a vacuum of 29in. was maintained when the engines were running full speed, and indicating about about 5,000 i.h.p. The air pumps, two in number, are worked from the H.P. and L.P. cross-heads respectively by the usual rocking arms and links, and are fitted with Kinghorn's patent valves. Two of Gwynne's centrifugal pumps circulate the water through the condenser, each of them being capable of doing the whole work. Weir's feed-pumps and heater are fitted, and also an evaporator by the same firm for supplying the boilers with fresh water, to make up the various losses which occur. An auxiliary condenser of 750 sq. ft. cooling surface is provided, into which the drains from steam heating pipes, galleys, &c., are led, thus saving the loss of a considerable amount of fresh water. The circulating water is supplied by a 5in. Gwynne's centrifugal pump. Steam is supplied by three double-ended and one single-ended boiler, having twenty-one furnaces in all, and working at 160lb. pressure. Though not worked on the forced draught system under air pressure, the boilers are entirely dependent for their air supply on four large double-breasted fans. This method enables steam to be maintained as steadily in hot calm weather as at other times; the discharge from the fans is so arranged as to give an even distribution of air over the whole stokehold.

For the steam trials, which took place in the last week in November, the ship was brought down by means of cargo and water ballast to her seagoing trim, and the speed obtained under these conditions was as follows:—Mean of six runs on measured mile, equal to 14·76 knots, the mean revolutions being 74 per minute. Then, on a continuous run of 12 hours' duration, the mean revolutions were 72·5 per minute, corresponding to a speed of 14½ knots. During the run the i.h.p. was 4,700, and the total coal consumed was 40 tons of Scotch coal.

On the first outward voyage from Antwerp to New York the weather was exceptionally severe, so that nothing in the shape of a record passage could be attempted; but on the homeward run the distance from Sandyhook to Flushing was accomplished in 9 days 13 hours 50 minutes, or at a mean speed of 14·3 knots per hour, thus making the fastest passage on record between these two ports.

MESSRS. MATHER & PLATT'S ALTERNATE CURRENT DYNAMO.

MESSRS. MATHER & PLATT, of the Salford Ironworks, Manchester, are now manufacturing an alternate current dynamo, which embodies several new features, and has given very satisfactory results in practice. As is the case with most alternate current machines in which the armature contains iron cores, the armature revolves and the magnets are fixed. The magnets are of wrought iron, and are arranged round the armature, exterior to it, and are attached to a massive cast iron ring which forms the yoke connecting the limbs. The attachment is so arranged that any of the magnet cores can be removed without disturbing the remainder or taking out the armature. The armature is constructed of two plates or discs keyed on the shaft, between which the armature cores are held by bolts. As with the magnets, any section of the armature can be removed without disturbing the remainder. Apertures in the discs allow free ventilation of the armature cores.

The magnets are excited by a Mather & Platt's "Manchester" dynamo, which is carried on a bracket bolted to the bedplate of the alternator, the armature shafts being coupled direct. The whole arrangement is exceedingly compact, occupying little floor space. The machines are manufactured under the patents of Dr. John Hopkinson and Dr. Edward Hopkinson, and are made in several standard sizes up to 100 Board of Trade units. For working with transformers they are constructed either for 1,000 or 2,000 volts, and from 8,000 to 12,000 alternations per minute, or with a "periodicity" of from 66 to 100. The machines can be run in parallel perfectly, and may be thrown into parallel working without the least danger, even when there is considerable difference between the electromotive forces at the terminals or when the machines are running at different speeds.

The machine illustrated is for an output of 1,000 volts and 30 amperes, at 800 revolutions per minute. The armature resistance is 0·55 ohms, and the resistance of the magnets 2 ohms. When working with full load the current through the magnet coils is 21 amperes, showing an electrical efficiency of over 95 per cent. Messrs. Mather & Platt have already constructed several of these machines for central station work, and have a number now in course of construction.

IMPROVED "SILENT" AIR PROPELLER.

CONSTRUCTED BY MESSRS. B. VERITY & SONS, ENGINEERS AND ELECTRICIANS, LONDON.

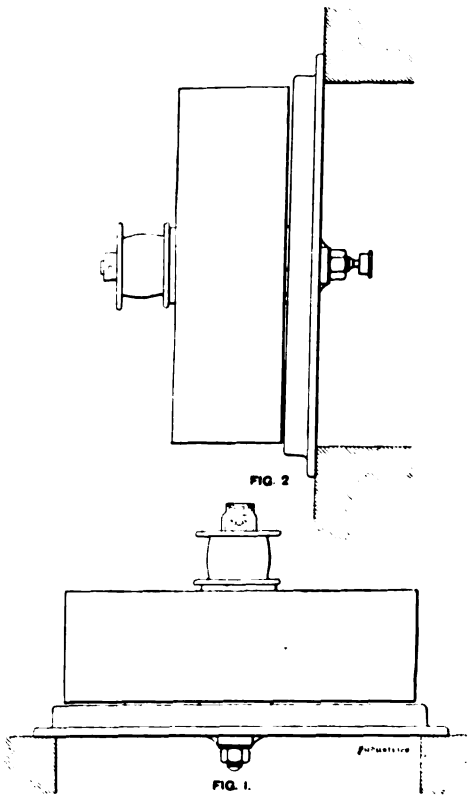

FIG. 3.

FIG. 4.

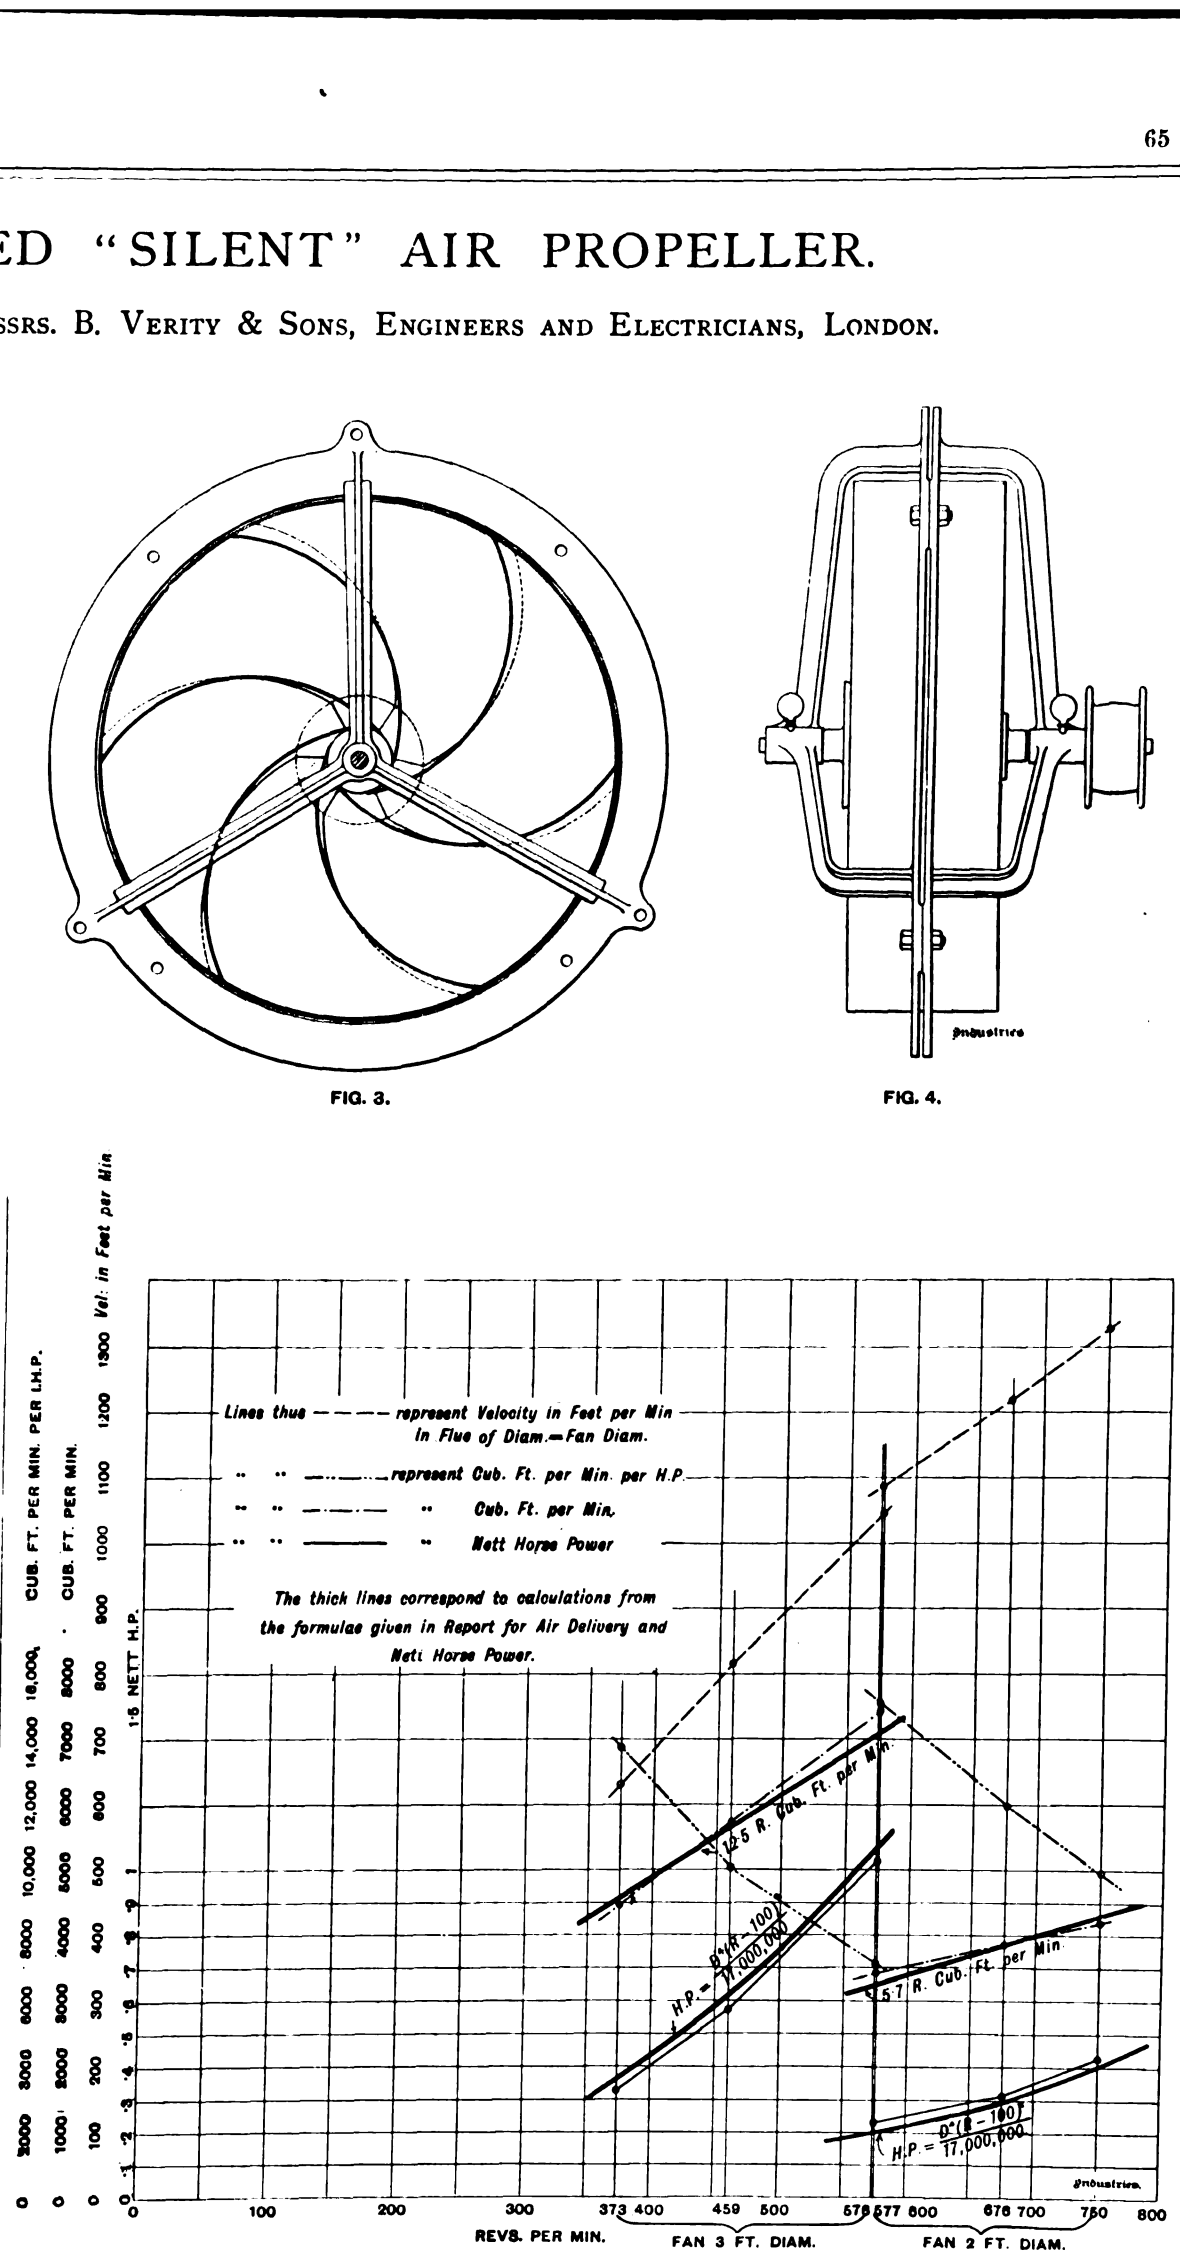
THE VERITY "SILENT" AIR PROPELLER

A FEW months ago Messrs. B. Verity & Sons, King Street, Covent Garden, London, brought out a new form of air propeller, which we here illustrate. In order that the efficiency of the propeller should be accurately known, and that intending purchasers should have some definite and reliable information to go on, Messrs. Verity asked Professor A. B. W. Kennedy to make a series of experiments from an impartial standpoint. The report of Professor Kennedy's experiments is here subjoined. We understand that these fans have been supplied to the Savoy Theatre, and that they are giving every satisfaction on account of their noiselessness and general efficiency. They are also being supplied to Mr. D'Oyly Carte's new theatre in Shaftesbury Avenue, where the electric lighting installation is also in the hands of Messrs. Verity. The fans are particularly adapted for being driven by small electromotors.

In Fig. 1 the fan is arranged in the ceiling of a room for extracting air from below. The spindle is vertical and is fixed, and the weight of the fan is carried by a hard steel disc. A very small amount of lubrication is necessary. In Fig. 2 the same fan is mounted on a horizontal spindle. In Figs. 3 and 4 the spindle revolves in two bearings carried by a ring frame which is made in halves and bolted together.

REPORT ON EXPERIMENTS ON TWO VENTILATING FANS (AIR PROPELLERS) AT THE WORKS OF MESSRS. B. VERITY & SONS, KING STREET, COVENT GARDEN, NOVEMBER 18, 19, 21, AND 25, 1889. BY PROF. A. B. W. KENNEDY.

I have pleasure in forwarding you the following statement of the results of the trials which I have made, at your request, of two patent ventilating fans constructed at your works.



The fans which I tested were respectively 2ft. and 3ft. in diameter, and I conducted my experiments so as to determine the net horse-power required to drive each fan at three different speeds and the quantity of air delivered by each fan at each speed.

Each fan was arranged for testing at your works to my instructions. The tests were conducted in a large room, and the fan placed only a few feet distant from a window which had an area of about 16 square feet, and from which I had had the whole of the glass removed. The spindle of the fan was placed horizontally about 3ft. from the floor, and the fan frame was connected to one end of a zinc flue, 3ft. diameter and 10ft. 6in. long, the other end of which projected through a door freely into the open air.

The fan under test was driven by a small Immisch electric motor, the speed of which could be easily regulated by resistances, the current being obtained from the dynamo and cells in use at your works. The rate of speed by motor to speed of fan, in revolutions per minute, was about 2·6 in the case of the large and 2·0 in the case of the smaller fan.

The work done on the motor by the current was measured in watts by frequent readings of a volt and an ampere meter, both of Siemens' make. The revolutions made by the motor and by the fan were each taken by a hand counter every two or three minutes. The net work taken up by the fan I determined by a series of thirty-six short experiments, coming after the fan trials, in which a simple rope brake was substituted for the fan. The motor was driven at each of the principal speeds at which it was worked for the trials, and with as nearly as possible the same current at the same potential. Its mechanical efficiency under each set of conditions was therefore directly determined, and from this the net power necessary to drive the fan (including the power for driving the belt) has been found at once.

The measurement of the quantity of air set in motion by the fan was not quite so simple. I used for this purpose a 3in. fan anemometer kindly lent me by Mr. Bryan Donkin, Jun., an instrument which he had calibrated by direct experiment upon a large scale. I believe, therefore, that its readings, which I have corrected in accordance with Mr. Donkin's calibration, are practically correct, the error, if a sensible one, being probably in the direction of an under-estimate of the velocity. I placed the anemometer upon a slide on a bar crossing the flue horizontally about 5ft. 6in. from the fan. As the air in the flue at such a place (or indeed anywhere throughout its length) would have very different velocities at different radii in any cross section, I measured the

Digitized by Google

velocity always in four different positions on the diameter—viz., at 1½in. from the edge, at 6in. and at 12in. from the edge, and at the centre. I allowed the anemometer to occupy each position for from 5 to 10 minutes at a time, during which interval the speed of the motor, the speed of the fan, and the electrical h.p. were each read at least twice. To calculate the quantity of air actually passing through the flue, I assumed that the velocity recorded by the anemometer in each position was the mean velocity of a cylinder of air whose mean radius corresponded to the position of the anemometer. The inner of these cylinders would be 6in. diameter, the next 18in. outside and 6in. inside, the next 30in. diameter outside and 18in. inside, and the outermost 36in. diameter outside and 30in. inside. By multiplying the velocity registered by the anemometer in each position by the area of the corresponding cylindrical ring and adding together all the products, there is obtained the total quantity of air delivered per minute. By dividing this quantity by the total area of the flue, we obtain the mean velocity of the air.

The principal results of the experiments, worked out in the fashion described, are given in Tables I. and II., and are also shown graphically in the diagram on page 65. The tables give the results so clearly that they do not need much explanation. It will be seen that in each case the efficiency of the fan, that is, the quantity of air delivered per effective horse-power, increases very rapidly as the speed diminishes, so that lower speeds are much more economical than higher ones. On the other hand, as the quantity of air delivered *per revolution* is very nearly constant (see last line of each table), the actual useful work done by the fan increases almost directly with its speed. Comparing the large and small fans with about *the same air delivery*, the former (running at a much lower speed, of course) is much the more economical. Comparing the two fans running *at the same speed*, however, the smaller fan is very much the more economical. Comparing the last lines in the two tables, it will be seen that the delivery of air per revolution of fan is very nearly indeed directly proportional to the area of the fan's diameter.

The last line but one in each table shows the motion given to the air (in feet) per revolution of fan, which may be called the effective pitch of the air propeller. It may be interesting for you to compare this with the very different actual pitch of the propeller blades.

In case it may be of use to you in the proportioning of these fans I append a few formulæ deduced empirically from the results of the experiments. The thickest lines in the diagram correspond to those formulæ and show clearly to what extent they accurately represent the results obtained.

The air delivered per minute by the 3ft. fan is nearly 12·5 R cubic feet (R being the number of revolutions made by the fan per minute). For the 2ft. fan the quantity is 5·7 R cubic feet. For either of these or any other *similar* fans of which the area is A square feet, the delivery will be about 1·8 A R cubic feet. Of course any change in the pitch of the blades might entirely change these figures.

The net h.p. taken up is not far from proportional to the square of the number of revolutions above 100 per minute. Thus for the 3ft. fan the net h.p. is—

$$\frac{(R - 100)^2}{200{,}000},$$

while for the 2ft. fan the net h.p. is—

$$\frac{(R - 100)^2}{1{,}000{,}000}$$

It will be noticed that the denominators of these two fractions are very nearly proportional inversely to the square of the fan areas or the fourth power of the fan diameters. The net h.p. required to drive a fan of diameter D feet or area A square feet, at a speed of R revolutions per minute, will therefore be approximately—

$$\frac{D^4 (R - 100)^2}{17{,}000{,}000} \quad \text{or} \quad \frac{A^2 (R - 100)^2}{10{,}400{,}000}$$

Of course, I have in all these cases rounded the figures off, but the formula in this simple form gives results which correspond very fairly with the average of the experimental results. They must only be applied, however, to fans whose blades are arranged similarly to the blades of those I tested, and which do not differ much from these in any of their proportions.

It is right that I should state that the fans worked exceedingly well throughout the experiments. There was not the least sign of heating of the spindle, even at the highest speeds. The 2ft. fan may literally be said to be absolutely noiseless at all speeds. The 3ft. fan was also noiseless up to over 450 revolutions per minutes. At 550 revolutions it gave a low roar, which, however, was hardly audible 12 yards away in the same room. It may therefore also be honestly called a noiseless ventilator.

TABLE I.

PRINCIPAL RESULTS OF EXPERIMENTS WITH VERITY AIR PROPELLER, 3FT. DIAMETER.

Speed of fan revolutions per minute..	576	459	373
Net h.p. to drive fan and belt	1·02	0·575	0·324
Cubic feet of air per minute	7,400	5,800	4,470
Mean velocity of air in 3ft. flue (feet per minute)	1,046	820	632
Cubic feet of air per minute per effective h.p.	7,250	10,070	13,800
Motion given to air per revolution of fan (feet)	1·82	1·79	1·70
Cubic feet of air per revolution of fan	12·8	12·6	12·0

TABLE II.

PRINCIPAL RESULTS OF EXPERIMENTS WITH VERITY AIR PROPELLER, 2FT. DIAMETER.

Speed of fan revolutions per minute..	750	676	577
Net h.p. to drive fan and belt	0·42	0·32	0·227
Cubic feet of air per minute.....	4,183	3,830	3,410
Mean velocity of air in 3ft. flue (feet per minute)	593	543	482
Mean velocity of air in flue, same diameter as fan	1,330	1,220	1,085
Cubic feet of air per minute per effective h.p.	9,980	11,970	15,000
Motion given to air per revolution of fan (feet)	1·77	1·81	1·88
Cubic feet of air per revolution of fan	5·58	5·66	5·90

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of this society, on the 9th inst., Dr. John Hopkinson, F.R.S., President, delivered his inaugural address, taking as his subject "Magnetism." We give the first part of this address, and the remainder will appear in our next issue.

As old as any part of electrical science is the knowledge that a needle or bar of steel which has been touched with a loadstone will point to the north. Long before the first experiments of Galvani and Volta the general properties of steel magnets had been observed—how like poles repelled each other, and unlike attracted each other; how the parts of a broken magnet were each complete magnets with a pair of poles. The general character of the earth's magnetism has long been known—that the earth behaves with regard to magnets as though it had two magnetic poles respectively near the rotative poles, and that these poles have a slow secular motion. For many years the earth's magnetism has been the subject of careful study by the most powerful minds. Gauss organised a staff of voluntary observers, and applied his unsurpassed powers of mathematical analysis to obtaining from their results all that could be learned.

The magnetism of iron ships is of so much importance in navigation that a good deal of the time of men of great power has been devoted to its study. It was *the* scientific study of Archibald Smith; and Airy and Thomson have added not a little to our practical knowledge of the disturbance of the compass by the iron of the ship. Sir W. Thomson, in addition to much valuable practical work on the compass, and experimental work on magnetism, has given the most complete and elegant mathematical theory of the subject. Of late years the development of the dynamo machine has directed attention to the magnetisation of iron from a different point of view, and a very great deal has been done by many workers to ascertain the facts regarding the magnetic properties of iron. The upshot of these many years of study by practical men interested in the mariner's compass or in dynamo machines by theoretical men interested in looking into the nature of things, is that, although we know a great many facts about magnetism, and a great deal about the relation of these facts to each other, we are as ignorant as ever we were as to any reason why the earth is a magnet, as to why its magnetic poles are in slow motion in relation to its substance, or as to why iron, nickel, and cobalt are magnetic, and nothing else, so far as we know, is to any practical extent. In most branches of science the more facts we know the more fully we recognise a continuity, in virtue of which we see the same property running through all the various forms of matter. It is not so in magnetism; here the more we know the more remarkably exceptional does the property appear, the less chance does there seem to be of resolving it into anything else. It seems to me that I cannot better occupy the present occasion than by recalling your attention to, and inviting discussion of, some of those salient properties of magnetism as exhibited by iron, nickel, and cobalt—properties most of them very familiar, but properties which any theory of magnetism must reckon with and explain. We shall not touch on the great subject of the earth as a magnet—though much has been recently done, particularly by Rücker and Thorpe, but deal simply with magnetism as a property of these three bodies, and consider its natural history, and how it varies with the varying condition of the material.

To fix our ideas, let us consider, then, a ring of uniform section of any convenient area and diameter. Let us suppose this ring to be wound with copper wire, the convolutions being insulated. Over the copper wire let us suppose that a second wire is wound, also insulated, the coils of each wire being arranged as are the coils of any ordinary modern transformer. Let us suppose that the ends of the inner coil, which we will call the secondary coil, are connected to a ballistic galvanometer; and that the ends of the outer coil, called the primary, are connected, through a key for reversing the current, with a battery. If the current in the primary coil is reversed, the galvanometer needle is observed to receive a sudden or impulsive deflection, indicating that for a short time an electromotive force has been acting on the secondary coil. If the resistance of the secondary circuit is varied, the sudden deflection of the galvanometer needle varies inversely as the resistance. With constant resistance of the secondary circuit the deflection varies as the number of convolutions in the secondary circuit. If the ring upon which the coils of copper wire are wound is made of wood or glass—or, indeed, of 99 out of every 100 substances which could be proposed—we should find that for a given current in the primary coil the deflection of the galvanometer in the secondary circuit is substantially the same. The ring may be of copper, of gold, of wood, or glass—it may be solid or it may be hollow—it makes no difference in the deflection of the galvanometer. We find, further, that with the vast majority of substances the deflection of the galvanometer in the secondary circuit is proportional to the current in the primary circuit. If, however, the ring be of soft iron, we find that the conditions are enormously different. In the first place, the deflections of the galvanometer are very many times as great as if the ring were made of glass, or copper, or wood. In the second place, the deflections on the galvanometer in the secondary circuit are not proportional to the current in the primary circuit; but as the current in the primary circuit is step by step increased we find that the galvanometer deflections increase somewhat, as is illustrated in the accompanying curve (Fig. 1), in which the abscissæ are proportional to the primary current, and the ordinates are proportional to the galvanometer deflections. You observe that as the primary current is increased the galvanometer deflection increases at first at a certain rate; as the primary current attains a certain value the rate at which the deflection increases therewith is rapidly increased, as shown in the upward turn in the curve. This rate of increase is maintained for a time, but only for a time. When the primary current attains a certain value the curve bends downward, indicating that the deflections of the galvanometer are now increasing less rapidly as the primary current is increased; if the primary current be still continually increased, the galvanometer deflections increase less and less rapidly.

Now what I want to particularly impress upon you is the enormous difference which exists between soft iron on the one hand, and ordinary substances on the other. On this diagram I have taken the galvanometer deflections to the same scale for iron, and for such substances as glass or wood. You see that the deflections in the case of glass or wood, to the same scale, are so small as to be absolutely inappreciable, whilst the deflection for iron at one point of the curve is something like 2,000 times as great as for non-magnetic substances. This extraordinary property is possessed by only two other substances besides iron—cobalt and nickel. On the same figure are curves showing on the same scale what would be the deflections for cobalt and nickel, taken from Professor Rowland's paper. You observe that they show the same general characteristics as iron, but in a rather less degree. Still, it is obvious that these substances may be broadly classed with iron in contradistinction to the great mass of other bodies. On the other hand, diamagnetic bodies belong distinctly to the other class. If the deflection with a non-magnetic ring be unity, that with iron, as already stated, may be as much as 2,000; that with bismuth, the most powerful diamagnetic known, is 0·999825—a quantity differing very little from unity. Note, then, the first fact which any theory of magnetism has to explain is: Iron, nickel, and cobalt, all enormously magnetic; other substances practically non-magnetic. A second fact is: With most bodies the action of the primary current on the secondary circuit is strictly proportional to the primary current; with magnetic bodies it is by no means so.

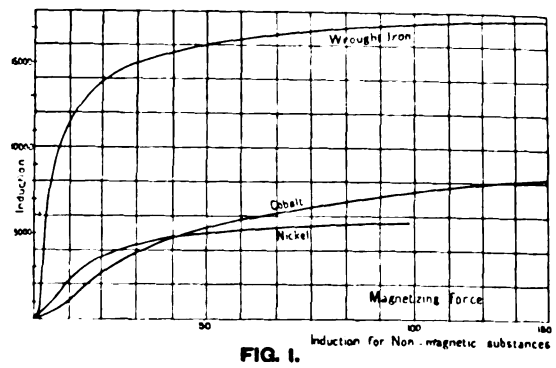


FIG. I.

You will observe that the ordinates in these curves, which are proportional to the kicks or elongations of the galvanometer, are called induction, and that the abscissæ are called magnetising force. Let us see a little more precisely what we mean by the terms, and what are the units of measurement taken. The elongation of the galvanometer measures an impulsive electromotive force—an electromotive force acting for a very short time. Charge a condenser to a known potential, and discharge it through the galvanometer; the needle of the galvanometer will swing aside through a number of divisions proportional to the quantity of electricity in the condenser—that is, to the capacity and the potential. From this we may calculate the quantity of electricity required to give a unit elongation. Multiply this by the actual resistance of the secondary circuit and we have the impulsive electromotive force in volts and seconds, which will, in the particular secondary circuit, give a unit elongation. We must multiply this by 10^8 to have it in absolute C.G.S. units. Now the induction is the impulsive electromotive force in absolute C.G.S. units divided by the number of secondary coils and by the area of section of the ring in square centimetres. The line integral of magnetising force is the current in the primary in absolute C.G.S. units—that is, one-tenth of the current in amperes—multiplied by 4π. The magnetising force is the line integral divided by the length of the line over which that line integral is distributed. This is, in truth, not exactly the same for all points of the section of the ring—an imperfection so far as it goes in the ring method of experiment. The absolute electromagnetic C.G.S. units have been so chosen that if the ring be perfectly non-magnetic the induction is equal to the magnetising force. We may refer later to the permeability, as Sir W. Thomson calls it; it is the ratio of the induction to the magnetising force causing it, and is usually denoted by μ.

There is a further difference between the limited class of magnetic bodies and the great class which are non-magnetic. To show this, we may suppose our experiment with the ring to be varied in one or other of two or three different ways. To fix our ideas, let us suppose that the secondary coil is collected in one part of the ring, which, provided that the number of turns in the secondary is maintained the same, will make no difference in the result in the galvanometer. Let us suppose, further, that the ring is divided, so that its parts may be plucked from one another, and the secondary coil entirely withdrawn from the ring. If now the primary current have a certain value, and if the ring be plucked apart and the secondary coil withdrawn, we shall find that, whatever be the substance of which the ring is composed, the galvanometer deflection is one-half of what it would have been if the primary current had been reversed. I should perhaps say approximately one-half, as it is not quite strictly the case in some samples of steel, although, broadly speaking, it is one-half. This is natural enough, for the exciting cause is reduced from—let us call it a positive value, to nothing when the secondary coil is withdrawn; it is changed from a positive value to an equal and opposite negative value when the primary current is reversed. Now comes the third characteristic difference between the magnetic bodies and the non-magnetic. Suppose that, instead of plucking the ring apart when the current had a certain value, the current was raised to this value and then gradually diminished to nothing, and that then the ring was plucked apart and the secondary coil withdrawn. If the ring be non-magnetic, we find that there is no deflection of the galvanometer; but, on the other hand, if the ring be of iron, we find a very large deflection, amounting, it may be, to 80 or 90 per cent. of the deflection caused by the withdrawal of the coil when the current had its full value. Whatever be the property that the passing of the primary current has imparted to the iron, it is clear that the iron retains a large part of this property after the current has ceased. We may push the experiment a stage further. Suppose that the current in the primary is raised to a

Digitized by Google

great value, and is then slowly diminished to a smaller value, and that the ring is opened and the secondary coil withdrawn. With most substances we find that the galvanometer deflection is precisely the same as if the current had been simply raised to its final value. It is not so with iron; the galvanometer deflection depends not alone upon the current at the moment of withdrawal, but on the current to which the ring has been previously subjected. We may then draw another curve (Fig. 2) representing the galvanometer deflections produced when the current has been raised to a high value and has been subsequently reduced to a value indicated by the abscissæ. This curve may be properly called a descending curve. In the case of ordinary bodies this curve is a straight line coincident with the straight line of the ascending curve, but for iron it is a curve such as is represented in the diagram. You observe that this curve descends to nothing like zero when the current is reduced to zero; and that when the current is not only diminished to zero, but is reversed, the galvanometer deflection only becomes zero when the reversed current has a substantial value. This property possessed by magnetic bodies of retaining that which is impressed upon them by the primary current has been called by Professor Ewing "hysteresis," or, as similar properties have been observed in quite other connections, "magnetic hysteresis." The name is a good one, and has been adopted. Broadly speaking, the induction as measured by the galvanometer deflection is independent of the time during which the successive currents have acted, and depends only upon their magnitude and order of succession. Some recent experiments of Professor Ewing, however, seem to show a well-marked time effect. There are curious features in these experiments which require more elucidation.

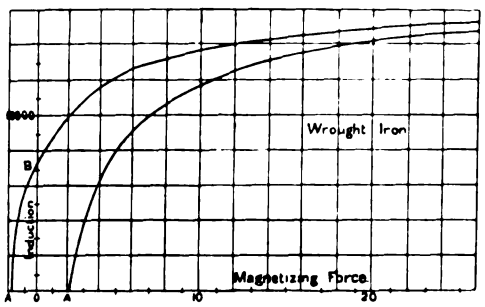

FIG. 2.

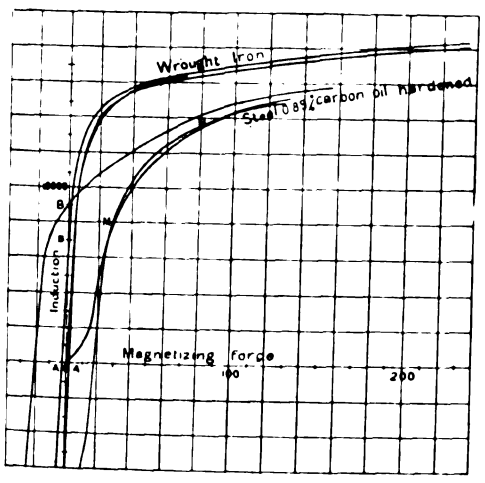

FIG. 3.

It has been pointed out by Warburg, and subsequently by Ewing, that the area of curve 2 is a measure of the quantity of energy expended in changing the magnetism of the mass of iron from that produced by the current in one direction to that produced by the current in the opposite direction and back again. The energy expended with varying amplitude of magnetising forces has been determined for iron, and also for large magnetising forces for a considerable variety of samples of steel. Different sorts of iron and steel differ from each other very greatly in this respect. For example, the energy lost in a complete cycle of reversals in a sample of Whitworth's mild steel was about 10,000 ergs per cubic centimetre; in oil-hardened hard steel it was near 100,000, and in tungsten steel it was near 200,000—a range of variation of 20 to 1. It is, of course, of the greatest possible importance to keep this quantity low in the case of armatures of dynamos, and in that of the cores of transformers. If the armature of a dynamo machine be made of good iron, the loss from hysteresis may easily be less than 1 per cent.; if, however, to take an extreme case, it were made of tungsten steel, it would readily amount to 20 per cent. In the case of transformers and alternate-current dynamo machines, where the number of reversals per second is great, the loss of power by hysteresis of the iron, and the consequent heating, become very important. The loss of power by hysteresis increases more rapidly than does the induction. Hence it is not well in such machines to work the iron to anything like the same intensity of induction as is desirable in ordinary continuous-current machines. The quantity O A when measured in proper units, as already explained—that is to say, the reversed magnetic force, which just suffices to reduce the induction as measured by the kick on the galvanometer to nothing after the material has been submitted to a very great magnetising force—is called the "coercive force," giving a definite meaning to a term which has long been used in a somewhat indefinite sense. The quantity is really the important one in judging the magnetism of short permanent magnets. The residual magnetism, O B, is then practically of no interest at all; the magnetic moment depends almost entirely upon the coercive force. The range of magnitude is somewhat greater than in the case of the energy dissipated in a complete reversal. For very soft iron the coercive force is 1·6 C.G.S. units; for tungsten steel, the most suitable material for magnets, it is 51 in the same units. A very good guess may be made of the amount of coercive force in a sample of iron or steel by the form of the ascending curve, determined as I described at first. This is readily seen by inspection of Fig. 3, which shows the curves in the cases of wrought iron, and steel containing 0·9 per cent. of carbon. With the wrought iron a rapid ascent of the ascending curve is made, when the magnetising force is small and the coercive force is small; in the case of the hard steel the ascent of the curve is made with a larger magnetising current, and the coercive force is large. There is one curious feature shown in the curve for hard steel which may, so far as I know, be observed in all magnetisable substances: the ascending curve twice cuts the descending curve, as at M and N. This peculiarity was, so far as I know, first observed by Professor G. Wiedemann.

I have already called emphatic attention to the fact that magnetic substances are enormously magnetic, and that non-magnetic substances are hardly at all magnetic; there is between the two classes no intermediate class. The magnetic property of iron is exceedingly easily destroyed. If iron be alloyed with 12 per cent. of manganese, the kick on the galvanometer which the material will give, if made into a ring, is only about 25 per cent. greater than is the case with the most completely non-magnetic material, instead of being some hundreds of times as great, as would be the case with iron. Further, with this manganese steel, the kick on the galvanometer is strictly proportional to the magnetising current in the primary, and the material shows no sign of hysteresis. In short, all its properties would be fully accounted for if we supposed that manganese steel consisted of a perfectly non-magnetic material, with a small percentage of metallic iron mechanically admixed

FIG. 4.

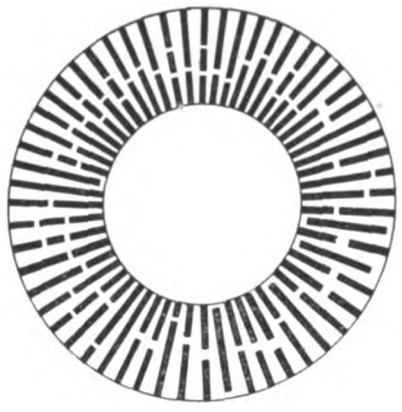

FIG. 5.

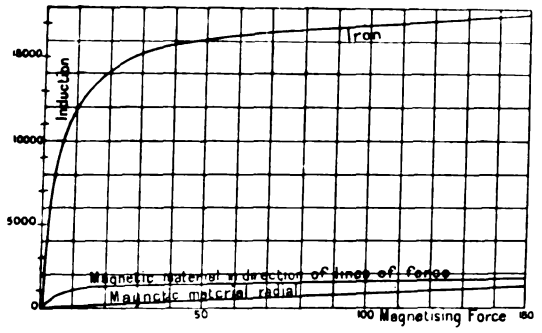

FIG. 6.

therewith. Thus the property of non-magnetisability of manganese steel is an excellent proof of the fact—which is also shown by the non-magnetic properties of most compounds of iron—that the property appertains to the molecule, and not to the atom; or, to put it in another way, suppose that we were to imagine manganese steel broken up into small particles, as these particles became smaller there would at length arrive a point at which the iron and the manganese would be entirely separated from each other: when this point is reached the particles of iron are non-magnetic. By the magnetic molecule of the substance we mean the smallest part which has all the magnetic properties of the mass. The magnetic molecule must be big enough to contain its proportion of manganese. In iron, then, we must have a collection of particles of such magnitude that it would be possible for the manganese to enter into each of them, to constitute an element of the magnet. Manganese is, so far as I know, a non-magnetic element. Smaller proportions of manganese reduce the magnetic property in a somewhat less degree, the reduction being greater as the quantity of manganese is greater. It appeared very possible that the non-magnetic property of manganese steel was due to the coercive force being very great—that, in fact, in all experiments we were still on that part of the magnetisation curve below the rapid rise, and that if the steel were submitted to greater forces it would presently prove to be magnetic, like other kinds of steel. Professor Ewing, however, has submitted manganese steel to very great forces indeed, and finds that its magnetism is always proportional to the magnetising force.

No single body is known having the property of capacity for magnetism in a degree which is neither very great nor very small, but intermediate between the two extremes. We can, however, mix magnetic and non-magnetic substances to form bodies apparently intermediate. It is, therefore, interesting to consider what the properties might be of such a mixture. It depends quite as much on the way in which the magnetic part is arranged in the mass, as on its actual quantity. Suppose, for example, it is arranged as in Fig. 4—in threads or plates having a very long axis in the direction of the magnetising force—we may at once determine the curve of magnetisation of the mixture from that of the magnetic substance by dividing the induction for any given force in the ratio of the whole volume to the volume of magnetic substance. If, on the other hand, it is as in Fig. 5—with a very short axis in the direction of the force, and a long axis perpendicular thereto—we can equally construct the curve of magnetisation. This is done in Fig. 6, which shows the curve when nine-tenths of the material is highly magnetic iron arranged as in Fig. 5, whilst the other curve of the same figure is that when only one-tenth is magnetic, but arranged as in Fig. 4. You observe how very different is the character of the curve—a difference which is reduced by the much less proportion of magnetic material in the mixture in the one case than in the other. One peculiarity of these arrangements of the two materials in relation to each other is that the resulting material is not isotropic—that is, its properties are not the same in all directions, but depend upon the direction of the magnetising force in the material. Of course, this is not at all a probable arrangement, but it is instructive in showing the character of the result as depending upon the construction of the material. Let us, however, consider the simplest isotropic arrangement; let us suppose that one material is in the form of spheres bedded in a matrix of the other: if the spheres are placed at random this is clearly an isotropic arrangement. The result is very different according as the matrix or the spheres are of the magnetic material. Suppose that the volume of the spheres is one-half of the whole volume. In Fig. 7 we have approximately the curve for

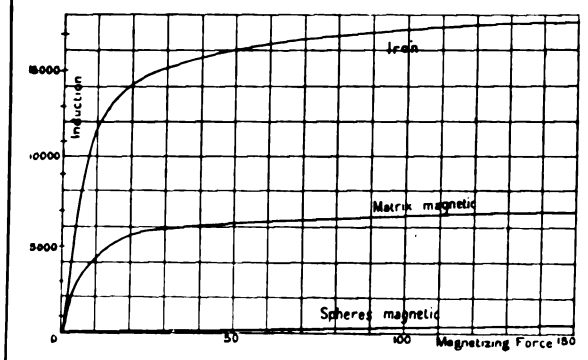

FIG. 7

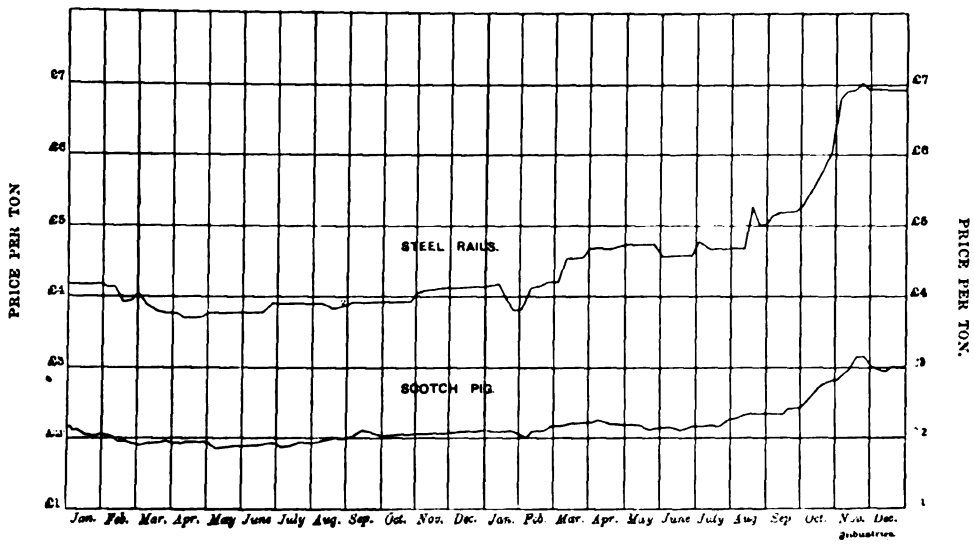
iron, for a mixture of equal quantities of iron and a non-magnetic material, the spheres being non-magnetic and the matrix iron, and for a mixture, the spheres being iron, and the matrix non-magnetic. Observe the great difference. When the spheres are iron the induction is near four times the force for all values of the force. When the matrix is iron the induction is near 2-5ths of the induction when the material is iron only.

(To be continued.)

THE SOCIETY OF CHEMICAL INDUSTRY.

MANCHESTER SECTION.



At the meeting held on the 7th inst., Dr. J. B. Cohen read the following communication from the Owens College Chemical Laboratory, on "A New Method of Estimating Sulphur in Iron and Steel."

After briefly describing the existing methods for the determination of sulphur in iron and steel, he called attention to the demand for rapid methods of analysis, and described a new process similar in principle to Eggertz's method, which consists in treating the metal with an acid and allowing the sulphuretted hydrogen evolved to produce a stain on a silver plate. In the new process a special apparatus is used, and the gas evolved acts on a piece of calico soaked in cadmium acetate, whereby stains of varying tints of yellow are produced. The stains are then compared with a standard series. The apparatus employed consists of a small flask, to which is joined a glass cylinder with a calico cover; there is a stoppered funnel at the side for admitting the acid. The method is stated to be equally applicable for large or small percentages, from ·002 to 1·5 per cent. of sulphur having been accurately determined. The process occupies half an hour.

Dr. Cohen and Mr. Brownsword also communicated a note on "The Nature of the Acid Distillate from a Rosin Still." The acid nature of the distillate from a rosin still is due to acetic acid, of which as much as 12 per cent.

Digitized by Google

CHART SHOWING THE VARIATION IN THE PRICES OF STEEL RAILS AND SCOTCH PIG DURING 1888 AND 1889.

1888. 1889.

has been found, partly as free acid and partly as acetate of iron. The acid was identified by the preparation of glacial acetic acid, and the analysis of the silver salt, which gave the numbers required by theory.

Dr. Cohen and Mr. R. W. Oddy then read a paper on "The Strength of Permanganate Solution." The object of this paper was to observe the change taking place in potassium permanganate solution on keeping. A solution was prepared, strength 5 grams to a litre, and carefully titrated with (1) iron wire and H_2SO_4, (2) ferrous ammonium sulphate. The solution was then divided into two parts, one being kept in the dark and the other in the light for four months. The strength was then redetermined at intervals. The results were tabulated, and show that the change of strength does not exceed the limit of experimental error in analysis.

Dr. Cohen and Mr. Oddy then submitted a paper on "Estimation of Organic Nitrogen," a comparison of the (1) Dumas, (2) Wanklyn, and (3) Kjeldahl methods. The tests were made on isinglass, and the numbers obtained were (1) 15·22, (2) 12·75, (3) 13·5 per cent. N. They conclude that Wanklyn's method gives too low results, and Kjeldahl's method, though suitable for manures, also gives low results in the case of bodies only decomposed with difficulty.

A paper was then read on "The Estimation of Alkalies in Soda Ash in the Presence of Sulphites," by Dr. Cohen and Mr. J. Grant. The method consists in boiling the soda ash with a small quantity of hydrogen peroxide, whereby the sulphites are oxidised to sulphates; the alkalies are then determined by titration as usual. The authors have observed the action of hydrogen peroxide on the various indicators and on pure alkalies, and find that it does not interfere with the analysis.

The last paper was by Mr. J. A. Wilson, on "The Rate of Distillation of Acetic Acid." In the valuation of crude acetic acid and acetates, the substance is distilled with phosphoric acid, and the acetic acid in the distillate titrated with soda. The author finds that nine-tenths of the acid comes over in the first distillate, and can thus estimate the percentage without adding water and distilling again.

NEWCASTLE SECTION.

On the 9th inst. a paper by Dr. Lunge, on "The Gas Volumetric Analysis of Potassium Permanganate, Bleaching Powder, and Manganese Dioxide," was communicated to the Section. The method proposed is similar in principle to that employed for estimating urea in urine. To the side tube of a nitrometer is attached by india-rubber tubing a small flask, containing an inner tube. In the flask is placed a known weight of permanganate solution, bleaching powder, or manganese dioxide, and in the tube a solution of hydrogen peroxide made alkaline with soda. When the pressure in the apparatus has been brought to the normal, the two liquids are mixed, and the evolved gas allowed to depress the column of liquid in the nitrometer tube. After adjusting the level of the liquids in the two limbs the volume of evolved gas is measured.

This method gives rapidly very accurate results, and compares favourably with the processes of standardising permanganate with iron wire or oxalic acid, and also with Perrot's method for the estimation of chlorine in bleaching powder.

Notes.

SAFETY OF ELECTRICITY.

Mr. Ferranti and Mr. Ince are not usually troubled with a *cacoethes scribendi*, so we are agreeably surprised to find an able contribution from their pens in our contemporary, *Engineering*. It is a pity a few articles like these—technically correct as well as popularly written, and also written by acknowledged authorities—do not find their way into the daily press.

PROFIT SHARING.

The schemes for enabling workmen to participate in the success of their firm are gradually spreading, and although workmen occasionally try to take an ell when they are given an inch, yet no doubt eventually employés will come to see that the advantages of such systems of profit sharing are as great as they can desire. The latest example to employers was announced at the annual dinner given to their workmen by Messrs. Lee & Hunt, of the Arkwright Tool Works, Nottingham. The scheme practically comes to this: After working expenses have been paid, the firm are to receive 5 per cent. interest on their capital, and 10 per cent. of the surplus is to be put aside as a mutual reserve fund. Of the remainder, one half is to go to the firm and the other half is to be divided among the men according to their wages earned. Whether the plan will be accepted or whether the men will have some unfortunate squabble remains to be seen, but they will not be alive to their own interests if they find fault with offers like the above.

THE COMMERCIAL VALUE OF ORIENTAL LANGUAGES.

The Imperial Institute has been the means of establishing a "School for Modern Oriental Studies" in London. Some few of the Eastern languages have already been taught at University College and King's College, London, and arrangements have now been completed with these two colleges by which thorough instruction can be given in twenty of the principal Oriental languages. On the 11th inst., Professor Max Müller delivered an inaugural address of the school, at the Royal Institution, to a large and influential audience. After referring to what had been done in France, Russia, Germany, and Austria-Hungary, the Professor showed the grave importance of the study of the modern Oriental languages from political, diplomatic, and commercial points of view. With regard to the value which this school would have to the vast commercial interests of this country, we may remember that England rules over nearly 300 millions of people who speak Oriental languages, and she probably supplies the markets of nearly 1,000 millions of the people of the East. To say the least, it more convenient for many reasons that the sellers of goods should be able to speak the languages of possible customers, and therefore the commercial houses and the nations who go in for this class of study are, in the very nature of things, the most likely to succeed in their transactions. But whether it is better to educate a potential business man or commercial traveller at a school for languages, than to send an enterprising man to a distant country where he will have the chance of picking up the native tongue, is quite another thing. We all know that a man who learns French and German at college, and then goes to France and Germany, generally cuts a sorry figure. There is another phase of the subject which we might mention. Germans seem readier at picking up a foreign language than the English, and at first sight they therefore appear to have a better chance of business with these nations. There is a counterbalancing advantage on the side of the Englishman, and that is, the general superiority of the goods he offers. As long as this high character is maintained, so long will the disadvantage of his ignorance of native languages be a less felt drawback to his success.

A NEW TELEMETER.

A very ingenious telemeter, consisting of two pairs of coils forming a sort of induction balance, has lately been brought out. Two instruments like Professor Hughes' sonometer are used. An intermittent current is sent through the home and the distant fixed coils, and a telephone circuit is led through the home and distant movable coil. The home movable coil is turned till there is silence in the telephone, and the position of the distant coil is then known. It may be suggested that if the alternating or intermittent current could be made powerful enough and the telephone removed, the home movable coil, if free to move, would take up the same position as the distant coil—that is to say, it would set itself so that the mutual induction in the two pairs of coils balanced. This may some day be useful where alternating currents are available.

EXHIBITIONS AND THEIR TENDENCIES.

Of late years there has been an epidemic of Exhibitions. South Kensington for several seasons monopolised most attention, but in addition there have been many subsidiary shows. Most have been unimportant, with the exception of Manchester, Glasgow, and Paris, but the smaller kind still continue to crop up. There is no doubt that in very many cases the industrial sections are completely overshadowed by the attractions of switchbacks, toboggans, and sundry other popular amusements. A financial contemporary makes a very good suggestion in this connection, to the effect that the red-herring of terming such enterprises "Exhibitions" might be dispensed with, and that a speculator of enterprise might find it remunerative to start a show without any apology for exhibits, and have merely a well-laid-out site, with good bands and illuminated fountains, which have been found so attractive ever since the late Sir F. Bolton hit on the idea. This proposition, if carried out, would at least give some paying work for one or more of our electrical firms.

THE BRAZILIAN RUBBER MONOPOLY.

The Government of Para has recently granted to a native company the monopoly of the trade of the province, which has induced the American and French trades to protest against this unfair treatment of foreign firms, and we understand that the more important English houses are also taking a similar step. Although rubber is obtained from many tropical countries, and considerable quantities are exported from other parts of Brazil, and especially from St. Salvador, the best sort of caoutchouc is obtained from the province of Para, while inferior qualities are derived from the artocarp trees of the Gulf of Mexico and of Guatemala, and a small percentage of the supply of the better quality is contributed by the West Coast of Africa and Sumatra. The annual import from all sources to England amounts to about 11,000 tons, and of this quantity it is estimated more than half is derived from Para. This total by no means represents the extent of the industry in Brazil, as during the last year no less than 16,000 tons of rubber were shipped to other countries, of which about one-half was taken by the United States. It will be seen, therefore, that the threatened monopoly of this product by the Para Government may seriously effect the rubber trade of this and other countries, and it is thought that the move may increase the price of the raw product by 10–12 per cent. of the present quotations. It is to be hoped that the combination will stimulate the other countries to develop their resources, and in Borneo, where the *Urceola elasticæ* is known to yield a very satisfactory product, there seems to be an opening for further enterprise in this direction.

20855. Allaire & Gautier ... Rotary engine.
20857. Bracebridge, J. E. C.... Mounting heavy guns.

30th December, 1889.

20860. Thwaite, B. H. ..... Open hearth furnace.
20861. Hollanders & Leather Railway coupling.
20865. Patterson & Patterson Drilling rock.
20866. Hollingworth, E. ..... Looms.
20871. Allen, J. J. ..... Feeding printing machines.
20872. Longworth, J. ..... Pistons and cylinders.
20884. Cheetham, J. ..... Mules.
20886. Wilson, G. ..... Construction of wheel tyres.
20887. Fox, S ..... Railway underframes.
20888. Fox, S. ..... Bending channel iron.
20892. Abel, C. D. ..... Gas engines (*Gas Motoren Fabrik Deutz*).
20895. Watson, J. W. ..... Signalling at sea.
20900. Evans, T. ..... Steam motor, &c.
20904. Cooper, H. J. ..... Sifting apparatus.
20906. Lake, H. H. ..... Sewing machines (*Amborn*).

31st December, 1889.

20910. Yeo, W. B. ..... Compound engines.
20912. Mills, J. ..... Water tube steam generators.
20920. Nixon, R. B. ..... Elevators for raising grain.
20922. Stephenson, H. ..... Grinding mills.
20926. McDowell-Guajardo, J. A. ..... Spinning frames.
20928. Fitzpatrick, H. D. ..... Furnace grate bars (*Improved Zig-zag Grate Bar Company*).
20930. Hargreaves, W. ..... "Shaking machines" for cotton waste.
20931. Vos, J. E. ..... Shaping metal (*Weed*).
20935. Taylor, M. ..... Tramway couplings.
20937. Froggatt, C. ..... Fur cleaning machines.
20941. Talbot, J. S. ..... Machine for digging land.
20945. Helmore, F. G. ..... Hydraulic waterer and cleaner.
20952. Zerbe, J. A. ..... Transmitting motion.
20954. Wright, J. ..... Distilling or concentrating liquids.
20958. Haddan, R. ..... Mules (*Jaudeau*).
20959. Gibson, W. P. ..... Elevators.
20960. Gibson, W. P. ..... Safety appliances for elevators.
20966. Lake, H. H. ..... Dies for rolled forgings (*Gould Rolling Machine Company*).
20967. Lake, H. H. ..... Metal pipes (*Bayles*).
20968. Odell, J. B. ..... Type-setting machines.
20970. Pallister, E. ..... Projectiles.
20975. Rysselberghe, F. ..... Hydraulic motors.
20977. Johnson, W. ..... Drilling rock.
20978. Browning, J. ..... Machines for spinning metals.
20979. Beesley, F. ..... Ejector for breakdown guns.
20985. Woodroffe & Pendlebury ..... Mowing and reaping machines.
20986. Lake, H. H. ..... Furnaces (*Cornell*).
20988. Clarke, J. A. ..... Compound engines.
20989. Holmes, J. A. ..... Lubricators.
20990. Hussey & Hatch ..... Heating coils.
20992. Woodall, A. H. ..... Type-writing machines.

1st January, 1890.

3. De Negri, C. ..... Knitting machines.
9. Fisher & Richards ..... Slide valves.
10. Fisher & Richards ..... Controlling main engines.
11. Sample & Dick ..... Sea anchors.
13. Tolson & Tolson ..... Furnaces.
18. Craven, R. E. P. ..... Underframes of rolling stock.
20. Palmer, J. R. ..... Machine for cutting, grinding, and polishing glass.
21. Angus, R. ..... Apparatus for washing ores.
24. Olney, T. C. ..... Safety valves.
28. Cresswell & Heslop... Feeding printing presses.
32. Koch, P. ..... Machinery for facing screw-nuts.
38. Cooke, F. ..... Lubricators.

2nd January, 1890.

45. Ragg, A. E. ..... Drills for sowing seeds, &c.
47. Mason, W. F. ..... Furnaces.
49. McDonnell, J. ..... Lubricator.
54. Boult, A. J. ..... Pneumatic guns (*Eichbaum*).
61. Quick, G. ..... Ordnance.
62. Quick, G. ..... Breech mechanism for ordnance.
69. Bott, G. H. ..... Mechanism for starting vehicles.
73. Wilson, J. A. ..... Knitting machines.
74. Williams, R. H. ..... Ploughs.
75. Cooper, Roe, & Cooper Knitting machinery.
83. Williams, J. G. ..... Steam boilers.

3rd January, 1890.

105. Fraser, J. ..... Dynamometer.
106. Pilot, W. ..... Lubricators.
111. Butterworth & Butterworth ..... Machinery for straightening piece fabrics.
120. Jacob, F. W. ..... Rotary pumps.
122. Edwards, E. ..... Drilling rock (*Terp*).
125. Haddan, R. ..... Guns (*Pignat*).
127. Younger, A. ..... Regenerative heating furnaces. (5th June, 1889.)
131. Wells, C. ..... Steam engines.
132. Mewburn, J. C. ..... Compressed air motors (*Proell & Kummer & Co.*).
133. Gastrell, J. P. H. ..... Transmitting power.
136. Boyd, H. P. ..... Dies for forging screw threads.
140. Sleep & Sleep ..... Ploughs.

4th January, 1890.

145. Hutchison, M. ..... Steam boilers.
147. Newall, G. W. ..... Quadruple expansion engines.
156. Claridge, J. W. ..... Feeding furnaces with fuel.
157. Tillotson, M. ..... Couplings for shafts.
160. Hughes, G. ..... Steering gear.
161. Foden & Foden ..... Valves for pumping engines (*Attenbrow & Barratt*).
169. Robinson & Jackson ... Brick machines.
170. Anderton & Barlow... Screw-threaded spindles.
172. Finley, C. A. ..... Railway signal.
175. Mannesmann, R. ..... Electrical wires.
176. Imray, H. ..... Drawing metal tubes (*Moerchen*).
177. Johnson, S. O. ..... Steam jet pumps.
181. Shorter, F. ..... Locomotives.
185. Vogelsang, A. ..... Screw propellers.
187. Voilin, J. ..... Magazine firearms.
190. Talbot & Hardcastle Ingots of steel.
191. Talbot & Hardcastle Tubular ingots, &c.

ELECTRICITY.

27th December, 1889.

20797. Strode & Gill ..... Fittings for electric light.

28th December, 1889.

20856. FitzGerald & Hough... Voltaic batteries.

30th December, 1889.

20885. Price, H. S. ..... Fittings for electric lamps.

31st December, 1889.

20911. Woolf, A. E. ..... Storage batteries.
20918. Thompson, W. P. ..... Electric currents (*Stanley*).
20955. Wood, J. J. ..... Dynamo-electric machines.
20974. Rysselberghe, F. ..... Hydro-electric distribution.
20991. Jensen & Jensen..... Electric bells.

1st January, 1890.

29. Dardier, S. V. ..... Electrical deposition of metals.
42. Smith, W. S. ..... Electric cables.

2nd January, 1890.

58. Gardner, H. ..... Incandescent electric lamps (*Reid*).

3rd January, 1890.

113. Moseley, W. ..... Electric meters.
135. Atkinson, L. B. ..... Alternate current motors.

4th January, 1890.

180. Edwards, E. ..... Automatic telegraphs (*Cassalette & Kunhardt*).

CHEMISTRY.

27th December, 1889.

20787. Longshaw, J. ..... Treatment of spent acid.

30th December, 1889.

20862. Smith & Cresswell ... Nitrate of ammonia and bicarbonate of soda.

31st December, 1889.

20908. Mason, Warren, & Warren ..... Recovering soda.
20980-1. Newton, H. E. ..... Manufacturing gas (*Fuel, Gas, and Light Improvement Co.*).

1st January, 1890.

16. Smillie, J. ..... Preventing action of water on lead.
39. Friswell, R. J. ..... Dyestuffs.
44. Ball, S. J. ..... Charging gas retorts.

2nd January, 1890.

67. Parker, T. ..... Distillation of coal, &c.
70. Bang & Ruffin ..... Separating tin.
71. Bischof, G. ..... White lead.

3rd January, 1890.

128. Bang & Ruffin ..... Tinplates.
134. Friswell & Green ..... Colouring matters.

4th January, 1890.

149. Guthrie, H. ..... Treating sewage.
178. Richm, P. ..... Separating phenol and cresol from creasote.

MISCELLANEOUS.

27th December, 1889.

20802. Mills, C. K. ..... Regenerative gas lamps (*De Roest d'Alkenade*).

28th December, 1889.

20817. Smith & Sutcliffe..... Shuttles.
20848. Smith, A. ..... Artificial stone.
20850. Horn, W. W. ..... Coupling pipes (*Hattery & Van Liew*).
20851. Horn, W. W. ..... Nut lock (*Leep*).
20858. Bennett, W. A. ..... Packing for stuffing boxes, &c.

30th December, 1889.

20891. Punter, J. ..... Compensating expansion signal pulls.
20897. Bull, J. C. ..... Cartridges.

31st December, 1889.

20934. Bean, G. H. ..... Perpetual motion.
20936. Pinagel, L. ..... Freeing wool from grease.
20944. Vorwieger, F. E. ..... Shuttles.
20948. Reay & Co. ..... Filtering apparatus.
20969. Tighe, C. ..... Fog signalling.

1st January, 1890.

27. Clark, A. M. ..... Distilling crude petroleum (*Dull*)

2nd January, 1890.

82. Slingsby, R. ..... Magnesium lamps.

3rd January, 1890.

97. Walker, M. ..... Ventilators.
142. Chevallot, E. ..... Dyeing and waterproofing textile fabrics.

4th January, 1890.

189. Bray, G. ..... Fire escape.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Raising or Forcing Liquids.—*L. & L. Kern, Edenkoben, Germany.*—The appliance is constructed for raising hot, strongly acid, alkaline or muddy liquids, and for forcing them into filter presses. Fig. 1 is a vertical section and Fig 2 an end elevation of the appliance. The appliance works on the principle of an injector. The body A of the apparatus is an oblong block of wood protected upon the outside by iron as shown. This body has a longitudinal bore J of concoidal shape. Into the inlet side of the body is fitted a steam nozzle B of lead or other suitable incorrodible material. The apparatus has also a radial suction hole, into which is fitted a metallic tube C. The flanges L and

M of the pipes D and E are packed with india-rubber rings F F, and pressed against the ends of the block A by discs G and bolts H. The apparatus is placed outside the liquid to be raised, and as near to it as convenient, in order to obtain the maximum effect. Claim: (1) An ejector or injector, chiefly consisting of a hollow block of wood, into which is fitted a steam nozzle of lead or other suitable material; (2) the combination of an injector body A with steam nozzle B, suction pipe C, steam pipe D, discharge pipe E, and means for securing the said pipes to the body A; (3) the combination of a filter press with an injector as described.—No. 1563. January 29th, 1889. 8*d*.

Thrashing Machines.—*J. Johnson, Tarvin, Cheshire.*—The inventor describes a method of collecting the straw into bundles of a predetermined weight as the straw leaves the thrashing machine. For this purpose a suitable form of weighing apparatus is attached to the end of the thrashing machine. The straw is delivered to this weighing apparatus, and as the amount reaches the weight determined on the apparatus overbalances and discharges the straw. The weighing apparatus consists of four platforms, which revolve upon a shaft fixed laterally in the rear of the thrashing machine. These platforms alternately assume positions for receiving the straw, and are held in such positions by spring catches. The catches are adjusted to retain each platform until the load of straw accumulates to the weight determined on, when the platform falls, revolving upon the shaft and discharging the straw. As the straw is delivered from the thrashing machine it is beaten down on to the platforms by a batten beater oscillated by a crank, &c., actuated by a pulley fixed to the shaker spindle. Claim: The improved method and apparatus for collecting the straw (as it comes from the shakers of a thrashing machine) on to rotating arms, which are retained from time to time by a spring sliding bolt or other suitable contrivance until the load of straw overcomes the pressure or holding power of the spring or withdraws the bolt to release the rotating arm, and thus deliver the straw in uniform quantities.—No. 18300. December 14th, 1888. 6*d*.

Printing Machines.—*W. Rouse, Nottingham.*—The object of this invention is to put a lateral tension upon the paper in order to remove creases, &c. This the inventor does by the use of two rollers placed to revolve upon the edges of the paper with their axes in the same plane, but at an angle to each other. When working, the inclination of the rollers would be to travel towards the centre of the machine, but being fixed in stationary bearings they draw the paper out towards the edges of the printing machine cylinder. The rollers are mounted on frames which have both lateral and angular adjustments. These frames are mounted upon a slotted bar, and the whole is actuated by a cam motion, such that at each revolution of the cylinder the rollers are pressed against the edges of the paper. Claims: (1) The use of parallel or conical rollers, or wheels, in a straight line or at angles to the cylinder of the printing machine for the purpose described; (2) the use of adjustable bearings as herein described for the purpose of putting the rollers at any angle required.—No. 1474. January 28th, 1889. 6*d*.

Gaseous Fuel Furnaces.—*C. Imray, London.* (*E. R. Ware, Chicago, U.S.A.*).—Fig. 1 is a sectional elevation of the apparatus including the boiler, and Fig. 2 a sectional plan showing the gaseous fuel burner. A is an enclosing wall or casing, preferably of brick, with a suitable top forming an enclosed chamber. Within this casing is the boiler C, having an inner and outer shell, between which there is a water space C¹, the whole being of dome shape. D D is a fuel supply pipe projecting through the wall and through a semi-circular notch in the lower part of the boiler. The combustion of the gases takes place in the fire-pot E F, and from a specially constructed burner of the Bunsen type. The walls of the firebox are water channels, which communicate with the main body of boiler by the pipes M and N. H is the inlet pipe for the steam or water as the case may be, the outlet

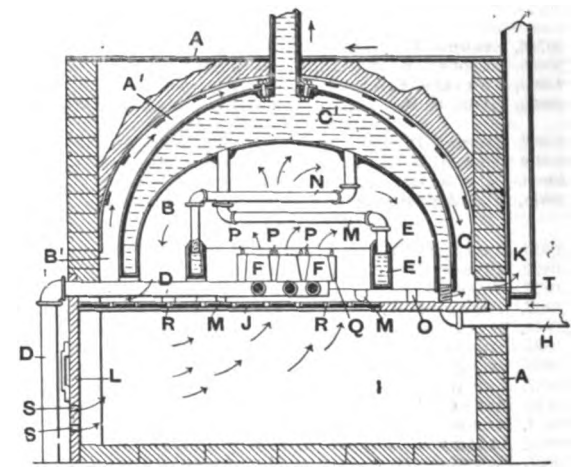

FIG. 1.

pipe being at the extreme top of the boiler. Beneath the heating chamber is a space I separated from the chamber only by a perforated sheet. From this space I air for the purpose of combustion is supplied through the holes in the perforated sheet. From the above description it may be understood that, when the fuel is ignited, the products of combustion will pass up through the passages which are formed by the fire-pot, and are surrounded by water spaces, thence into the upper central part of the inner heating chamber, which is formed by the inner wall of the dome-shaped boiler. From there it passes downwards, under the lower edge of the boiler, into the outer heating chamber constituted by the outer case of the boiler and the inner surface of the casing A. During this movement of the products of combustion, their heat will be in great measure absorbed by the boiler and its contents, the waste products of combustion passing out through the final out-

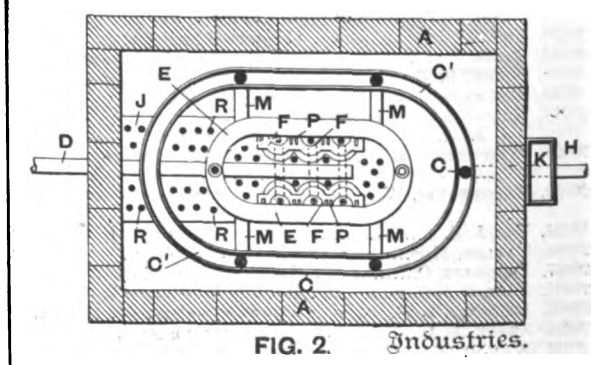

FIG. 2. Industries.

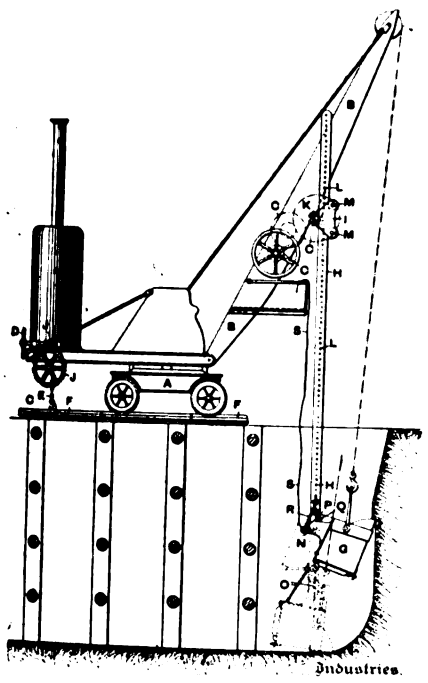

let T. Claims: (1) The combination in a heater of a dome-shaped combustion chamber, having a substantially continuous inner surface, a fluid fuel supply pipe, an inlet for the admission of air to the combustion chamber, and an outlet for the waste products of combustion, said outlet being located below the plane of ignition of fuel, whereby the waste products of combustion are compelled to pass out below the plane of ignition of fuel; (2) the combination in a heater of a combustion chamber, a boiler surrounding the combustion chamber, a heating chamber outside of the boiler, a fluid supply pipe, an air inlet and an outlet for the waste products of combustion, said outlet being located below the plane of ignition of fuel; (3) the combination in a heater of a boiler provided within an inner heating chamber, a heating chamber outside of the boiler, a passage for the products of combustion from the lower part of the inner chamber to the outer chamber, a fluid fuel supply opening into the inner chamber, an inlet for the admission of air to the inner chamber, and a final outlet for the waste products of combustion, said final outlet being located on a level or thereabouts with the point at which ignition of the fuel occurs; (4) in a heater, the combination with the boiler support and fluid supply, the dome-shaped boiler provided with an internal combustion chamber, having a substantially continuous inner surface, and arranged with its lower edge

Digitized by Google

above the boiler support, of the enclosing casing, whereby there are formed two chambers below the boiler for the products of combustion from the combustion chamber.—No. 15,043. September 24th, 1889. 8*d*.

APPARATUS FOR REMOVING SCALE FROM BOILERS.—*R. Elliott, Newcastle-on-Tyne.*—The apparatus constituting this invention is designed for removing scale from the internal parts of boilers which are difficult of access or quite inaccessible to ordinary scaling tools. The apparatus consists of a chipping hammer head secured to a lever, which is pivoted in a frame and made to vibrate by a rod attached to the other end of the lever. The frame occupies a small space, and can be inserted in narrow channels or pipes by a rod connected to it. When at work a part of the frame rests against one side of the channel or pipe, whilst the chipping hammer is made to operate upon the opposite side by working the rod attached to the lever. Claim: The combination of parts constituting the improved apparatus for removing scale from the internal surfaces of steam boilers, as described.—No. 17379. November 2nd, 1889. 8*d*.

EXCAVATING CRANES.—*T. Whitaker, Horsforth, Leeds.*—These improvements are primarily designed to perfect the apparatus for excavating to a lower level than that on which the apparatus stands, and to facilitate the removal of the track from the behind to the front as the work proceeds. Referring to the illustration, A is the carriage and B the jib of an ordinary portable crane. To the tail of the crane is affixed transversely a drum operated by a hand-wheel D and worm and worm-wheel J. The drum carries two hoisting chains E terminating in hooks C which engage in a part of the track when it is to be removed. When the track has been raised by the hooks the crane is revolved upon its centre pivot and the track deposited in the front. The apparatus shown is particularly designed for excavating sewers. The scoop or bucket G is pivoted at the end of the arm H on the pin or pivot N. The bucket is held in a position beyond the end of the arm H by a small chain O, one end of which is attached to the bucket and the other end engages with a small catch P pivoted to the arm H. The catch P is held when the bucket is in the position shown in dotted lines by the bar or lever R, which can be withdrawn by the cord S. The arm H is formed with a series of teeth at each side which form racks L which gear with the wheels as shown. A small cradle M pivoted to the shaft K holds the racks in gear with the pinions. The bucket is held in the position shown in

dotted lines until it reaches the bottom of the excavation, when the catch P is released, and as the operations begin by hauling in the chain the bucket is pulled forward on its pivot N until it assumes the position shown in full lines at about right angles to its previous position. It is here stopped by a stop Q against the rod or arm H. As the excavation proceeds, the shaft H is permitted to pass in through the cradle M at a rate adjustable by a suitably contrived brake, thus causing the bucket to assume any position in its upward movement. The rack and wheels can be worked by a hand wheel, and thus the bucket made to assume any position for the purpose of discharge, &c. Claims: (1) The combination with a crane-navvy or ordinary portable crane of an auxiliary drum and winding chain affixed to the tail of the crane; (2) a bucket arm or excavating attachment for an ordinary portable crane having the bucket pivoted or hinged to the end thereof so as to excavate in a straight instead of a curved path; (3) in a crane-navvy such as described in my former patents Nos. 16701 of 1886 and 2757 of 1887 a bucket arm having a longitudinal slide or slot, in which the pivot rests or slides, in combination with the rack, wheels, and hand wheel.—No. 946. January 18th, 1889. 8*d*.

CENTRIFUGAL PUMPS AND FANS.—*H. A. Entwisle, Bolton.*—Certain improvements are here described to minimise the retarding action of the liquid or air in delivery. The revolving disc of the pump, with its circular or segmental blades, is enclosed between two cheeks bolted together and provided with inlet and outlet passages. The inlet passage is divided into two thoroughfares, one on each side, to allow of the liquid being supplied to the centre of the revolving wheel. These thoroughfares are each constructed of a spiral form to direct the liquid to the pump in a circular manner corresponding with the direction of the travel or circular motion of the revolving disc, thereby reducing the retarding action of the liquid. The revolving disc or wheel, with the circular or segmental blades, is mounted on a spindle or shaft held in suitable bearings and stuffing boxes on the sides of the pump. To reduce the back pressure on the blades they are provided near their outer extremity with curved projections, which are turned to the internal diameter of the casing. As soon as each of these projections pass the point dividing the outlet from the central portion of the pump the bulk of the blade is removed from the pressure of the liquid in the outlet pipe. Claims: (1) In centrifugal pumps and fans the use, construction, and arrangement of the spiral inlet passages as described for the purpose specified; (2) in centrifugal pumps and fans the use of the projections in combination with the blades or vanes for the purpose specified.—No. 1723. January 31st, 1889. 8*d*.

GRAIN CONVEYERS.—*J. Stevenson, London.*—This invention consists of an improved construction of conveyers, in which a flat or attenuated spiral is employed, attached by means of ordinary paddle-worm flights to a centre spindle. The periphery of the spiral is preferably thin, thickening towards the base, and may be formed of a steel bar. One claim is made.—No. 552. January 11th, 1889. 6*d*.

BRICK AND TILE MACHINES.—*L. B. Kennedy, St. Louis, U.S.A.*—Part of a machine is here illustrated, showing a system of levers for compressing and forming bricks. Bell-cranked levers C and D are pivoted upon the framing of the machine and operated by toggle levers K. The toggle levers K are worked by a pitman M and cam plate R. When the cam plate R is revolved upon the shaft L the cam S moves against the friction roll W and draws the pitman back. This motion straightens the toggles, as shown in Fig. 1, and raises the outer

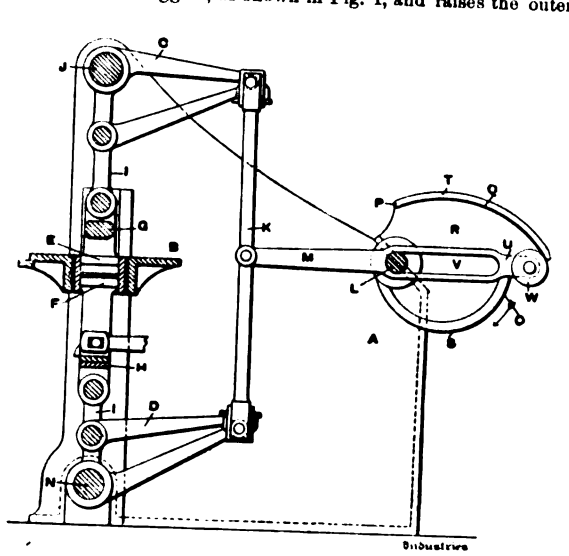

FIG. 1.

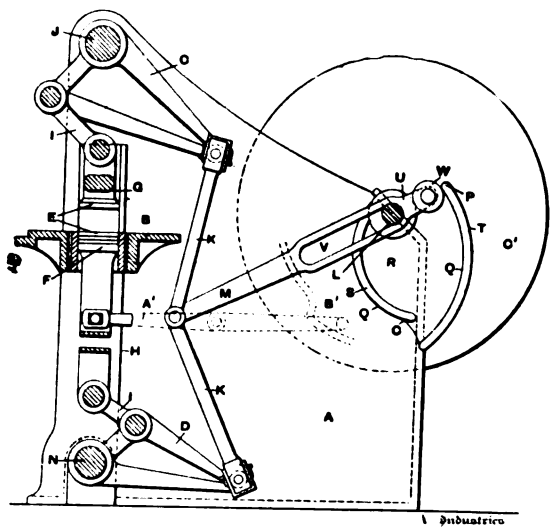
ends of the bell-crank levers, bringing the plungers E and F toward each other, and exerting the proper pressure on the clay to form a perfect and solid brick. A continued rotary motion of the cam plate now brings the friction wheel against the cam T, and causes the pitman to return to its former position, and at the same time eject the newly formed brick, as shown in Fig. 2. Claims: (1) In a brick machine of the character described, and the compression plungers of which are attached and operated by



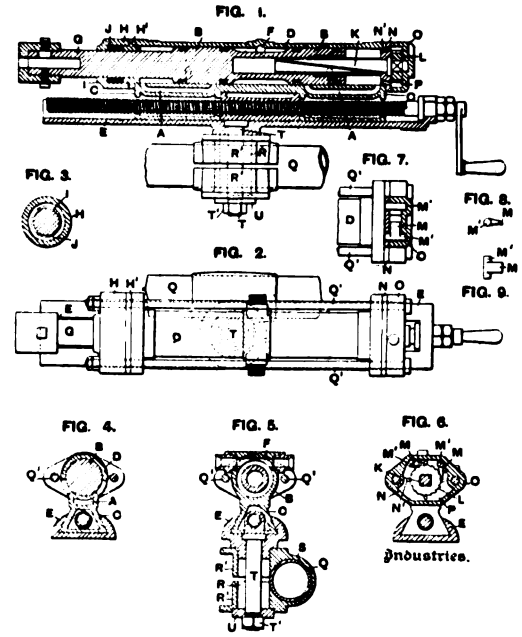


FIG. 2.

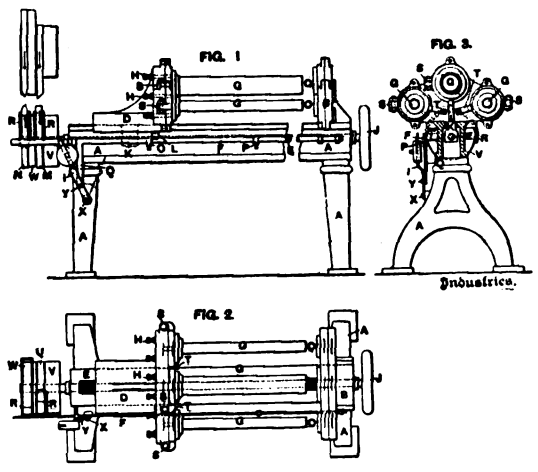
bell-crank levers, the said levers connected at their outer ends by toggle levers operated from a continuously rotated shaft; (2) in a brick machine, the angle or bell-crank levers C and D pivoted in the sides of the machine, said levers being connected to the plungers by means of links or knuckle-joints, which yield in opposite directions, the outer ends of the angle or bell-crank levers being connected by toggle levers operated from a continuously revolving shaft.—No. 17,121. October 29th, 1889. 6*d*.

SEPARATING CYLINDERS FOR GRAIN.—*P. van Gelder, Sowerby Bridge, Yorkshire.*—In separating and sieving apparatus of the description to which this invention relates, the material to be treated is kept in motion within a revolving or oscillating cylinder, which is perforated in a suitable manner. The dust and smaller grains pass through to the exterior of the cylinder, but after a short time of working the perforations become blocked by the grain, &c. To remove this blocking is the object of the present invention. The object is attained by the use of a row of wooden fingers, whose tips rest upon the cylinder in a line with its axis. The fingers are pressed against the cylinder with a yielding pressure, and so push the material wedged in the perforations back into the cylinder. To assist the fingers, radial brushes or whisks may be mounted inside the cylinders, to brush against its surface. Claims: (1) In combination with a sieving or separating cylinder for grain, seeds, or the like, a series of fingers spring pivoted or otherwise flexibly mounted side by side in proximity to the cylinder, and having their tips bearing with a yielding pressure upon the surface thereof; (2) in combination with a sieving or separating cylinder for grain, seeds, and the like, an inclined plate or series of inclined fingers located within said cylinder in such a position that material which has been carried by the rotation of the cylinder to a certain point is on falling backwards, led by said plate to the lower or comparatively unoccupied portion of the cylinder, instead of being permitted to fall again on to the material immediately below it.—No. 2611. February 14th, 1889. 8*d*.

SAFETY BRAKES FOR LIFTS, &c.—*C. Imray, London (A. Pifre, Paris).*—The safety brakes employed for the cages of lifts or mine shafts are usually so arranged that when the suspending rope or chain gives way, they act at once, gripping the guides and pressing against them with their full force. When an accident occurs during the descent of the cage, the stress resulting from stopping suddenly often deranges or fractures the brake mechanism. This is avoided in the present invention by causing the brake to act gradually and independently of the distance travelled by the lift. The brake is similar in shape to a blacksmith's tongs, whose jaws grip the side rails, and whose shanks are worked by springs. The springs act when the cable breaks, and cause the jaws of the brake to grip the rails, but the action of the springs are retarded by means of a dash pot or air buffer. Five claims are made.—No. 2,579. November 8th, 1889. 8*d*.

ROCK BORING AND DRILLING MACHINES.—*J. E. Powell, R. J. Powell, & W. Whitaker, Wrexham, Denbigh.*—The object of this invention is to simplify the construction of compressed-air rock drills and to render them more efficient. Fig. 1 is a longitudinal section of the apparatus; Fig. 2 a plan; Figs. 3, 4, 5, and 6 cross sections upon various parts of the apparatus. Compressed air for working the machine is applied through the inlet F, and admitted to the ends of the piston B by the ports A. The ports are formed in the dovetailed piece C, and so are protected from accidental damage. The ports are also uniform, in order that the piston B may be reversed in its cylinder, to equalise the wear and so make the parts wear longer. The piston rod G is packed by metal collars I, which are pressed against the rod by an indiarubber collar J. The piston B is rotated in a well-known



manner by means of the twist bar K, ratchet wheel L, and pawls M, Figs. 1 and 6. In order to obtain additional air space without lengthening the cylinder, the chamber P is connected to the cylinder by the holes N¹. Claims: (1) In a rock-boring or drilling machine, forming the ports within the dovetailed slide; (2) in a rock-boring or drilling machine, the use of metallic rings formed in segments, in combination with indiarubber or other elastic rings, for producing an air-tight joint where the piston rod passes into the cylinder; (3) in a rock-boring or drilling machine of the kind herein described, constructing and arranging the pawls which operate in conjunction with the ratchet wheel for turning the cutter, so as to be supported on both sides; (4) a new kind of clip, in which a single bolt and nut serves to lock the stretcher bar to the rock-boring or drilling machine; (5) the improved clip; (6) the rock-boring or drilling machine as described.—No. 18,284. December 14th, 1888. 8*d*.

ROTARY ENGINES.—*H. H. Leigh, London. (P. E. Don & M. J. A. Don, Bordeaux).*—The rotary engine here described works expansively without the aid of valves. It consists simply of a cylinder with inlet and outlet ports cut longitudinally in its side and close together, in combination with a piston of the following construction. The piston is carried by a piston shaft passing through and supported by the two ends of the cylinder, and placed eccentrically to the centre of cylinder. The part of the piston rod within the cylinder is enlarged by a collar or sleeve of metal of sufficient thickness to touch the interior of the cylinder at its nearest point, which is between the exhaust and inlet ports, and thus causes a steam-tight joint between the two. Through the centre of the collar and piston is cut a longitudinal slot, to admit a flat and rectangular plate of metal which constitutes the piston. This plate of metal is free to slide in the slot, to permit it as it is revolved to assume a position in the piston rod such that its edges always touch the sides of the cylinder, forming a steam-tight partition longitudinally in it. Steam is admitted to the cylinder upon one side of the piston collar, and acts upon the surface of a small

Digitized by Google

portion of the sliding plate or piston protruding from the collar on that side. The piston and rod are thus caused to revolve, and in their movement more of the piston becomes exposed to the action of the steam until it reaches the position where the piston is in a line with the centres of the piston rod and the cylinder, and from there the surface again gradually decreases. The inlet port is placed so that the supply of steam is cut off by one edge of the piston after the other has travelled a certain distance, to use the steam expansively. Claim: In rotary engines a cylinder bored out to a closed symmetrical curve generated by the extremities of a right line of constant length compelled to pass through a point eccentric to the symmetrical axis so as to describe during a revolution a maximum and a minimum segment, in combination with a parallelopipedal piston adapted to exactly follow the path of the said right line, the generatrix of the said symmetrical curve.—No. .

Forming and Polishing Tubes.—*W. R. Comings, London.*—The process consists of the following operations:—First, in making the tubes according to this invention, the lapping or abutting edges of the materials are first bevelled. Then one or both of these edges are coated with a suitable cement or solder. The sheet material is then bent round a mandril of the proper diameter, which is then by suitable mechanism forced slowly through a heated die, which, acting by combined pressure and heat, causes the lapped edges of the material to become firmly cemented or welded together. After the mandril has forced the tube entirely through the die, its motion is reversed by suitable mechanism, and it returns at a quick speed, while the tube, catching against a shoulder or suitable grippers at the back of the die, is stripped off from the mandril and the process is recommenced. Or if it is desired to impart a high polish to the tube,

it is allowed to remain on the mandril till after the return stroke, the high speed of which imparts the extra finish desired; or it may be carried back and forward through the die any desired number of times, till the requisite surface has been obtained, when the stripping mechanism is thrown into operation and it is removed from the mandril. Fig. 1 is a side elevation of a three-mandril machine; Fig. 2 a plan of the same; Fig. 3 a sectional elevation of the end; Fig. 4 an end elevation; Fig. 5 a plan of the same; Fig. 6 a vertical section upon Fig. 4; and Fig. 7 a die formed of rolls. To one end of a bed plate A is bolted a strong bracket B adapted to support and hold the dies C at right angles to the length of the bed. The other end of the bed carries a sliding carriage D with a crosshead, which is at right angles to the bed and parallel with the die holding bracket B. The carriage D is driven backwards and forwards upon the bed by the screw E, which is itself driven by the belts M N. The belts M N are shifted by the adjustable tappets O P upon the rod F,

FIG. 6.

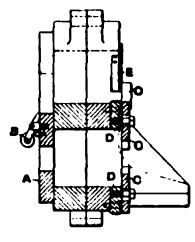


FIG. 4.

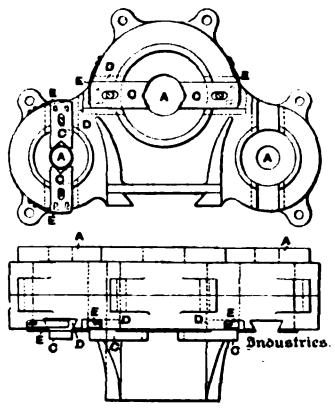

FIG. 7.

FIG. 5.

and thus the motion of the shaft is reversed. Heat is applied to the whole of the die, or an intense jet may be used simply at the point of lap. The operation of the machine is as follows:—The mandrils G G being stationary, the sheet material is bent round them and the cemented or soldered edges brought together and the machine started. The friction of the material upon the mandril carries it through the dies, while the heat and pressure causes the solder to melt and firmly unite the edges. When the tubes have been forced through the dies, the projection L on the carriage, acting upon the tappet P of the sliding rod F, shifts the belts and reverses the machine. As the mandrils return, the tube is stripped from the mandril by plates C (Fig. 4), held to their work by springs E. Claims: (1) The process of forming and polishing tubes which consists in first placing the material on a mandril having a reciprocating motion and then forcing it through a suitable die with or without an additional pressure roller for the seam; (2) the process of forming and polishing tubes which consists in first placing the material on a mandril having a reciprocating motion, and then forcing it through a suitable die with or without an additional pressure roller for the seam, and then automatically stripping it from the mandril; (3) in apparatus for forming or polishing tubes or the like the combination of a carriage carrying one or more mandrils with means for imparting a reciprocating motion thereto, and a bracket carrying dies corresponding with said mandril and adapted to polish the tube and strippers for stripping the tubes from said mandrils; (4) in apparatus for forming or polishing tubes or the like the combination with carriage D having projection L of a belt shifting rod F having adjustable stops *f f*¹ thereon, whereby the direction of travel of said carriage is reversed at any desired point; (5) in apparatus for forming or polishing tubes or the like the combination with the carriage D of the mandrils G hinged thereto and adjustable in relation therewith.—No. 17124. November 24th, 1889. 8*d*.

Mixing and Suction Valve.—*W. Fischer, Ludwigshafen-am-Rhein.*—The casing of this valve has two inlet and one outlet pipes, whose communication are controlled by means of a double-seated valve. The inlet pipes communicate to spaces arranged similarly to an ejector, one space surrounding the other in an annular form. A conical-shaped valve covers both outlets. When the valve is screwed off its seating the liquids flow in from both spaces, and that of the central space mixes with that from the annular. The central pipe may be constructed to adjust the area of the annular space, and so the proportion of the liquids. Claim: A mixing and suction valve, with two inlet passages and two tubular outlets, which latter have a valve seating formed at the ends, closable by a valve body common to both, and either the one slidable within the other or both fixed.—No. 9007. May 30th, 1889. 6d.

Vertical Boilers.—*J. H. Heck, Newport.*—The particulars of this invention are given in the following claims:—(1) The fitting of a tube or cylinder around the inside of all vertical boilers between the shell and the firebox or furnace, so as to divide the space between the sides of the firebox or furnace and the sides of the shell into two annular spaces, thereby increasing the circulation of the water in the boiler, through assisting the warmer and cooler currents of water and steam respectively to ascend and descend; (2) the fitting or perforation of holes in the said tube or cylinder in way of the manholes or hand holes in the shell, or of the hand holes opposite the cross-tubes of the firebox or furnace, so that the firebox, with its cross-tubes, can be properly scaled or cleaned; (3) the fitting of a bevelled or square angle covering plate to the end of the said tube or cylinder nearest the water level so as to stiffen the end of the said tube or cylinder, and to check any excessive upward movement of the water contained between the firebox or furnace side and the inner part of the said tube or cylinder.—No. 3478. February 27th, 1889. 6*d*.

ELECTRICITY.

Electric Lamp Holders.—*I. A. Timmis, London.*—The object of this invention is to increase the diffusion of the light of electric lamps. The lamp holder is constructed so that the lamp can be readily removed, and a reflector attached to the holder. The reflector is of circular form, and its under side convex and silvered. The edge is turned over downwards, and is either plain or serrated. It is fixed immediately over the lamp with its axis vertical. Claims: (1) The use of a convex silver glass reflector substantially as and for the purpose hereinbefore described; (2) the use of a holder constructed to hold the reflector close to the lamp bulb; (3) the use of a convex silvered glass reflector having a rim of clear or coloured glass.—No. 18010. November 12th, 1889. 6*d*.

Electric Railways.—*F. H. Reed, Jersey, & G. N. McKibbin, New York.*—This invention relates more particularly to rails and conduits upon that class of railways where electricity, derived from electrical conductors arranged in conduits along the line of railway, is employed as the motive power, &c. In carrying out the improvements it is preferred to lay on the cross-ties, under one of the track-rails, a continuous conduit constructed in two sections by a longitudinal division. On the top or crown of each of the halves or sections of the conduit is mounted one of the sections of a longitudinally divided track-rail. According to this construction there is an open slot or passage-way leading from the crown of the rail down into the conduit and extending along the centre track. In the conduits are arranged two conductors for forming the electrical circuit, electrical communication between them and the motor on the car being established and maintained by means of two conductors carried by the car and extending down into the conduits. The conductors on the car rub or roll against those in the conduits. This arrangement enables the conduits to be opened for inspection and repair without necessarily stopping the traffic on the road, inasmuch as the outer half or section of both the rail and the conduit may be removed and the inner halves or sections used as a temporary track for the wheels of the car. Seven claims are made for this form of conduit, for the methods of gaining access to it, and the means of draining it, &c.—No. 11615. July 20th, 1889. 8*d*.

CHEMISTRY.

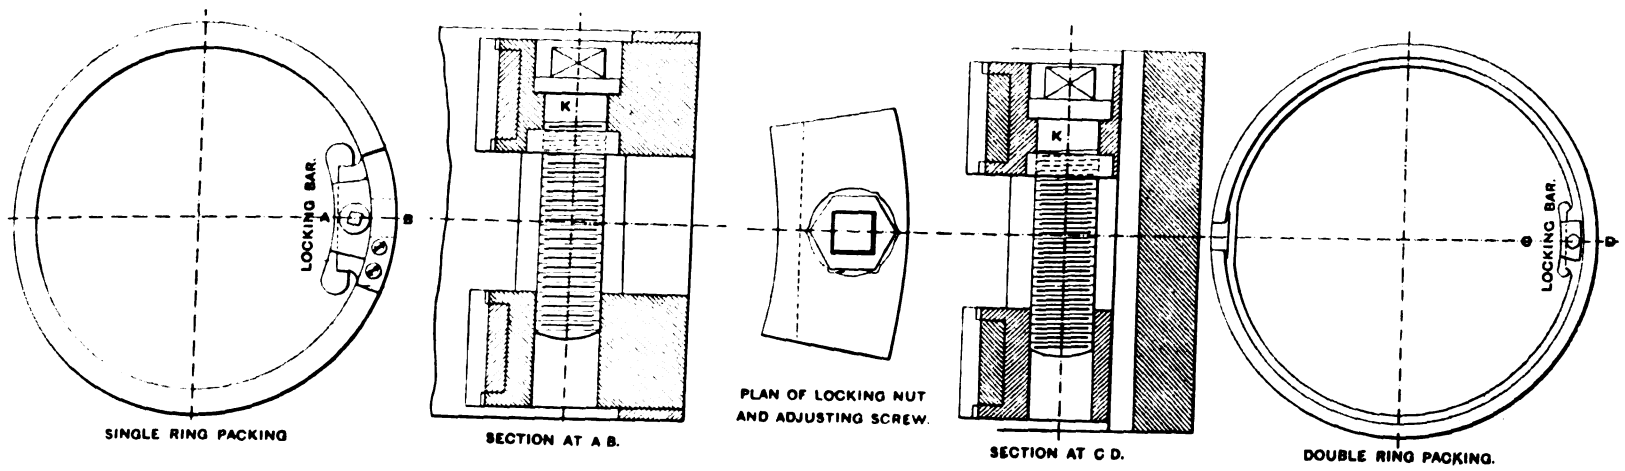
Sulphite Cellulose.—*F. Salomon, Berlin, and H. Brüngger, Leignitz, Germany.*—In a previous patent, No. 13396 of 1888, a method is described of protecting the apparatus used in the manufacture of cellulose from the destructive action of the sulphite lye, the method consisting in depositing a protective coating or film on the internal surface of the apparatus from the salts contained in the lye. In the present invention the protective coating is formed from salts other than those in the lye, such as sulphite of lime, sulphites of baryta, &c. Claims: (1) The method of producing a protective scale or coating on the bare internal wall or surface of a steel or iron boiler employed in the manufacture of sulphite cellulose as herein-above defined, which consists in introducing into the boiler, being preheated or not, a solution of gypsum or other salt or salts which, when heated, will produce on the said internal wall or surface a deposit such as will not be attacked by heated sulphite lye, and afterwards heating the boiler until the formation of the desired scale or coating is completed; (2) for the purpose of allowing escape of gases or vapours during the production of a protective scale or coating whether according to the patent No. 13396 of 1888 or according to claim 1 of this specification, providing the boiling apparatus with a valve; (3) for the boiling of sulphite substances the use of a boiler or vessel constructed of iron or steel, and having on its internal surface a protective coating or scale produced from a substance (such as a solution of gypsum or other salt or salts) other than the sulphite solution to be treated.—No. 18003. December 10th, 1888. 8*d*.

Bleaching Fabrics.—*M. Zingler, London.*—The fibre, or fabric, is cleansed by soaking for one hour or more in a diluted solution of commercial sulphuric acid of 5 per cent. strength, neutralised by liquid ammonia. Next 10lb. of gelatine, or glue, are dissolved in eight gallons of water, to which is added 1lb. of commercial sulphuric acid; 5lb. of glycerine and 2lb. of liquid ammonia are then added, and digested slowly at about 150° Fahrenheit till the ammonia is evaporated. To this solution 5lb. of oleic acid are added, which previously have been saponified in five gallons of water, with 1lb. or more of bicarbonate of potash. These gelatinous and oleaginous compounds are mixed till the whole mass is thoroughly amalgamated. About 400lb. of the fibre, or fabric, are placed in the mixture, and the temperature is maintained for several hours at about 130° Fahrenheit. When dry the fibre, or fabric, is put into a solution prepared by boiling 5lb. of oxide of zinc for ten minutes in five gallons of water, in which 1lb. of permanganate of potash has been previously dissolved. After soaking for a short time the fibre, or fabric, is hung up to dry and calendered. Two claims are made.—No. 84. January 2nd, 1889. 6*d*.

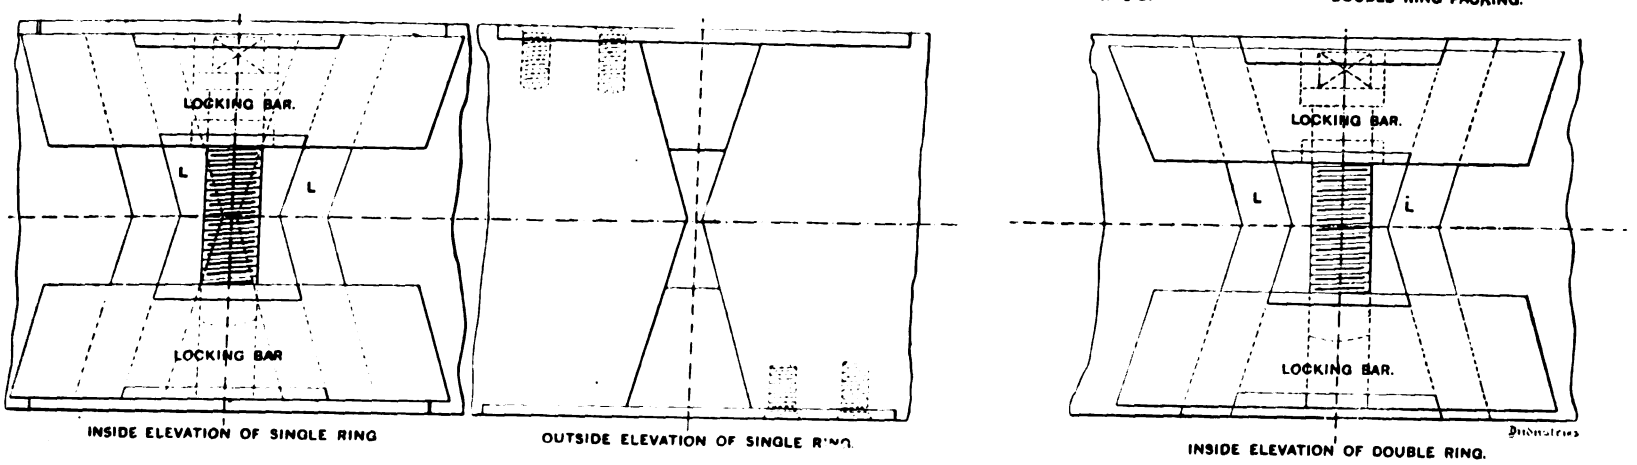
MISCELLANEOUS.

Speaking Tubes.—*H. Garrard & C. Clarke, London.*—The purpose of this invention is to produce the mouth-pieces of speaking tubes with permanently attached whistles and indicating apparatus. The method of constructing a mouth-piece as described will be seen from the following claims:—(1) A speaking-tube mouth-piece having a whistle permanently fitted therein in such a manner that it may automatically lodge in the air passage through the mouth-piece and be capable of being removed therefrom by pressure upon a button while using the tube for speaking purposes; (2) an indicator for speaking-tube mouth-pieces consisting of a hinged plate raised by a current of air through the speaking tube, passing out by a vent hole normally covered by the hinged plate; (3) in a speaking-tube mouth-piece with a permanent whistle arranged to be moved away from, and to return automatically into, the air passage, the employment of a light chain connecting the whistle with the hinged indicator-plate for returning the indicator plate to its normal position when the whistle is removed from the air passage to use the tube for speaking purposes.—No. 2390. February 11th, 1889. 6*d*.

Driving Belts.—*F. W. Barker, London. (F. W. Nichols & J. E. Ingersoll, Adrian, U.S.A.)*—The particulars of the invention are given in the following claim: A means for preventing the slipping of belts consisting of two belts placed one above the other on the pulleys so as to form a double belt, both belts mounted loosely on the pulleys so that the inner belt will sag as the belts pass over the pulleys, and the outer belt will sag as the belts pass under the pulleys.—No. 17835. November 8th, 1889. 6*d*.



Fire Escapes.—*J. C. Hudson, London.*—A conbination of a portable fire escape and hose cart is here described. The hose cart is of the usual form of hand cart, with wheelbarrow handles. On the front end of the box of the cart the ladder is hinged. The ladder is of the telescopic class, and when closed is about three times the length of the cart. To bring the escape into use, the end of the ladder nearest the hinge is depressed, and pinned to the handles of the cart in any desired inclined position. The lengths of ladders may then be drawn out by ropes, until the escape is of sufficient height. Claims: (1) The manner of constructing a light portable escape on a cart with box or frame, with fulcrum and handles, to be run horizontally, and raised vertically from this position by means of the said fulcrum and handles; (2) the manner of securing the escape in that position, with facilities for altering the angle; (3) means of detaching the ladder from the cart; (4) props and stays below the box, that can be slid out to touch the ground and prevent the ladder falling over when extended.—No. 2,841. February 18th, 1889. 8*d*.



Oil Lamps for Railway Carriages, &c.—*J. H. Ross & E. E. Atkins, Birmingham.*—This improvement consists in arranging and constructing the burner, chimney, and reservoir in such a manner that the light will be drawn down below the burner, thus obviating a dark shadow being thrown underneath the lamp. The reservoir is of annular form, and has its centre concentric with the centre of the lamp. The burner is of circular form, and the wicks are conducted from the reservoir to the burner by tubes which turn downwards as they approach the burner and cause the wicks to project nearly vertically downwards. When the burner is lighted, the flame surrounds the chimney, whose end projects through and below the circular burner, and by heating it causes an upward draft in the chimney and the flame to be drawn down round the bottom and up the chimney, whilst a supply of air is induced through holes provided for the purpose. Claims: (1) An annular oil reservoir situated above a reflector, and carrying an open framing to support a central chimney and a ring to support a deflector and glass globe; (2) from the oil reservoir three or more wick tubes, or groups of wick tubes, converging towards the centre so as to present around the outside of the base of the chimney a circular wick or a circular row of wicks having the ends directed downwards; (3) within the perforated lower end of the chimney a refractory cylinder within the wick in combination with an air deflector outside the wick; (4) the chimney fitted to slide upwards and to be retained in its raised position so as to give access for kindling the lamp; (5) a ring of asbestos or porous mineral supported in contact with the ends of the wicks, so as to form an incombustible terminal to the wick.—No. 2019. February 5th, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

DOWNIE'S IMPROVED PACKING RINGS.

WORK IN THE ROYAL DOCKYARDS DURING 1889.

Under the present Board of Admiralty speed and economy in ship construction have taken the place of slow and expensive building. This laudable change has been brought about in the first place by an extensive reorganisation of dockyard management and supervision, and in the second place through the increased facilities afforded by the introduction of modern machine tools. Recent extensions and improvements made in the workshops, and the more extensive use of labour-saving appliances, has enabled the dockyard workmen to compete favourably with private establishments in the output of work, both as regards time and cost. Ships to be built economically must be built rapidly, otherwise they become obselete, in the present progressive age, before being placed on actual service. In defending the policy of rapid construction, an eminent naval authority stated a short time ago that huge "battleships and fast cruisers will be wholly useless in action unless they have been already some time in commission, and their officers and crews have had ample time to become acquainted with them and their peculiarities."

Rapidity of construction has been the policy pursued in the royal dockyards under the present *régime* during the year which has just closed, and the energies of the various naval establishments have been fairly well taxed between building, repairing, and completing vessels for actual service. The total tonnage launched from the five dockyards exceeded 36,000 tons, consisting principally of first-class gunboats and cruisers.

Of these vessels the "Blake," launched at Chatham, and the "Vulcan," launched at Portsmouth, are the first of two new and distinct types of warship, each embodying many novelties and special features to meet the demands of modern naval warfare. When complete the "Blake," as a fighting machine, will be the most powerful of her class in the world. Between perpendiculars she measures 375ft., and in extreme breadth 65ft. With natural draught 13,000 i.h.p. is to be developed, and 20 knots is estimated as the corresponding speed, while under forced draught 22 knots is expected with 25,000 i.h.p. Including armament and equipment the total cost of the "Blake" is estimated at £430,000. The "Vulcan" is of an entirely different type of vessel, and has been specially constructed to meet the requirements brought about by the increased development of torpedo warfare. She measures 350ft. in length and 58ft. in breadth, and is expected, with her powerful engines, to realise 20 knots on the measured mile, and 18 knots continuous steaming at sea. A workshop and laboratory will form a part of her equipment, and a large supply of torpedoes and gear for submarine mining will also be carried. Provision is made for the transport of no fewer than nine second-class torpedo boats, and means requisite for their repair on board will be supplied. The "Vulcan" is being rapidly pushed forward to completion for service with the Mediterranean Fleet. Her estimated cost, including machine gun equipment, is £292,100.

The particulars of the vessels launched during the year at the respective dockyards are stated in the following table:—

Chatham Dockyard.

Name of Vessel.	Official Designation.	Displacement.	I.H.P.
Blake	First-class protected cruiser	9,000	20,000
Seagull	Torpedo gunboat	735	4,500
Salamander	,,	725	4,500
Skipjack	,,	735	4,500
Sheldrake	,,	735	4,500
		11,940	38,000

Portsmouth Dockyard.

Barham	Third-class protected cruiser	1,830	0,000
Barrosa	,,	1,580	3,000
Beagle	Sloop	1,170	2,000
Vulcan	Torpedo depot ship	6,620	12,000
		11,200	23,000

Pembroke Dockyard.

Blanche	Third-class protected cruiser	1,580	3,000
Blonde	,,	1,580	3,000
Redbreast	First-class gunboat	805	1,200
Redpole	,,	805	1,200
Magpie	,,	805	1,200
Widgeon	,,	805	1,200
		6,380	10,800

Devonport Dockyard.

Lapwing	First-class gunboat	805	1,200
Ringdove	,,	805	1,200
Spanker	Torpedo gunboat	735	4,500
Speedwell	,,	735	4,500
		3,080	11,400

Sheerness Dockyard.

Name of Vessel.	Official Designation.	Displacement.	I.H.P.
Barracouta	Third-class protected cruiser	1,580	3,000
Basilisk	Sloop	1,170	2,000
Goldfinch	First-class gunboat	805	1,200
		3,555	6,200

The "Gossamer" and "Gleaner," first-class torpedo gunboats, built at Sheerness, will be floated out of dock during the present month.

In addition to the completion and preparation of the large contingents of vessels of all types which took part in the summer manœuvres, several armour-clads have undergone a thorough overhaul and refit. Among others may be mentioned the "Thunderer" and "Glatton," which have been fitted with new machinery at Portsmouth Dockyard, and the "Superb," with new triple expansion engines at Chatham; also the "Alexandria" and "Nelson," with new boilers, &c., at the same establishment. When completed these vessels will form valuable additions to the navy, and will equal in many respects the more recent productions of battle-ships.

The keels of about twelve new vessels of various types were laid down during the year in the different establishments, including three large battle-ships of 14,150 tons displacement and 13,000 i.h.p., and a large cruiser of 7,350 tons.

DOWNIE'S IMPROVED PACKING RINGS.

In the form of packing ring which we illustrate above the packing is made with either single or double rings, and the partings or cuts are directly opposite each other. The adjusting screw K acts upon the V pads L and draws them together, thus expanding the ring. Moving with the pads there are the locking bars, which prevent the rings from being extended by the steam should it get inside, while the V pads resist all compression. By a slight movement of the adjusting screw the ring can be made to fill the chamber exactly, and any wear can be taken up in a few minutes. The rings have no flanges, and will thus expand equally, and as no springs are used, the chambers will not get barrel-shaped. When fitted as a piston it can be left to float or made solid by making a joint on the junk ring. For piston valves it is usual to fix the ring, and it thus becomes a solid piston possessing the advantages of being adjustable. The packing and ring have been designed by Mr. Thomas Downie, and are being placed on the market by Messrs. H. & C. Grayson, shipbuilders and engineers Liverpool.

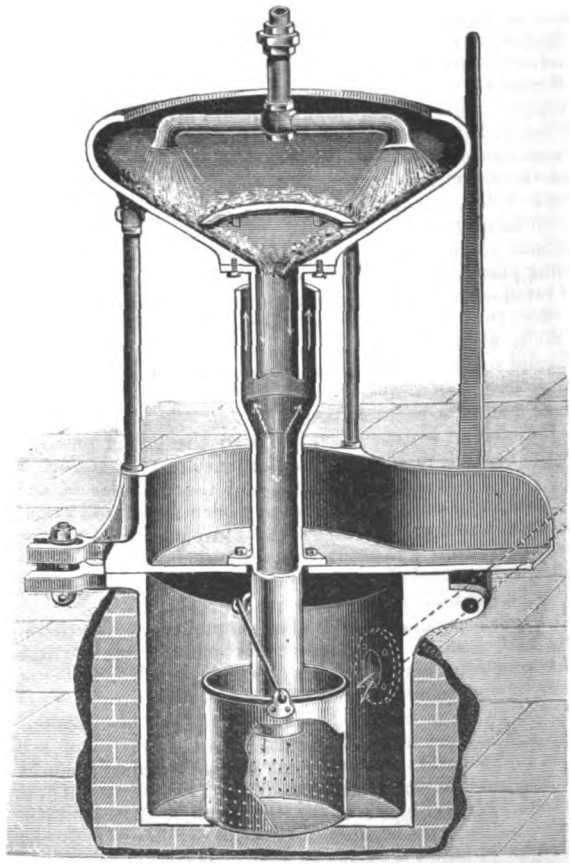
PATENT STATISTICS 1864-1889.

The last quarter of a century has witnessed a remarkable increase in the activity of inventors, which is mainly attributable to the improvements effected in the laws which relate to invention throughout the civilised world. The figures in the accompanying table denote the number of patents granted (including patents of addition, in each State, and where it has been possible to obtain the necessary data the numbers of applications and grants) for each year, and have been arranged for the purpose of comparison in parallel columns.



Broadly speaking, all patent systems may be divided into two classes, according as the official method of dealing with the application approximates to the American or English method. In the United States, as is well known, an application is subjected to a thorough investigation of its novelty by a careful comparison of the document with the specifications of a similar nature recorded in the office at Washington. The applicant may also be required to submit his invention to the ordeal of actual experiment in the laboratory to satisfy the examiner of its practicability. In spite, however, of the vigorous weeding out of worthless inventions consequent upon the application of so severe a combined test, the number of patents applied for (including re-issues and design patents) continued to increase until the year 1886, when the enormous total of 35,968 was reached, and a further increase is confidently predicted in the report of the United States Commissioner for the year 1887. The highest number of patents issued was in 1885, since which date a steady decrease has taken place, as may be seen on reference to the table. The total of patents issued for 1889 will be not less than 22,000, owing to the successful efforts made during the year to bring the work of the Office up to date; but with a normal working year it is probable that the tendency to decrease shown in recent years will reassert itself, and that the number of patents issued will bear an ever-decreasing proportion to that of the applications.

The fact that several countries, including Norway, Sweden, and Queensland, have in their recent legislation closely followed the German practice of examination for novelty, lends an additional interest to a perusal of the statistics of the German Patent Office since its establishment in 1877. The examination is an extension of the old Prussian system, which was based on a comparison of the application with the state of the art as disclosed in the Index of Specifications and Technical Periodicals contained in the library of the Commissioners of Patents in Berlin, and familiarly known in this country as *Schubarth's Repertorium*. The official practice, however, is entirely at variance with the more liberal traditions of the United States Patent Office, and the uncertainty which is experienced of an invention being treated on its merits, or of passing the frivolous objections which are constantly being raised, is the subject of much soreness and complaint amongst inventors, both here and on the Continent. It is not, therefore, surprising to find that the applications, which reached their maximum in 1886, have since shown a tendency to decline, while the grants have decreased at a more than proportionately rapid rate—the percentage having fallen from 59 per cent. in 1883 to 39 per cent. in 1887 and 1888.

The modifications introduced into the patent system of this country by the legislation of 1883–86 were generally in the direction of simplification of procedure and diminution of the initial cost of protection, and, with the exception of the suppression of the provisional document in cases where the application is not proceeded with, were not of fundamental importance. A careful study of the figures supports the view that the system of provisional protection supplies an equivalent for the official examination which prevails elsewhere. An inventor is enabled during the nine months to obtain a juster estimate of the market value of his invention than any official report could supply. On the other hand, if his search for prior anticipation has been defective, as it frequently is, he is enabled at any subsequent period during which his patent runs to disclaim the parts which have proved to be lacking in novelty. The same tendency which was observable in countries where a system of examination for novelty is in force appears to hold good here also, the percentage of patents sealed upon application having fallen from 69·1 per cent. in 1874 to 65 in 1883 and 52·1 in 1887. The rapid decrease since 1883 may be partly accounted for by the fact that owing to the non-publication of the provisional document an inventor feels at liberty to drop his application in order to make a second application at some more convenient time; but it is evident that the additions continuously made by inventors to the stock of public knowledge are steadily diminishing the chances of their successors in obtaining valid patents for their ideas. The truth of this deduction has been somewhat overlooked owing to the large increase in the numbers of applications, and the general prosperity of the patent industry, but it is one well worthy of the serious consideration of inventors. The remaining statistics call for no further comment, except that those for Russia do not include agricultural improvements, and that in some of the minor countries the figures must be taken as only approximately correct.

MACHINE FOR SEPARATING METALS FROM REFUSE.

We illustrate herewith a useful machine which has lately been invented by Mr. T. B. Sharp, of Birmingham, and placed on the market by Messrs. Fletcher Brothers, Borough Brassworks, Ashton-under-Lyne. It is intended for the separation of metals from earthy and other matters, and it may either be applied to the washing of ores, or for the recovery of brass turnings, &c., which accumulate on the floor of the machine shops. The earth or other refuse is fed into a hopper, in which a sparger rotates, as may be seen in the accompanying

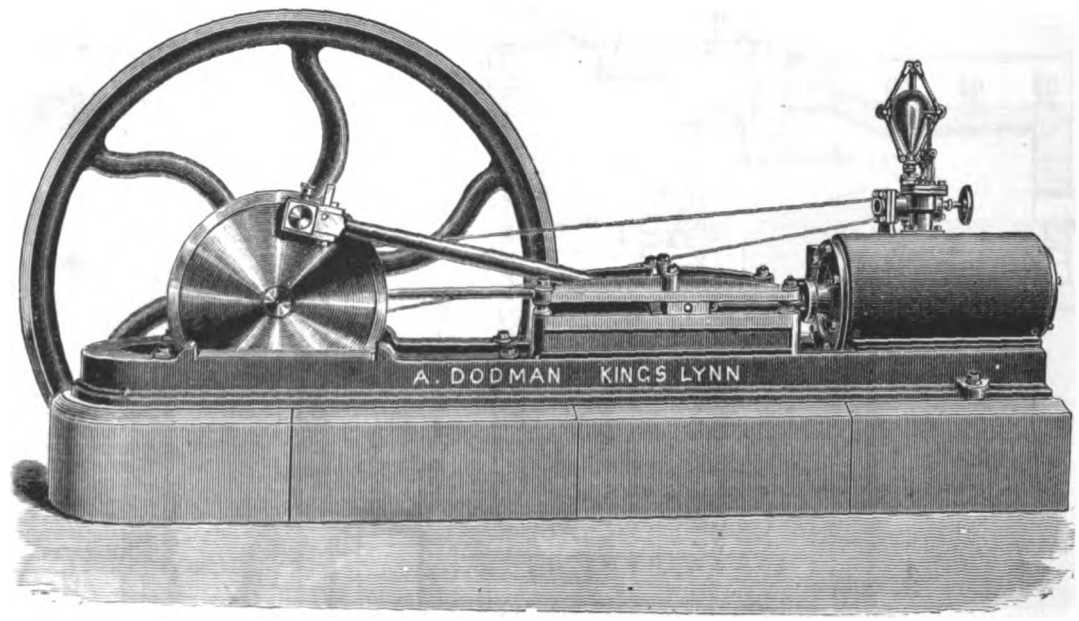
Digitized by Google

illustration. The spray of water whirls the particles round, and carries them down a feed pipe at the bottom. Here the stream, with the matter in suspension, meets a current of water which comes upwards through a similar pipe, and a sort of whirlpool is created. The upper end of the lower pipe is broadened and continued round the end of the upper feed pipe, and the water, together with the lighter particles, escapes through the annular space thus made. The heavier particles fall down the lower pipe and collect in the bucket at the bottom. The upward current of water enters the space in which the bucket is contained, and part of it passes through the perforations in the bottom of the bucket. The escaping water, together with the lighter particles, pass along a trough and over a weir. The function of the weir is to collect the suspended particles, and to afford the attendant an opportunity of ascertaining whether any metallic particles are coming over as well. The maximum specific gravity of the escaping particles is regulated by the head of the upward current of water.

We are informed that this apparatus has found great favour with a number of brass founders, and it is stated by them that they can wash as much machine-room refuse in four hours as used formerly to occupy a skilled washer a fortnight.

DODMAN'S HORIZONTAL ENGINE.

We illustrate herewith a neatly designed horizontal steam engine, which has been placed on the market by Mr. Alfred Dodman, engineer, King's Lynn. The cylinder is made of hard cast iron, and the bed is of box shape. The piston is of the Ramsbottom type, and the glands are bushed with gun metal. An equilibrium throttle valve and Porter's governor are fitted. The engine generally is finished in the best style, and its low price should give it a wide sale.



THE INSTITUTION OF CIVIL ENGINEERS.

At the seventh ordinary meeting of the session, on Tuesday, the 14th of January, the President, Sir John Coode, K.C.M.G., being in the chair, the paper read was on "Recent Dock Extensions at Liverpool, with a General Description of the Mersey Dock Estate, the Port of Liverpool, and the River Mersey," by Mr. George Fosbery Lyster, M.Inst.C.E.

The description of the dock extensions, which were more particularly the subject of this paper, was prefaced by some general remarks on the physical characteristics of the River Mersey and the trade of the Port of Liverpool. The geographical position of Liverpool, its unrivalled water frontage, and its proximity to the great manufacturing districts and to the coal and mineral fields of the north of England and Wales, could not fail to ensure its becoming a great port, and the result was seen in its continuous advance from the condition of a fishing village to that of one of the foremost seaports of the world. Its revenue at the beginning of this century, £23,380 on 450,060 tons, had increased, in 1889, to £990,000 from dues on 9,292,000 tons. The Mersey estuary was of peculiar form, roughly resembling a bottle, the wide upper estuary from Runcorn to Liverpool forming the body, and the six miles of narrows between Liverpool and Birkenhead the neck. The maintenance of the full capacity of the upper estuary was of vital importance to the port, and in this work the incessant changing of the low-water channel of the upper estuary was one of the prime factors. It was computed that on a spring-tide about 710,000,000 cubic yards, and on a neap-tide about 281,000,000 cubic yards, of water passed in and out at the mouth of the river at New Brighton. The ebb and flow of these vast quantities of water maintained channels through the wide sandbanks of Liverpool Bay. The principal channel was an excellent one as regarded width and direction; and as regarded depth, there was twice every twenty-four hours sufficient for the largest vessels, there being 10ft. of water on the bar at dead low-water of spring tides, giving 40ft. at high-water springs, and 30ft. at high-water neaps. Time was, however, now a most important element of successful trading, and the tendency was to increase the size of ships, so that a greater depth of water in the approaches to the Mersey was highly desirable, in order to avoid delay off the port. The attainment of such an end was, however, surrounded with physical and financial difficulties of no ordinary character; but the question was kept prominently in view, and the Mersey Docks and Harbour Board had recently decided to spend a certain amount of money on an experimental dredging of the bar by sand pumps. The first Liverpool Dock—the "Old Dock"—was constructed under powers obtained in the reign of Queen Anne, in 1708. The site was part of the old pool, a tidal creek on the right bank of the Mersey. This dock was the first wet-dock constructed in England, its area was four acres, and it had within it, on lowest neap-tides, 10ft. depth of water. Since the construction of the "Old Dock" others had been built from time to time as trade required, the site chosen for them being the river foreshore in front of the town of Liverpool. In the second quarter of this century, especially, many new docks were constructed by Mr. Jesse Hartley, dock engineer, to whose ability and practical knowledge Liverpool undoubtedly owed much of its commercial greatness. From 1845, also, Birkenhead, on the Cheshire or left bank of the Mersey, entered into competition with Liverpool. Docks on a very large scale had been laid out there, and already partly constructed, when, in 1858, the Mersey Docks and Harbour Board was incorporated by Act of Parliament to take over and manage as one concern the whole of the

HORIZONTAL ENGINE.

CONSTRUCTED BY MR. ALFRED DODMAN, ENGINEER, KING'S LYNN.

Liverpool and Birkenhead Docks, which, since the date named, had formed one estate. In 1871, although the Birkenhead Dock system had been for some time completed according to the Parliamentary plans, the Dock Board was urged to consider the desirability of commencing, without delay, further dock extensions on the Liverpool side of the river, on such a scale as would meet the pressing wants of trade, and provide for the growing requirements of shipping, which was everywhere advancing in size and tonnage. The result of this pressure was an exhaustive inquiry into the question by a Committee of the Board, with the outcome that the author was directed to consider and report as to the alterations and additions which might be requisite to meet the probable requirements of the great and increasing commerce of the port. Reports and plans were duly submitted by the author, showing schemes of dock extension both at the north and the south ends of the Board's Liverpool estate; and in the session of 1873 Parliamentary powers were obtained for the construction of new dock works, estimated to cost on the whole £4,100,000. The works referred to were designed to meet the wants of the port for some time in advance from the date of the Act. It was, therefore, provided that the expenditure was not to exceed £500,000 per annum, and, accordingly, the works had been spread over many years. The effect had been that, before any of the several new docks were opened, trade in its natural advance had been ready to fill them. The general design of the New North Docks comprised the enlargement of the Canada Basin, and the improvement of its entrance, so as to make it available for vessels of the largest class, and the construction of the following new docks:—The Langton Dock of 18 acres, serving as a half-tide dock, the Alexandra Dock and branches, 44 acres, and the Hornby Dock, 17 acres. The Canada basin and Langton entrances had been designed to give as direct a lead from the river as possible, so that vessels could pass quickly through, allowing of a large number docking on one tide. They had been found to work excellently; large steamers of 34,197 tons aggregate burden had been docked and undocked in one tide of two and one-third hours. A most important point in connection with the Canada Basin and approaches was that of depth. After careful consideration, it was decided to lay the sills of the entrances at the level of 12ft. below Old Dock Sill, or 2ft. below low-water of equinoctial spring-tides, and the floor of the basin and approaches at a level 2ft. lower. In order to ensure the maintenance of the required depth without dredging, special means had to be adopted to clear away the silt deposited every tide; and to this end sluicing-culverts had been constructed in all the walls of the basin, the flow of water from which cleared silt away for a considerable distance in front of the walls. To effect the removal of silt deposited beyond the range of the wall-sluices, sluice-pipes had also been laid under the floor of the basin; and these were fitted at short intervals with vertical branches having outlets through the floor of the basin. The outlets were closed by framed discs of greenheart, which effected the distribution of the sluicing water over the area to be cleared. The fairway to the basin was also maintained clear by sluices laid in the foundations of the north and south jetties, which, besides serving for this purpose, limited the area within which deep water had to be maintained, and acted as guides against which vessels entering or leaving the basin might bear. The Langton Dock had an area of 18 acres, and served as a vestibule for shipping, while its north and west quays were provided with sheds suitable for the discharge of vessels of the largest class. The graving docks, situate on the east side of the Langton Dock, were each 950ft. in length, but had intermediate gates in the centre, so that the inner chambers could be used as "long time," while the outer were used as "short time" docks. The graving docks were built entirely of concrete. A 30-ton hydraulic crane furnished means of handling screws, rudders, &c., and was so arranged as to be capable of being used at any of the four graving-dock chambers. At the entrance to the graving docks was an engine-house, which was the centre of power for the district; it contained hydraulic main engines, of 350 h.p., besides powerful engines and pumps for draining the graving docks of such water as could not be run off with the tide. On the south quay of the Langton Branch Dock was a hydraulic crane of 100 tons power, of a novel character, the lift being made by a direct-acting inverted hydraulic cylinder, a mode of working which permitted of nice adjustment of the loads. The Alexandra Dock, designed to accommodate the largest steamers, had a length of 1,600ft., and its quays were all provided with substantial sheds 95ft. wide in one span. The Hornby Dock was partly used as a timber dock, and partly for ordinary trade; for the latter purpose a shed 125ft. wide was now in course of erection on its south quay. The principal points of these northern docks were illuminated at night by electric lights, placed on masts 90ft. high. The total estimated cost of the whole of the works was £2,727,000, and, since their completion, they had accommodated sea-going ships of the largest class, with an aggregate of 18,000,000 tons. The new southern extension comprised a chain of docks from the Herculaneum, which had been constructed by the author in 1868, to the old Brunswick Dock. These new docks had been named the Harrington, Toxteth, and Union, the latter forming the link between the new system and the old. At the same time, the Herculaneum had been greatly enlarged, and, on its eastern and southern quays, special accommodation for petroleum had been provided by the excavation of casemates in the solid rock. The Harrington and Toxteth Docks were laid out for general trade, and were provided with first-class sheds, those on the western quays being single-storey sheds, 150ft. wide, whilst on the east side double-storey sheds of novel character had been erected, the width of these sheds being 95ft. The discharge of goods on to the floors of the latter sheds was effected by a number of hydraulic cranes mounted on the roof, and capable of dealing with any load up to 30cwt. Through the Union Dock, vessels which could not on neap-tides, by reason of their deep draught, get into the river over the Pluckington Bank and shallow sills of the older docks, were enabled to dock and undock through the chain of new docks into the river by the Herculaneum entrances, now deepened to 12ft. below Old Dock Sill. The level of the water in the older docks referred to would be maintained, when necessary, by impounding and pumping. The bulk of the excavation from these docks was a soft sandstone rock, and, no place of deposit being obtainable, it became necessary to send the rubbish to sea, which was done in steam hopper barges of 500 tons capacity. The estimated cost of the New South Docks was £1,372,000. By the north and south extensions, forming the subject of the paper, the area of the Liverpool Docks had been increased from 252 acres, the area at the time of the passing of the Act of 1873, to 363 acres, the present area, and the quayage from 18 miles to 24 miles.

A NEW FORM OF SIEMENS FURNACE.*

It would be necessary to write a complete history of the regenerative gas furnace to give any idea of the diversity and difficulty of the problems which Sir William and Mr. Frederick Siemens had to solve before their furnace, now so well known to iron and steel manufacturers, was made available for use in metallurgical operations. Amongst these problems may be instanced the preliminary heating of the gas as well as of the air, so as to introduce both of them into the heating chamber at a high temperature, the form necessary to be given to the regenerators in order that the heat should be deposited and recuperated in a methodical and rational manner, the arrangements for reversing the direction of the flame and for effecting a uniform diffusion of its heat throughout the heating chamber, all of which, simple as they now appear, involved a large amount of careful consideration on the part of the Messrs. Siemens. Besides these main features that had to be discovered and applied, we are also indebted to them for all the details that constitute the indispensable accessories used in the construction and working of the regenerative gas furnace. By their work the employment of reactions and metal-

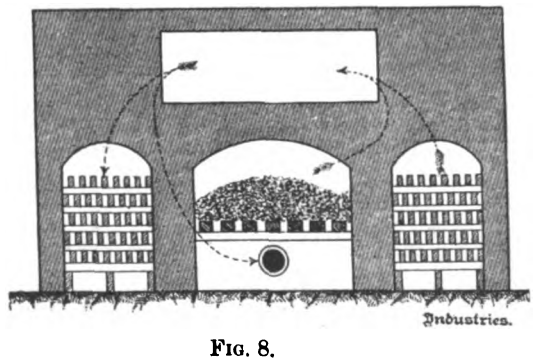

Fig. 8.

urgical operations, foreshadowed by chemical research, have been rendered possible and practicable, which, but for their furnace, could have had no practical application, and would therefore have been unavailable to manufacturers.

The great economical idea embodied and carried out in the regenerative gas furnace is perhaps best illustrated by comparison with such a meritorious invention as Neilson's hot blast stove. In this case the temperature of the blast was raised by means of fuel separately burned for that purpose, but in the case of the Siemens regenerative gas furnace the heat below the temperature of the work carried on in the furnace is impounded in the regenerators, and applied to heat up the gas and air supporting combustion. In high temperature furnaces the heat below the temperature of the work to be performed therein is by far the largest proportion of the total heat produced, and previously to the introduction of the Siemens furnace this heat had been lost by being allowed to pass away with the waste gases to the chimney. This circumstance was clearly explained by Lord Armstrong at the meeting of the British Association at Birmingham in 1865. By heating the inflowing gas and air the temperature of the flame in a furnace may be raised to almost any extent; in fact, the heat attainable under these conditions is only limited by the power of resistance of the materials of which the furnace is built, and thus the highest temperatures required in metallurgical operations are obtained with facility by the expenditure of a moderate amount of fuel, especially since the introduction by Mr. Frederick Siemens of the method of heating by radiation, by which means the durability of the furnace has also been much increased. In considering the details of construction of this ingenious apparatus it occurred to Mr. E. Biedermann and Mr. E. W. Harvey, who are on Mr. Frederick Siemens' technical staff, that possibly further economy in fuel might be realised by a re-arrangement of some of the parts of the regenerative gas furnace. Their attention was directed to the conversion of solid fuel into the gas in the producer and to the relatively high temperature at which the products of combustion passed from the furnace into the regenerators, as also to the chemical composition of these products, which temperature and gases they thought might be utilised in the gas producer. As is well known the production of carbonic oxide in the ordinary gas producer is the result of the decomposition of the carbonic acid formed in the first instance above the grate by incandescent carbon in the upper portion of the producer, according to the equation $CO_2 + C = 2CO$. Carbonic acid at a high temperature is produced with the development of heat in the lower layers of the fuel, which is transformed with the absorption of heat into carbonic oxide in traversing the red-hot fuel above, whilst hydrocarbons are distilled from the coal used, and leave the producer with the carbonic oxide produced. In the new form of Siemens furnace the gaseous products of combustion from its heating chamber are delivered under the grate of the producer. These gases consist of carbonic acid, water in the gaseous state, and nitrogen, all in an intensely hot condition. The production of carbonic acid may therefore be dispensed with (as a portion of the hot gaseous products of combustion are already in that state), provided the heat usually developed in its production and necessary for its conversion into carbonic oxide is compensated for by the heat brought in by the products of combustion. A producer so arranged will become a converter, in which the gaseous products of combustion will be reconverted into combustible gases without any diminution of the temperature of the solid fuel. Although such a result may appear at first sight paradoxical and unlikely, it has been proved by experience in the working of several furnaces during the past nine months, and may be explained by the presence in the burnt gases of a proportion of nitrogen large enough to carry the heat necessary for the reaction.

It is possible by a very simple reasoning to explain the cause and source of the economy realised in a new furnace. If oxygen be admitted below the grate of a gas producer filled with incan-

Digitized by Google

descent coke (Fig. 6), carbonic acid will be formed in the lower zone and produce a certain quantity of heat. This carbonic acid will be decomposed in the upper zone, and absorb a portion of this heat. From this reaction it is seen that the weight of carbon gasified in the lower zone is equal to that of the carbon gasified in the upper zone, and if we suppress the production of carbonic acid and replace it by superheated carbonic acid from an external source of supply, half the fuel should be saved.

The furnace about to be described is provided with air regenerators only, but must be distinguished from furnaces in which the air alone is heated. Such furnaces are necessarily wasteful, as only a portion of the heat contained in the burnt gases can be theoretically recovered, and such a result is not attainable in practice. In the new furnace on the contrary the gases leaving the furnace are partly directed below the grate of the converter producer, and partly into an air regenerator, so that the whole of the heat is utilised as in the original Siemens furnace, but in a different manner. The air regenerators perform the same functions as formerly; but the heat which in the old furnaces was deposited in the gas regenerator is now utilised to bring about the conversion of the products of combustion into combustible gases, to distil the volatile material in the coal, and to raise these volatile constituents to a certain temperature before their arrival in the furnace chamber. The economy of the new Siemens furnace over the original form may rise as high as 50 per cent. when coke is the fuel employed. When coal is used the economy will be considerably increased, because the sensible heat of the gases necessarily lost in the original Siemens furnace is saved in this form, and the formation of tar and soot in the flues is avoided.

Figs. 7 and 8 show the relation which exists between the ordinary and the new type of Siemens furnace. In the first case the waste gases are directed through two regenerators, while in the second case the waste gases are partly directed through an air regenerator, and partly through a converter producer. In both cases the waste heat from the furnace is entirely utilised, leaving only heat sufficient for chimney draught; but as in the new furnace a portion only of the products of combustion passes away by the chimney, whilst the remainder returns to the furnace after passing through the converter producer, the heat necessary for producing draught in the chimney is diminished to the same extent. This represents a further saving in fuel. As there is no gas regenerator in the new furnace there is no loss of heat by radiation from it, and further economy is thereby also effected. In both furnaces there is reversal of the currents of air and gas so as to produce uniform diffusion of heat through the furnace chamber; in both, too, the air and gas are delivered into the furnace at a very high temperature.

This furnace may be constructed in various forms, the one shown in Figs. 1–5 having been used with success for heating and welding iron. It is a radiation furnace, heated by means of a horseshoe flame; this form of flame offers advantages in this as in ordinary regenerative gas furnaces, but its adoption is not obligatory, as the flame may be made to traverse the heating chamber from end to end in the usual manner. The same letters indicate the same parts in all the figures. AA^1 are reversible regenerators for air, on the top of which is built the gas producer or converter B, of which FF^1 are the charging hoppers and NN^1 the grates. The heating chamber E adjoins the producer and rests on the ground, or in some cases a pit may be provided below it. CC^1 are the flues leading the combustible gas to the furnace chamber E, the passage of the gas in these flues being controlled by the valves DD^1 at the two ends of a rocking-beam, so that the outlets are opened and shut alternately to convey the gas to one or other of the ports GG^1 of the heating chamber E. HH^1 are the air ports of the heating chamber, communicating through the flues KK^1 with the regenerators AA^1. II^1 are steam jets placed in the return flues for directing a portion of the waste products of combustion to the grates of the converter. J is the valve for reversing the direction of the air flowing into the furnace, and of the products of combustion through the regenerators to the chimney flue. OO^1 are hinged caps for alternately admitting and shutting off the products of combustion from the heating chamber to the converter. These caps are worked automatically by means of connections attached to the rocking beam, the same movement which closes D opening O^1, and that which closes D^1 opening O. Qq are doors for giving access to the grates of the converter for clearing them.

The *modus operandi* of the furnace is as follows:—Gas from the converter B passes through the flue C^1 and the valve D^1 to the gas-port G^1, and into the combustion chamber h^1 g^1. Air for combustion passes through the regenerator A^1, the air-flue K^1, and the air-port H^1 into the combustion-chamber, where it meets the gas from the converter, and combustion ensues. The horseshoe flame sweeps round the heating-chamber E, the products of combustion passing away by the second combustion-chamber h g, and going partly through the regenerator A and reversing valve J into the chimney-flue and partly down the flue G, whence they are drawn by means of the steam jet I through the capped inlet under the grates NN^1 of the producer B, there to be converted into combustible gases. From time to time the direction of the flame in the furnace is reversed by manipulating the rocking beam, carrying the valves DD^1 and the reversing valve J in the usual manner of working regenerative gas furnaces. An auxiliary steam jet is provided for the purpose of supplying atmospheric air to start the producer when the furnace is first heated up.

The new form of regenerative gas furnace has been applied in this country to the heating and welding of iron, to which uses its application is being extended in England and abroad, whilst furnaces are in course of construction to apply it for puddling iron and for copper and steel melting. Altogether, ten furnaces for these purposes are in course of construction, in addition to ten furnaces already at work for heating iron. The first furnace of this kind was constructed at the Pather Iron and Steel Company's works at Wishaw for welding iron, and much credit is due to the proprietors for having had the enterprise and public spirit to make the first application of this improved regenerative gas furnace. The working has been eminently satisfactory from the commencement. The success of the first application of the furnace proves the correctness of the principle upon which it is constructed and the means adopted for carrying it out. The results of working during the past nine months have shown an average saving of 5 per cent. in waste on the weight of the iron heated, and a saving of upwards of two-thirds of the weight of coal used, and a greater money saving, owing to the inferior quality of the fuel employed as compared with that used in their other furnaces fired with solid fuel. From the total saving thus realised should, however, be deducted the cost of raising steam, for which purpose the waste heat of the old furnaces is utilised. Allowing for separate boilers, the saving effected by the use of the new system in a furnace heating eight tons of iron per shift is nearly eighteen tons of coal per week, and the money saving in iron and coal exceeds £1,000 per annum

This new furnace has also been recently applied for heating billets by the United Horse Shoe Company of London, and in this case the results are quite as satisfactory or even better than those just given, as is shown by the accompanying table:—

	Date.	Number of Charges per Shift.	Duration of each Shift.	Weight of Billets Heated (30in. by 2½in. by 2¼ft.)	Average Time required for Heating to Welding.	
	1889.		a.m. p.m.	Minutes.	Tons. Cwts.	
a	Sept. 13	11	5·45 to 5·25	21	8 16	a
b	Sept. 14	6	6·0 to 12·15	20	4 16	b
c	Sept. 16	11	5·45 to 5·30	21	8 16	c
d	Sept. 17	11	5·45 to 5·30	26	8 16	d

Continued below.

	COAL.		
	Weight Used.	Used per Ton of Billets.	Quality.
	Cwts.	Cwts.	
a	17½	1·9	Newcastle small.
b	8	1·7	Newcastle cobbles.
c	17¾	2·01	½ Newcastle small. ½ London screenings.
d	18¼	2·08	London screenings.

It will be noticed from these results that in this furnace eleven charges are made in less than twelve hours, each weighing about 16cwt., and yielding in the finished state as horseshoe iron 15cwt. per charge, or 8·25 tons in the day. The amount of small coal used was about 18cwt. per shift. This is equivalent to 2cwt. per ton of iron heated, which, it will be admitted, is a most satisfactory result; in one case the consumption of coal was even reduced to 1·7 cwt. per ton, each billet coming out at a full welding heat and rolling into a sound bar. The coal used each day is indicated in the table.

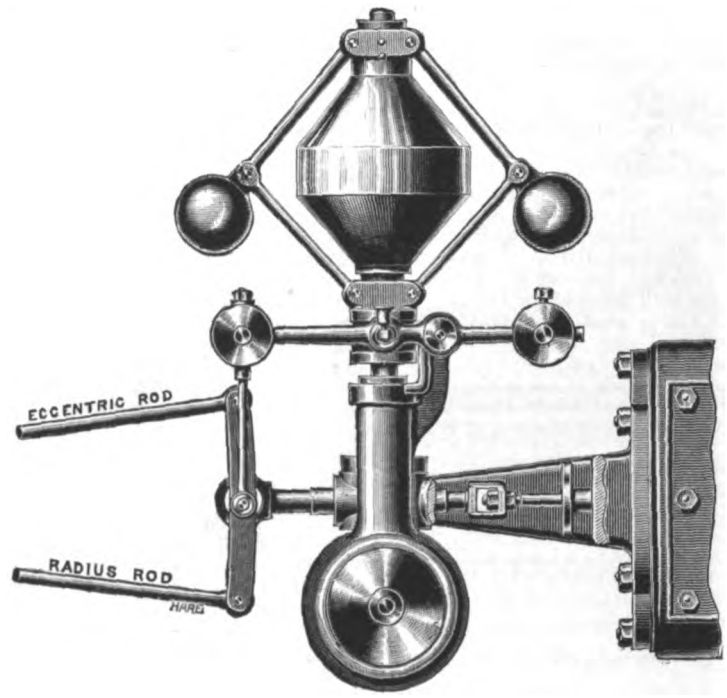
The following are analyses of gas made in the converters at Pather and in London respectively:—

Pather Co. *From Wishaw Coal (nuts).*		United Horse Shoe Co. *Newcastle Cobbles.*	
CO_2	4·6	CO_2	4·5
O	nil	O	nil
CO	23·0	CO	22·5
H total	17·4	H	16·3
C vapour	1·5	CH_4	2·6
N	53·5	N	54·1
	100·0		100·0

From these analyses it will be seen that the proportion of CO_2 in the gas made in the converters is not greater than that made in the ordinary Siemens producer.

Besides the advantages in the saving of fuel and metal, it is desirable to call attention to the simplicity of design of the new furnace, owing to which its cost of construction is not much greater than that of a solid-fuel furnace, while its cost of maintenance is very much less. Its cost of construction is found to be about two-fifths of that of the old form of regenerative gas furnace, of the same productive capacity, with separate gas producers and gas regenerators, and the space occupied below ground is also considerably reduced. A saving of labour attends the employment of the new furnace, as, owing to the producer being connected with the furnace, the same men can attend to both, and the labour of firing is reduced in proportion to the reduced consumption of fuel.

In conclusion, the following advantages may be claimed for the new furnace as compared with solid-fuel furnaces used for heating and welding iron, viz.:—(1) A saving in fuel, amounting to, say, two-thirds in weight, and after allowing for raising steam in separate boilers, this saving is fully equal to 5cwt. of coal per ton of iron heated; (2) a reduction in the waste of iron equal to 5 per cent. upon the weight of metal heated; (3) a saving in labour and repairs which will probably compensate for the extra cost of the new furnace.



Taking a furnace to heat 10 tons of iron per shift, or 110 tons per week, the following calculation gives the money saving realised by the adoption of the new furnace:—

110 tons iron at 5cwt. per ton = 27½ coals saved at 6s...	£8 5 0
110 ,, ,, at 5per cent. = 5½ tons iron at £4	22 0 0
Being.....	£30 5 0

per week, or say, £1,500 per annum.

IMPROVED EXPANSION GEAR.

Constructed by Messrs. Ransome, Sims, & Jefferies, Engineers, Ipswich.

We illustrate herewith a new form of expansion gear for steam engines which has recently been brought out by Messrs. Ransome, Sims, & Jefferies, engineers, Ipswich. An independent gridiron expansion valve works upon the back of the slide valve, and is operated through a knuckle-joint by a link, one of whose ends is actuated by the cut-off eccentric and whose other end is pivoted to a radius rod. The travel of the valve is governed by the position of the link in relation to the knuckle-joint, and this position is varied according to the load on the engine by a sensitive governor to which the link is connected. The cut-off can by this mechanism be varied between wide limits of the stroke.

THE CHANNEL TUNNEL.

At the annual meeting of the Channel Tunnel Company it was agreed to deposit a Bill in Parliament asking for powers to construct the tunnel, and we understand that the Government has intimated its intentions of opposing it, so that its chances of passing are small. Sir E. Watkin, at the meeting, said he had no jealousy about the proposed bridge across the Channel, as he did not think it would interfere with the better means of communication offered by the tunnel, although he doubted whether the Great Powers of the North of Europe would permit the erection of piers and the obstruction of a bridge in the Channel, which was already dangerous enough. They could make the tunnel for one-tenth part of what the bridge would cost, and clearly it would be the least obstructive to navigation. At the same time, he had a perfect belief that there would be work enough both for the tunnel and the bridge, if the promoters of the latter could find the thirty-four millions necessary to make it.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 81.)

PARIS, 21st January, 1890.

IRON.—The recent great rise in the prices of iron has visibly checked the current of business in the markets of the capital, where it has not been brisk for some months past. It is to be feared that building operations will be restricted to what is strictly necessary. With this prospect there is some doubt whether the high rate of £8 16s. for bars and joists can be long maintained. The situation is better in the provinces, where buyers are less reluctant to enter into fresh engagements. But even there founders are complaining of the check to business given by the recent rapid advance in prices. Production is in some districts retarded by the want of coal, and the cost has been considerably augmented by the high prices of the latter.

FRENCH EXHIBITIONS ABROAD.—An important meeting of Parisian manufacturers and merchants was held last week at the Hôtel Continental, for the purpose of nominating a committee to carry out the work of organising annual exhibitions of French manufactured goods abroad. The chair was taken by M. Watbled, Consul-General of France, who was supported by M. Pingot, French Consul at St. Petersburg, and M. Gründwald, Delegate Commissioner of the Russian Section at the Paris Exhibition. These gentlemen showed the necessity of giving a stimulus to French trade abroad. "It cannot be permitted," said they, "that Germany and England should carry on a trade with Russia to the value of 150,000,000 roubles annually, while the value of the commercial operations transacted with France scarcely reaches 12,000,000."

BERLIN, 20th January, 1890.

SILESIAN IRON IN 1889.—The record of the Upper Silesian iron industry in 1889 is in all points satisfactory in the highest degree. In that year we find, now that its history is being written, exceptionally important progress, both in the development of the industry and in the extension of the trade of that district. The total production of pig iron amounted to 480,147 tons against 421,939 tons in 1888, an increase of 10·6 per cent. This quantity was made up of the different classes in the following proportions, the figures in parentheses being the proportions in 1888: Spiegel and forge pig, 70·46 (71·8); Bessemer, 4·87 (6·4); Thomas, 19·17 (17·1); foundry, 5·49 (4·3). The proportion of Thomas iron steadily increases year by year. For complete statistics of the production of finished iron and steel we shall have to wait some weeks yet, but it is known that the business of the last quarter will compare very favourably with that of the corresponding period of 1888. In the first three quarters the make of half-wrought amounted to 9,456 tons, and that of finished to 240,880 tons, against 7,675 tons and 240,762 tons respectively in the previous year. In prices the rise in the second half-year was, for bars, from 150s. to 180s.; for boiler plates, from 195s. to 240s.; and for steel rails, from 130s. to 155s. a ton. In foundries and machine shops the year was a period of great activity.

THE PHOTOGRAPHIC EXHIBITION.—The International Photographic Exhibition at Breslau, which was formally opened on the 15th inst., is a very comprehensive and well-arranged undertaking. The leading idea is to show the progress of the art in the last fifty years. But the exhibits of recent work have an interest of their own, both as specimens of what may now be accomplished by means of the camera, and as a record of some recent important events. Güssfeld and Saltzmann show some fine photographs taken by command of the German Emperor on the occasion of his visits to Norway, Greece, and Turkey.

CORN MARKET AT MAGDEBURG.—A number of Magdeburg merchants and others interested in the corn trade have resolved to establish a corn market in that town. The market days will be Wednesdays and Saturdays.

THE INTERNATIONAL GARDENING EXHIBITION.—The preparations of the Great International Gardening Exhibition, to be held here from April 25th to May 5th next, are in a forward state. Applications for space may be made up to March 1st. This Exhibition, which is wide in its scope, will be one of considerable importance.

CELLULOID MANUFACTURE.—The firm of May & Co., celluloid manufacturers at Plagwitz and Eilenburg, has been turned into a share company, with a capital of one million marks. This company, which proposes to greatly extend the manufacture, will be known as the "Deutsche Celluloid-Fabrik."

CONSUMPTION OF SUGAR.—Official statistics for the years 1889, 1888, and 1887, just published, show the consumption of sugar in Germany to average 17·2lb. per head of the population per year during that period.

ELECTRICITY.—Dr. Werner Siemens has left the firm of electricians known by his name, and is intending to devote himself to scientific pursuits. The same course is being followed by his chief engineer, M. von Hefner-Alteneck.—It is intended to connect Berlin with Vienna by telephone. Lines already exist between Berlin, Dresden, and Breslau, and also between Vienna, Brünn, and Prague, so that the completion of the connection will not be a very costly matter.—The Allgemeine Electricitäts Gesellschaft has acquired the rights of the Sprague patents and of the Popp compressed air system for the whole of Germany.

VIENNA, 20th January, 1890.

BOURSE.—During the last week or so industrial securities have experienced great fluctuations. The shares of the Alpine-Montan Company decreased 2fl., those of the Prague Iron Industry Company 7fl., and the Rima Murany Works shares decreased by 2·50fl. Other shares increased, but prices were equalised shortly afterwards. The tendency is quiet at present.

COALS.—The situation does not change. An extraordinarily brisk demand is to be noted in the coke market. Russia is the best buyer, and is wanting coke for the working up of the large quantity of rails for the strategic railways. One hundred and eighteen thousand tons of rails and 11,000 tons of other materials are shortly to be delivered for this purpose.

IRON.—There is a sensible improvement in all branches of the iron industry as compared with the same period of many previous years. The brisk demand for pig iron is causing large imports, as the home works are not yet able to cope with the orders. Machine manufactories do not guarantee the term of delivery. The production of iron in the last six years is as follows:—

	Tons = 1000kg.					
	1884.	1885.	1886.	1887.	1888.	1889.
Pig iron	892,000	803,000	814,000	794,000	894,000	980,000
Finished iron...	720,000	640,000	640,000	630,000	710,000	780,000

The Austrian manufactory of arms was too small for the execution of all demands, and now the Hungarian branch already has plenty of orders on hand. The first thousand rifles are to be delivered by the Hungarian factory in June next. The Alpine-Montan Company is entering into a contract for twenty-five years with seven small works in the neighbourhood, for the purpose of using up the pig iron and of dividing the finished material in the proportion of 86 for the Alpine-Montan Company and 14 parts for the other works.

ELECTRIC LIGHTING.—On the 14th inst. the new installation at the Vienna Rathhaus was successfully opened. The general effect was excellent, and the authorities expressed themselves as highly gratified. The various parts of the building—banqueting hall, council chamber, galleries, and passages—are all liberally supplied with the new light. Altogether there are 955 glow lamps for the interior, and 160 glow lamps and 17 arc lamps for the outside.

BRUSSELS, 21st January, 1890.

THE COAL MARKET.—On account of further differences between masters and men the strike has opened out afresh in the Charleroi district. Coal is very scarce, of course, and it is totally impossible to settle any price. Coal and coke are arriving in considerable quantities from England and Germany. Scotch, South Wales, and Tyneside coal are all quoted at less figures than native coal, and the sellers are still able to obtain a large profit. With these supplies it is possible to carry on the industries of the country, but every reasonable being is sorry that the present state of things necessitates the introduction of a foreign article. Until the strike has ceased it is impossible to quote any prices or arrange any contracts.

THE IRON MARKET.—The situation of the iron trade becomes more difficult every day. A short time ago it was hoped that affairs would settle down on the resumption of work by the miners, but the new trouble has made the state of the market worse than ever. In fact the forgemasters and iron manufacturers have simply had to pass under the Caudine Forks of the foreign coal owner. The Association of Forgemasters at Charleroi have proposed that a council of four lawyers of repute shall be appointed to consider the possibility of a settlement of the present state of things, and whether anything can be done to force the completion of coal orders. The Congo Railway Company has ordered 1,500 tons of steel rails from Belgian steel works. The Société Cockerill has been able to beat Krupp in the securing of contracts for the supply of rails to Denmark.

DÜSSELDORF, 21st January, 1890.

COAL.—The dearth of coal is more and more keenly felt in all the manufacturing industries, the demand on the part of Belgian consumers, created by the colliers' strike, having seriously aggravated the difficulties of the situation. Though the market is, of course, very firm, no attempt is made to unduly force up prices. The following is the latest list issued by the Dortmund "Coal Club":—Gas coal, 14s. 6d. to 16s.; coking coal ("roughs"), 12s. to 13s., (large) 14s. to 16s., (washed nuts) 14s. to 16s.; dry burning ("roughs"), 11s. to 12s., (large) 16s. to 19s.; nuts, 17s. to 20s.; small, 10s. to 11s.; "smudge," 7s. to 8s.; blast-furnace coke, 26s. to 27s.; foundry coke, 27s. to 28s. 6d.; briquettes, 14s. to 16s. a ton.

IRON.—The efforts which are being made to increase the output of iron ore are beginning to tell on the production, and there are good grounds for believing that the supply in 1890 will be amply sufficient to satisfy the demand. In this fact we have one guarantee for the stability of the iron market. The supply of coal gives rise to some anxiety, but in other respects there is no reason for misgiving concerning the trade of 1890. At the present time the market is animated, and, as prices have steadied themselves, buyers regard the future with more confidence. Most of them have bought far forward, and as the manufacturers have in consequence plenty of work in hand, the market is not sensitive to small influences. Deliveries of foreign pig bought in the excited times of November are now being made in large quantities.

CYCLE EXHIBITION.—The second great exhibition of bicycles and tricycles, and "apparatus appertaining thereto," will be held in the Crystal Palace of Leipsic from February 22nd to March 12th, 1890. Much interest is manifested in this exhibition, not only by native manufacturers, but by their foreign rivals. The latter will be represented by the principal cycle-making firms of England, Austria, Holland, and Belgium.

LILLE, 21st January, 1890.

TEXTILE MANUFACTURES.—Business in linen goods is more active, the turnover at Armentières being from 10 to 12 per cent. greater than it was a week ago. But a comparison with the corresponding periods of the last three years is unfavourable to 1890. This is no doubt due in part to the fact that many commercial travellers and buyers' agents are laid up with influenza. At Roubaix, probably from the same cause, the market for woollen goods is less animated. Business in raw wool is for the moment somewhat slack, Australian being less inquired after, and prices a little weak. The proposal to tax foreign wool is being angrily opposed as inimical to the interests of French industry.

FLAX AND YARNS. The flax market is now active, Walloon, Douai, and De Bergères goods being largely dealt in. There is, however, a tendency to weakness in prices. The market is quiet for Russian flax. Buyers are unwilling to pay the high rates now prevailing. Italian hemp is becoming firmer in price. Business in tows is limited to the needs of the moment. Imported goods are a little dearer. There is not much doing in yarns, the market being thinly attended, a circumstance due chiefly to the influenza epidemic.

A SHUTTLELESS LOOM.—We have this week seen in action the shuttleless loom which seems destined to revolutionise the system of weaving. It is on view by ticket at No. 44, Rue Deregnaucourt, at Roubaix. It works easily, and produces fabrics of all kinds and in all materials in the most perfect manner and with great speed. The rate of production is a quarter of a yard a minute; this, with a width of 9ft., which it is capable of giving, is three-quarters of a square yard a minute, or 45 square yards an hour, for ordinary light goods. It is needless to say that this machine is exciting great interest in this district, its apparent capabilities being immense.

AMSTERDAM, 20th January, 1890.

THE CANAL BETWEEN GHENT AND TERNEUZEN.—This canal is going to be closed for forty-two days, from April 1st next, owing to repairing works at the great locks of Terneuzen.

RAILWAYS.—There is a dispute between the State and Dutch Railway Company concerning the proportion of expenses to be borne by each in the construction of the terminus for the railway from Maassluis to the Hoek von-Holland. The parties have agreed to submit their differences to arbitration.

DUTCH ENGINEERS FOR CHILI.—Consequent upon the recent visit by a Chilian State Commission to Holland in order to inspect the great works of hydraulic engineering, the Government of Chili has engaged two Dutch engineers, to whom important works are going to be entrusted. It has also appointed a Dutch gentleman, Mr. J. Kraus, to be a professor in hydraulic engineering at the University of Santiago.

TELEPHONES AT AMSTERDAM.—The Dutch Bell Telephone Company has decided to lay underground cables, if the necessary permission can be obtained.

NEW INDUSTRIAL COMPANIES.—Among the new industrial companies brought out recently in Holland, there are a Dutch boot and shoe factory, with a capital of £50,000, and an association of capitalists to carry on marble quarries in Spain. This venture, called "La Hollandesa," has a capital of £41,000.

SUGAR.—Most of the Dutch beetroot sugar manufactories are closing now, as the manufacturing time of about a hundred days has passed. Some of them, however, will be active until the end of February. When the Colonial Budget for 1890 was discussed in the Second Chamber of the Parliament, several members proposed new taxes on the cane-sugar industry. Mr. N. P. van der Berg, ex-president of the Java Bank, has given a warning against this proposal by giving a very interesting calculation of the cost of production of the Java cane sugar. There are 14 provinces in Java with 104 manufactories, of which the crop in 1888 was 3,922,630 piculs (one picul = 135·87lb.). The mean manufacturing price over 1888 was 11s. against 11s. 1d., 12s. 5½d., and 13s. 5d. in the years 1887, 1886, and 1885. A manufactory for treating 50,000 piculs wants a capital of about £50,000. The real figure ought to be taken as being 12s. 6d. per picul of Java cane sugar.

SLUICES OF YMUIDEN.—The Minister of Public Works has decided to give a depth of 10 metres (32ft. 10in.) to the sill of the new Ymuiden sluices. As in the meantime the new canal from Amsterdam to the Rhine will be ready, it is evident that an increase of the tonnage in the trade of Amsterdam is to be expected.

Digitized by Google

PETROLEUM.—The three places in Holland where this oil is principally imported are Amsterdam, Rotterdam, and Flushing. In the first two places tanks have been erected, and Flushing will soon have a tank of 13,000 barrels. During 1889 there were imported in Rotterdam and Flushing about 673,963 barrels, against 467,936 barrels in the year 1888. In Amsterdam about 245,000 barrels of petroleum were imported in 1889, against 263,000 barrels in 1888. This decrease may be ascribed to the need of tanks in the beginning of the year 1889.

STRIKE AT GRONINGEN.—The large flax spinning mill of Mr. Dumonceau, at Groningen, has had to be closed owing to the strike of the hands. It is stated that the owner has paid away nearly £15,000 in wages in the last six years, whilst the capital invested only yielded an average interest of 3½ per cent.

THE LABOUR QUESTION.—The First Chamber of the States-General has passed the Government Bill to prolong to 1892 the State inquiry by a Royal Commission into the economic condition of the working classes.

ACCIDENTS IN FACTORIES.—In connection with the exhibition of appliances to prevent accidents to workmen in factories, which exhibition will shortly open in Amsterdam, it is proposed to found a national society having the same object in view. A great deal of public interest has been shown in this project, which is to be ventilated at a public meeting called for the end of this month. It is felt that in a country like Holland, where the legal liability of employers for compensation in the case of accidents to their artisans does not exist, and has no chance of being adopted, the employers themselves, recognising that they owe their workpeople a little more than bare wages, ought to combine at least to lessen the dangers to life and limb which exist in every factory more or less. It is proposed to found a society of employers upon the mutual plan, with a committee of experts, which would visit the factories of the members from time to time, reporting defects whereby dangers to life and limb are increased, and suggesting remedies. The society will also organise lectures and issue pamphlets, give rewards for useful inventions tending to minimise danger, award medals to employers who have the safest factories, and finally hold exhibitions of appliances with the same purpose.

THE SOUTH AFRICAN MAILS.—These mails will now leave Flushing for Cape Town, Natal, Port Elizabeth, the Delagoa Bay, &c., every fourteen days, but letters will not be forwarded by this route unless bearing the inscription "*viâ* Castle Line." The postage will be 5d. in the case of letters of ½oz., and 1d. for printed matter (1½oz. or under).

THE SUGAR TRADE IN EAST INDIA.—The First Chamber of the States-General has sanctioned the Government Bill which authorises the Governor-General to admit, temporarily, foreign vessels to the coasting trade to transport sugar in the season. Up to the present Dutch vessels only were allowed to engage in a coasting trade.

COPENHAGEN, 18TH JANUARY, 1890.

NORWEGIAN RAILWAYS.—The railways in Norway have an aggregate length of 1,562 kilometres, of which 1,494 kilometres are State railways, and the remainder, the Christiania-Eidsvold Railway, 68 kilometres. While in Sweden new railways are constantly being built, both State railways and private lines, this is not the case in Norway, though several new and important railway schemes are under contemplation. The general improvement in trade and industry has benefited the Norwegian railways during the past year, the takings for the first ten months amounting to 7,363,000kr., as against 6,616,000kr. for the corresponding period during 1888, or an improvement of about 11 per cent. The improvement is extended to the different lines, with exception of the Drammen-Skien line, where a slight reduction is noted. Rather more than two-thirds of last year's increase in takings come from the goods traffic, and consequently somewhat less than one-third from the passenger traffic. For the main line the working year 1888-89 gave a surplus of 884,000kr., so that the shareholders' dividend was raised 1 per cent., to 7½ and 6½ per cent. respectively for preference and ordinary shares. About 200,000kr. were expended in locomotives and carriages. The north line (Eidsvold-Drontheim), which, from a financial point of view, consists of various sections, also shows some improvement, the transport of sulphur ore having given considerable income; of its five sections, two, however, give no dividend to the shareholders, and the other three respectively 2·5 per cent., 1·8 per cent., and 0·8 per cent. The Meraker railway shows a considerable increase in income (about 14 per cent. as compared with 1888), but still only 2 per cent. dividend was available to the shareholders. The Kongsvinger railway has paid a dividend of 2½ per cent., showing a fair increase in takings. The Smaalens railway shows the greatest improvement in income, but the shareholders have to be satisfied with 0·8 per cent. dividend. The Christiania-Drammen railway pays its shareholders a dividend of 1 per cent., and the Drammen-Skien Railway, which is the only line showing a decrease as compared with the previous year, only sees its way to ¼ per cent. dividend. The Drammen-Randsfjord line shows steady progress, and the shareholders receive a dividend of 2·8 per cent. The Jäder railway shows a small surplus, which has been utilised to reduce the previous deficiency. The Bergen-Voss railway shows an improvement as compared with previous years, but no dividend was declared. It will be seen from these particulars that there is ample room for further improvement so far as the majority of the Norwegian railways are concerned, but as several of the more important industries of Norway are showing themselves capable of considerable development, such increase in traffic may be looked forward to with a certain amount of confidence.

EXPORT OF ICE FROM NORWAY.—The export of ice from Norway shows, as might be expected, a steady increase, as the consumption, no doubt, becomes greater and greater in various industries. The exports during the past years are estimated at—

290,000	register	tons	during	.....	1889
244,000	,,	,,	,,	.....	1888
266,000	,,	,,	,,	.....	1887
254,000	,,	,,	,,	.....	1886
228,000	,,	,,	,,	.....	1885

The economical result of last year's ice shipping is also considered satisfactory. Prices were in February 4s. per ton f.o.b.; they then declined to 3s. 6d., rose during July and August to 4s. 6d.-5s., but declined again to as little as 2s. in October-November.

EXPORT OF TIMBER FROM NORWAY.—The past year has been a good year for the Norwegian timber industry, and the best hopes are entertained as to the future. Last shipments will probably exceed those of the previous year by about 5 per cent. The export during the first ten months of last year shows that England headed the list of customers with 1,119,827 cubic metres, the next being France with only 154,029 cubic metres.

THE SPIRIT INDUSTRY IN RUSSIA.—As the export premium on refined spirit has not brought about the expected increase in the export the Government has decided to grant a premium in the refining itself, which will be paid to the producers of refined spirit for the loss of spirit through the refining process. This system will, it is anticipated, encourage the home industry in various ways.

THE PAPER INDUSTRY IN SWEDEN.—The stagnation which has been prevailing for several years in the Swedish paper industry was last year transformed into a very considerable activity, so that the mills could hardly keep pace with the demand. A result of this better feeling has naturally been an extension of old mills and the erection of new works. At the same time the German competition is apparently becoming keener, and the Germans seem able to undersell the Swedes.

MADRID, 20TH JANUARY, 1890.

QUICKSILVER IN SPAIN.—The production of quicksilver in the Almaden mine for the year 1889 has been 49,477 flasks, as compared with 53,109 in 1888. The diminished production is not to be attributed to any other cause but to the mistake of the Government in the administration—viz., in placing the management of the mine in the hands of the administrative employers instead of leaving it to the engineer. The mistake was so great that it was soon found out, and it had to be corrected almost at once; the want of technical knowledge on the part of the "red tape" parties hindered everything.

THE EXPORT OF PIG IRON FROM BILBAO.—The export of pig iron from Bilbao to foreign markets during last year was only 73,524 tons. Of ores England and Scotland took 2,770,125; Germany, 740,000; and France, 378,347 tons.

IRON ORES AT BILBAO.—It is wonderful how persistently every piece of ground in the vicinity of Bilbao, within eight or ten miles, is taken possession of on account of the supposed iron ore mines underneath. It seems very likely that it will result in a great waste of money in the majority of cases.

ANTIMONY ORE.—The engineer of the Zalamea prospecting company reports that in a recent visit to the spot he has found in the antimony lode of the mine "La Moderna," a vein of nearly pure sulphuret of antimony of 2ft. in thickness.

THE TRANSATLANTIC STEAMSHIP COMPANY.—The Transatlantic Company, who own a very large number of steamers, and who have the entire contract with the Government for carrying the mails, have printed their report and balance-sheet for the last year. The company has not been paying a dividend for five or six years, and, according to the report, some years more will pass before the profits can be devoted to such a purpose. In the meantime private lines of steamers are competing with those of their fleet with regard to the American ports, and altogether the appearance of the business of the Transatlantic Company does not look reassuring.

NEW YORK, 11TH JANUARY, 1890.

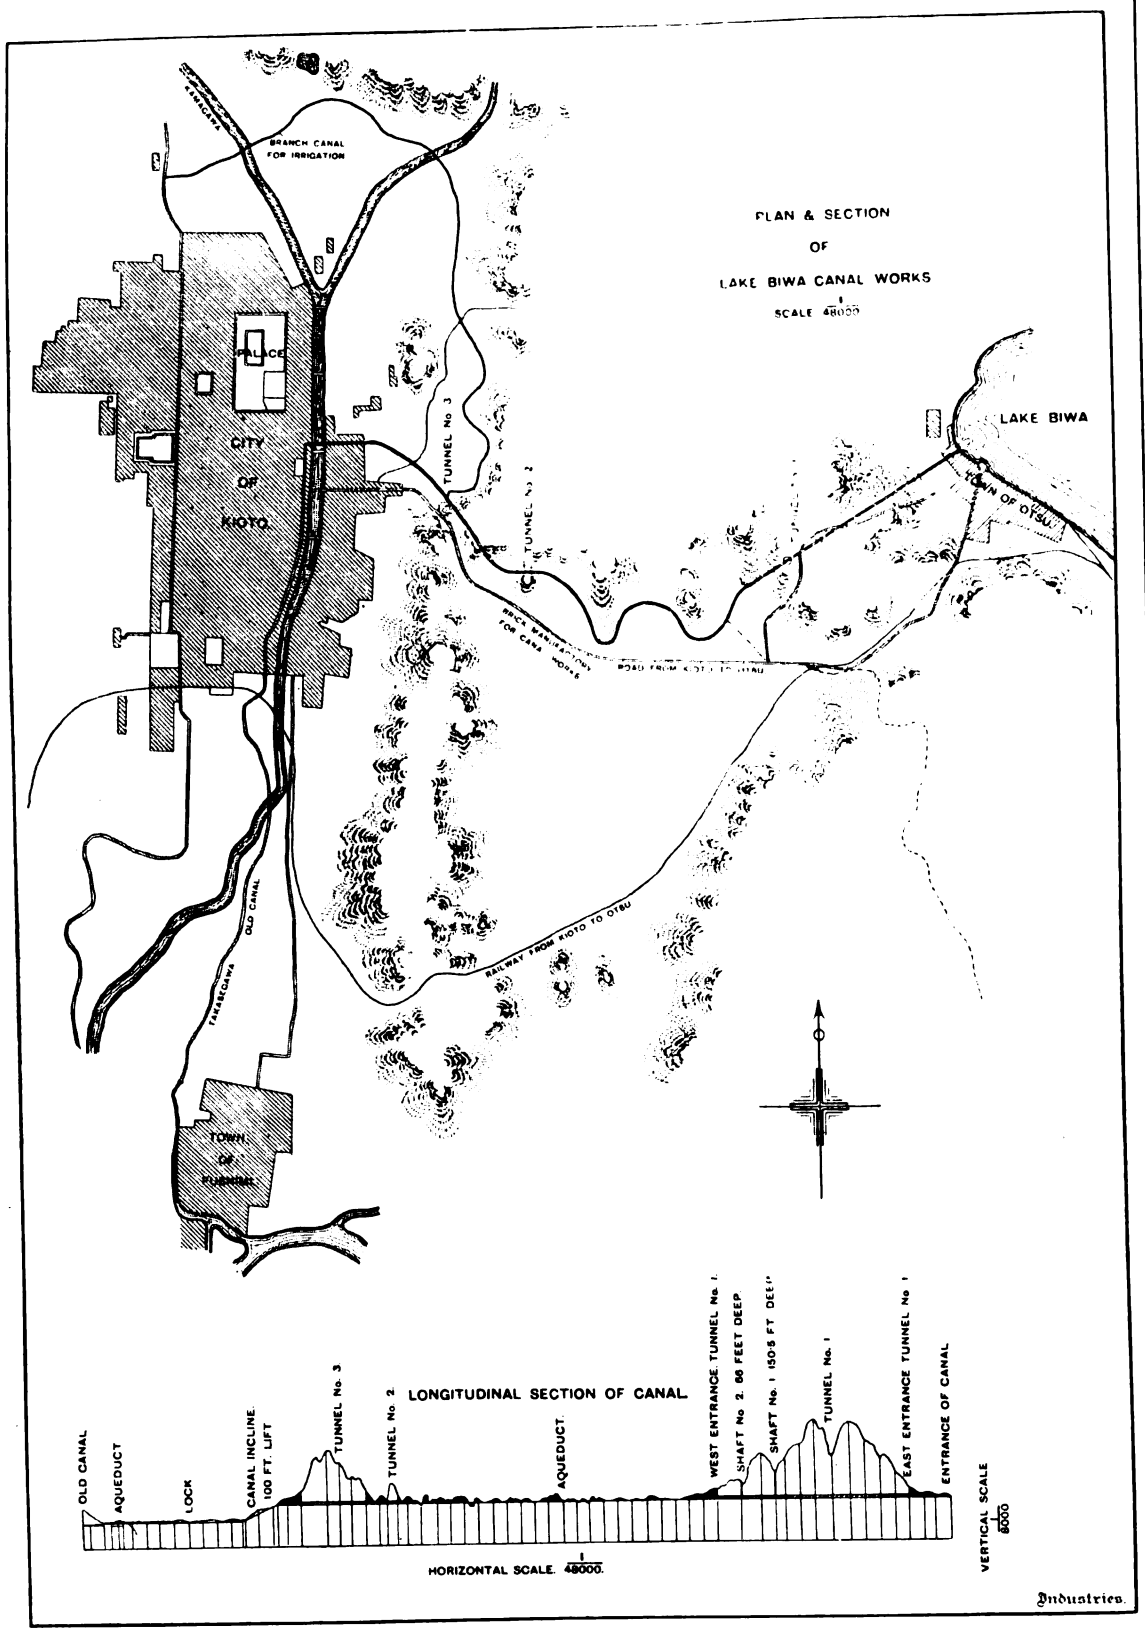
THE COAL MARKET.—The demand for anthracite is dull. There is still no demand for domestic sizes, and the boom in iron keeps up some activity in manufacturing sizes, though this affects the retail business but little. Reports from almost all the selling centres are discouraging. Many of the principal agents are discounting a winter without any cold weather, and are cutting down expenses until spring. A few have closed their offices and suspended their travelling agents, and more are talking of doing the same thing. The supply of bituminous is still less than required, and prices are varying considerably in consequence.

THE IRON AND STEEL MARKET.—The new year opened with iron and steel in a better condition than was ever known before. The price of iron is not only high, but the amount produced is enormous. Our markets are being practically supplied by our own furnaces, and the price of iron is as low at some of them as in Great Britain, while steel rails are the same price here as abroad. The market for pig iron is distinctly dearer, and while quotations are nominally $18, $19, and $20, at tide, it is almost impossible to place a fair-sized order without paying a half-dollar per ton advance, and there is every prospect of this amount being doubled in a few days. Materially more advantageous prices are not looked for, as the present advance no more than offsets the recent advances in fuel, freight, ores, &c. The actual gain as compared with this time last year is about $2 per ton, and from the lowest prices ruling during the year from $3 to $3·50, but were it not for the enormous development of resources during the last few years prices would have gone much higher. In manufactured iron business has hardly commenced yet, although most of the leading mills resumed work on the 6th inst. The feeling as regards prices is very firm, and full quoted rates are demanded on new business. The demand is not very heavy, as the majority of large consumers have already placed their orders for January and February delivery. Prices are firm at 2c. per lb. for bars, 2·35c. for iron plates and angles, and 30c. to 40c. more per hundred pounds in steel. The demand for steel rails is not large, although there is no scarcity of work. Prices for rails are $35 per ton at mill. The demand for steel in other shapes is very heavy, and more than offsets any dulness in other departments. Billets are nearly a dollar dearer, $38·50 to $39 per ton delivered being inside quotations.

THE METAL MARKETS.—The copper market has been quiet, but prices are well maintained. Lake copper for January delivery is quoted at from 14·40c. to 14·50c. per lb., while casting brands are worth 13c. Tin has been dull, spot selling at 21·20c. per lb. The plate trade has been the dullest known for a long time, as practically nothing has been doing. Lead is inactive, and is quoted at 3·90c. to 3·92½c. per lb. There has been considerably more activity in spelter; prices are slowly rising, closing quotations being 5·45c. per lb. Antimony is a little more active, and prices are steady.

A NEW FREIGHT LINE.—The sailing of the steamship "Brookfield" marked the second move in the development of the Reading Railroad's project to establish a Transatlantic freight line from this port. The Reading proposes to furnish better ocean facilities, not only for local shippers, but for general merchandise from the West, which can be obtained by its new York and Erie connections and through an agreement with the Baltimore and Ohio. There is a large river frontage at Port Richmond which is controlled by the Reading Company, the wharves of which have heretofore been allotted to individual coal operators. A consolidation of these privileges will leave ample wharfage for the new freight line. The first of the line sailed on December 10th; the "Gordonia" will sail on January 27th; and the "Ambassador" on February 20th. The company proposes chartering vessels coming here to unload, and send them away with a full cargo, intending to employ most of those coming from the Mediterranean with iron ore.

A NEW ROUTE TO NEW YORK.—Preparations are being made to run an experimental train over the Baltimore and Ohio's new road from Bound Brook to Kill von Kull. The company has had considerable trouble in building this road, and it has been able to complete it only after a number of lawsuits have been decided in its favour. A number of drawbridges had to be built, and owing to the wet weather and high tides construction has been considerably delayed. The bridge across the Kill von Kull is being pushed forward as rapidly as possible. Cofferdams are now erected, and bulwarks and piers are being extended into the water. When the bridge is finished across the Kill a through route will be opened to Staten Island, and passengers will be transported to New York by boat.



CHICAGO'S ELEVATED ROAD.—The franchise granted by Chicago for an elevated railroad through the south division is believed to be in reality intended to furnish terminal facilities in the heart of the city for one or more Eastern trunk lines. Negotiations, it is said, have been in progress with the Canadian Pacific and the Baltimore and Ohio Roads. It is intimated that the former, should it be able to secure this entrance into the city, would build a line across the State of Michigan to a connection with the elevated road at the Indiana State line.

AN EXTENSIVE STEEL PLATE CONTRACT.—One of the largest contracts for steel ship plates ever made in America was concluded a few days ago by the American Steel Company with a representative of Mr. Andrew Carnegie. The contract calls for above 5,000 tons of steel plate, amounting to over $300,000. It will furnish plates enough for seven steel vessels to be built during the coming year at Duluth, Minn. An option was given for steel enough for three more vessels, and this will probably be closed in a few days, making the entire order 7,200 tons.

KANSAS SUGAR.—The State sugar inspector of Kansas has filed his annual report concerning the sorghum sugar industry in Kansas. The grand total of the sugar manufactured this year was 1,293,275lb., as against 693,274lb. manufactured last year. In addition, the inspector states that fully 200,000lb. more sugar will be obtained from the "second," which will take a month or six weeks longer to get out.

A NEW JAPANESE CANAL.

A NEW JAPANESE CANAL.

THE important works which have been carried on for nearly five years under the charge of Mr. Tanabe Sakuro, a distinguished graduate of the Imperial College of Engineering, Tokio, for connecting the city of Kioto with Lake Biwa, and thus opening up a waterway direct to the sea at Osaka for a very important district in Japan, are now approaching completion, and a more detailed description of them than we gave in our recent review of canal engineering for the year just closed may interest our readers, not only on account of the works themselves, but also because they afford an example of what is being done by the young Japanese engineers who have received a good training in Western methods. The map given above shows the district between Lake Biwa and Kioto, and the line of the canal, which joins an older one at Kioto, which again is connected with the river called the Kamagawa, leading direct to Osaka. The longitudinal section shown is that between Lake Biwa and the old canal, and gives some idea of the work involved.

The proposal to construct a boat canal from Lake Biwa to the Bay of Osaka is a very old one, dating as far back as the twelfth century, when Kioto became the chief seat of the Central Government. Up till 1868, when the revolution occurred which overthrew the feudal government and restored the Mikado to his position as actual as well as nominal head of the Government, the matter had not got beyond the proposal stage. Since that event, and in consequence of the seat of the Government having been removed to Tokio, it became necessary to take steps to fill the void thus caused by creating industries and encouraging trade and commerce, and this has been done with very considerable success. There is a railway from Kobe direct to Kioto, with connections in various directions, and commerce has developed to a very considerable extent, while many new industries have been started and old ones revived. It was felt, however, that something else was wanted in the way of water-carriage, and in 1885 the canal we are about to describe was commenced, chiefly through the efforts of the present governor of Kioto, Mr. Kitagaki, and it is now almost completed. In addition to providing a waterway from Lake Biwa to Osaka Bay, it will also supply water power for manufacturers, irrigation for rice fields, and such water works as are necessary for sanitary improvements.

Lake Biwa is the largest lake in Japan, having an area of nearly 500 square miles, and it lies at a height of 280ft. above the sea level. It is distant from Kioto, at the point where the canal joins it, $6\frac{7}{8}$ miles, and on that length there is a fall of 143ft. The entrance to the canal from the lake is being formed by reclaiming about 1,000ft. of the lake, and forming a breakwater to protect it and ensure still water within. The material for these works is the *débris* from the canal and the tunnel. From this point there is a stretch of 600 yards of open canal, varying in breadth from 28ft. to 19ft., and with a depth of 5ft., and it is provided with a regulating lock and sluice gate, by which the flow through the canal is maintained constant at the rate of 300 cubic feet per second. Then comes tunnel No. 1, which is 2,680 yards in length, and is the second longest in Japan. It is of horseshoe section, with a breadth of 16ft. and a height of 14ft., of which 6 is the depth of waterway. It passes through the range of Nagarayama, consisting of clay, slate, hornstone, sandstone, quartz, porphyry, and is being lined throughout with masonry and brickwork. There is no tow-path, the canal boats being intended to be drawn by a chain. The canal was laid out very correctly, as the headings met almost exactly, a feat of which Mr. Tanabe, the engineer-in-chief, has reason to be proud. From the lower end of the tunnel there is a stretch of open canal of about three miles, sometimes in cutting and embankment, but mostly in the form of a trough along the hill slope, where the outer portion is in many places more or less partly formed by artificial embankments. Thence to the basin of Kioto there is a range of hills, called Hino-oka-yama, which is pierced by tunnels No. 2 and 3, of 137 and 934 yards in length respectively, and of the same shape and dimensions as No. 1. Just below No. 3, at a distance of about $5\frac{1}{4}$ miles from Lake Biwa, the canal is divided into two. One branch, which is designed for navigation, descends about 120ft. in a distance of 1,800ft. to the plane of the city, a slope of 1 in 15. The boat traffic at this point is worked by an inclined plane, the boats being put into a wheeled cradle, which is pulled up and let down by means of a wire rope worked by the water power from the canal above. From the foot of this plane there extends a stretch of canal 60ft. wide and 5ft. deep, for a length of a mile and a quarter, and it then joins the Kamagawa—the river which provides the existing waterway to Osaka Bay. Between the canal and the river there is a regulating lock. The total length of the main canal is thus $6\frac{7}{8}$ miles, and the slope ranges from 1 in 2,000 to 1 in 3,000, excepting the incline already mentioned, and the lower reach of the canal, where it is almost level.

The second branch of the canal, from the fork at the head of the incline, leads northwards through a tunnel 150 yards long, and winds along the face of the hills, and then crosses the valley of the Imperial Tombs by a handsome aqueduct 300ft. long and consisting of fourteen arches, passes through another hill by means of a tunnel 200 yards long, crosses two rivers—the Takano and the Kamo, 160 and 150 yards wide respectively, and terminates at Kogawa, the north extremity of the city of Kioto, the length of the branch being $5\frac{1}{4}$ miles. This branch is intended chiefly for irrigation and for water power, and will be used for many manufacturing purposes. It is intended to utilise it largely for generating electricity, which may be distributed to different parts of the town, for lighting, propelling cars, &c. In these respects some of the Japanese towns have made much more progress than people in this country imagine.

The total estimates for the works amount to a million and a quarter silver dollars. Of this about one-third was a gift from the Emperor, and a quarter from the Central Government, while the remainder is to be raised by local taxation of Kioto and neighbourhood. When the work has been completed it will do much to further the trade and commerce of Kioto, and its design and execution reflects much credit on Mr. Tanabe Sakuro, the engineer-in-chief.

WE have received the Telegraph Manufacturing Company's Wire Catalogue. Besides prices of wires and cables, the catalogue contains a large number of tables of resistances, and of useful formulæ for quickly finding the sizes of wire needed for any work.

MESSRS. ARCHIBALD SMITH & STEVENS, hydraulic engineers, Janus Works, Battersea, have forwarded us their new illustrated catalogue of self-sustaining lifts and hoists. Several improvements have been introduced into their apparatus lately.

THE "PRACTICAL ENGINEER" POCKET BOOK AND DIARY.—We have received a copy of this little annual for the present year, and we can strongly recommend it to our engineering readers. It is arranged in a handy form, and contains a large amount of information of daily use to the engineer in a very concise and convenient shape. At the end of this book is a useful diary.

Market improving.

PIG IRON—BRAND "CARRON."

Present prices of "Carron" Pig Iron are as follow:—

	No. 1.	No. 3.
Prices, per ton ...	81/-	74/-

F.O.B. Grangemouth or F.O.R. Carron Works, Stirlingshire.

Terms: Cash on 10th of Month, following delivery.

	Per Ton Extra.
Delivery at Leith or Granton	1/9
Do. at Broomielaw, Glasgow	2/-
Do. at London (over ship's side in Thames)	6/-
Do. at Liverpool (alongside export vessel)	—
Do. at do. (traders' dock)	—
Do. at Hull (on quay)	5/-

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

	Com. £ s. d.	Best. £ s. d.	
Middlesbro' Bars	8 2 6	8 12 6	f.o.t. wks.
„ Angles	7 17 6	8 2 6	„
„ Plates	8 5 0	8 15 0	„
Staffordshire Bars	9 7 6	9 17 6	London.
„ Angles	9 7 6	9 17 6	„
Crown Sheets	9 0 0	9 10 0	„
„ Hoops	8 10 0	9 0 0	„
"Siemens-Martin" Steel Boiler Plates		10 5 0	„
„ Ship and Girder		9 5 0	„

Market steady; prices firm.

METALS.

Spelter: Ordinary	£25	7	6	to	£25	10	0
Copper: British Cakes and Ingots	58	0	0	„	59	0	0
„ Chili Bars, G.O.B.'s	49	5	0	„	.....		
„ Other sorts, G.M.B.'s (equal to Chili Bars)	49	5	0	„	.....		
„ Manufactured (strong)	66	0	0	„	.....		
Lead: Common Pig	15	12	6	„	15	17	6
„ English Sheet	16	2	6	„	16	7	6
Tin: Straits	94	0	0	„	94	10	0
„ Australian	94	5	0	„	94	15	0
„ English Ingots	99	10	0	„	100	0	0

Messrs. Carrick & Brocklank, Manchester, report as follows:—

COPPER: The high rate of discount keeps copper slightly depressed, though the market closed firmer yesterday. Forward Chili bars are worth £49 15s. to £50. Manufactured copper is still quite firm at £66 for sheets and £69 for bottoms, and all the manufacturers are extremely busy.

TIN is practically unchanged, but it is worth a trifle more than when we last wrote. There is a good business doing in English tin.

LEAD is slightly lower, although a considerable business has been done during the last fortnight.

SPELTER: There is a good demand for this metal, and the price is well maintained; nevertheless, there is a little weakness, probably in sympathy with other metals generally.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—The position in the alkali markets is hardly so healthy now as last week. Bleaching powder has given way somewhat, and though the high prices for caustic soda are maintained, supplies being so limited, there are few buyers. Soda ash continues scarce, makers being fully engaged for some weeks ahead, and higher prices are being asked for soda crystals. The excitement in acetate of lime has somewhat abated, but the position is very firm; acetate of soda is, however, dull; acetates of lead steady. All carbolic acids are quiet. Benzoles are tending upwards. Solvent naphtha and creosote are moving off briskly. Sulphate of copper is scarce on spot, and little obtainable for next month.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, Jan. 23.—*Iron.*—The market here is quiet, and the prices of bars and joists rarely rise above 160s., though quoted 168s. in the official lists. The demand has slackened a little in the Haute-Marne. In the other markets of the provinces the current of business is brisk, and everywhere prices are firm. Plates are much sought after. In the Nord bars and joists are quoted by some manufacturers 160s.

Metals.—The "booming" tendency of the metal market has run itself out, and a reaction has set in. Copper has lost some of last week's advance, Chili bars being now quoted £54. Tin prices have given way considerably, Banca being quoted £103, and Straits £100. Lead has receded to £14 8s. free at Havre. Spelter maintains its ground, Silesian being firm at £26 delivered at Havre.

BERLIN, Jan. 23.—*Metals.*—The metal market is moderately active. For copper prices tend in favour of sellers, Mansfeld refined being quoted £61 to £62 10s.; but tin has given way, and still shows a declining tendency. Banca is quoted £104 to £106. Lead is firm at last week's prices. The same may be said of spelter. For antimony regulus the market remains unchanged.

BRESLAU, Jan. 23—*Iron.*—The base price for bar iron has been advanced to 210s. a ton. Boiler plates and thin sheets are also quoted higher, the former selling at 250s., and the latter 260s., a ton. The demand is strong for all classes of iron. The blast furnaces are now working more regularly.

Zinc.—The zinc market is somewhat disturbed by a partial strike among the zinc workers of this district for an advance in wages. Their demands have been in part conceded. Spelter prices are, for the W. H. brand, 505s., 500s.; refined, 480s., 476s.; ordinary, 476s., 420s., according as the dates for delivery are less or more distant. Zinc dust is quoted 410s. to 420s.

Paper Prices.—At a meeting of the members of the Silesian and Saxon Papermakers' Convention, held in Dresden, it was resolved to make a considerable advance in the prices of printing and writing papers to cover increased cost of production due to higher wages and dearer coal and raw materials.

DÜSSELDORF, Jan. 23.—*Coal.*—The coal market is again disturbed by the prospect of another strike of colliers, the latter having given notice, through their representatives, that after February 15th they will demand a 50 per cent. rise in wages. The quotations for coal to-day do not materially differ from those of a week ago. Within the last eight or ten days a large quantity of coal has been sold for export to Belgium.

Iron.—The price of spiegel pig has been advanced 1s. a ton. The demand for forge pig is very brisk, but foundry is less inquired after. The market is very active for finished iron and steel. Bars, angles, and hoops are a little dearer. The following are the latest quotations: Ordinary spiegel pig, 103s.; Rhenish-Westphalian forge, 92s.; Siegen forge, 93s.; foundry No. 1, 102s.; Thomas, 82s.; Bessemer, 93s. to 96s.; bars, 205s.; angles, 215s.; hoops, 212s. 6d. a ton.

HAMBURG, Jan. 23.—*Nitrates.*—The market is dull for Chili saltpetre, and prices are weak. Spot goods are offered at £8 2s., and February and March arrivals at £8 3s.

BRUSSELS, Jan. 23.—*Bourse.*—Industrial securities have fallen heavily within the last few days, and the downward movement continues. The drop has been greatest in the shares of the colliery companies, but iron and steel shares have followed at not long intervals. Shares in glassworks have, however, held their position in the market. These changes are a significant commentary on the industrial events of the last few weeks.

CHARLEROI, Jan. 23.—*Iron.*—The current of business in the iron market is greatly obstructed by the uncertainty of the coal supply. Naturally prices tend upwards, but sellers are reluctant to enter into fresh engagements. Dealings are most active in plates, which are very firm at 184s. a ton for the No. 2 quality.

Glass.—The production of the glassworks is greatly restricted by the want of fuel. A further advance in the price of glass to cover the increased cost of coal is under consideration, and will probably be agreed to within the next few days.

GHENT, Jan. 23.—*Flax and Yarns.*—The market is now well supplied with home-grown flax, and the demand is brisk. Prices remain unchanged. There is but little doing in Russian flax. The demand for yarns is slack, but prices are firm both for flax and cotton.

English Coal.—A firm of English coal importers is offering Welsh coal at 22s. 6d. to 23s., Newcastle coal at 19s. 4d. to 20s., and Scotch coal at 18s. 6d. a ton. A large trade is being done at these prices, Belgian and French coals being scarce.

SHIPBUILDING NOTES.

ON the 16th inst. Messrs. Russell & Co., Port Glasgow, launched the "Glen Cona," a large four-masted sailing ship of 2,500 tons net register. Her dimensions are:—Length, 213ft.; width, 42ft.; depth, 24ft. 6in.

ON the 21st inst. Messrs. Richardson, Duck, & Co. launched from their yard at Stockton an iron screw-steamer of the following dimensions, viz.: Length over all, 280ft. 3in.; breadth, extreme, 36ft. 6in.; depth, moulded, 19ft. 1½in. This steamer, which has been built to the order of Messrs. Burdick & Cook, of London, is classed 100 A1 at Lloyd's, and has been built under special survey. She has a short break poop, raised quarter-deck, long bridge from after end of engine room to foremast, topgallant forecastle, and cellular double bottom fore and aft for water ballast. Her engines are by Messrs. Blair & Co., Ld., and have cylinders, 21½in., 35in., and 57in. in diameter, by 36in. stroke. As the vessel was leaving the ways she was christened the "Eugenie."

WE have received a copy of a new catalogue which is now being issued by Messrs. R. E. Crompton & Co., Ld., Chelmsford. The book is got up in exceptionally good style, and is full of the very best photo-engravings of the various machines and apparatus manufactured by this well-known firm.

HOME INDUSTRIES.

LONDON 23rd January, 1890.

THE MONEY MARKET.—While the money market remains firm, the fear of gold withdrawals keeping it stiff, the competition among discounters for the few bills which are offered has led to a slight falling away in discount rates. There is no actual change in the monetary position. The dearness of money continues to restrict dealings on the Stock Exchange, but there have been a number of important movements. The most pronounced have occurred in South American securities, a sudden drop in the premium on gold at Buenos Ayres having given a fillip to all Argentine stocks. Brazilians, too, have improved, as the progress of time does not reveal any immediate likelihood of political or financial disturbance. Still, unless the decree relating to foreign capital in Brazilian enterprises can be explained away, as most of the reported eccentricities of the Provisional Government have been, an awkward time may be in store for shareholders in industrial undertakings in the new republic. Another movement in foreign stocks of some interest is the rise in Egyptians, owing to the approach of an agreement with France with regard to the conversion of the privileged debt. The market for home railway stocks has been uncertain, and the movements have been of little account. American railways have been firm, but Canadians are hardly in such favour as they have been. An unexpectedly good traffic return on the Mexican Railway has led to a rally in the securities of that line. Nitrate shares are still falling, and mines are a weak market.

COMPANIES.—The following companies have been registered since our last report:—Fraser & Chalmers, Ld., with a capital of £525,000, to carry on the business of mining machinery manufacturers; Aqueous Works and Diamond Rock Boring Company, Limited, with a capital of £25,000, to acquire certain patents; The Clutha Gold Mines, Ld., with a capital of £100,000, to acquire mines, &c., in the Transvaal; Argentine Inter-Provincial Railway Company, Ld., with a capital of £1,200,000, to construct, &c., railways in the Argentine Republic; La Plata Mines, Ld., with a capital of £100,000; The Louis d'Or (Main Reef) Gold Mining Company, Ld., with a capital of £80,000; The Jerram Sewing Machine Company, Ld., with a capital of £4,000; Fowler, Lancaster, & Co., Ld., with a capital of £22,000, to carry on the business of electrical engineers; The Caribbean Syndicate, Ld., with a capital of £20,000, to acquire lands, &c.; Kilburne Colliery Company, Ld., with a capital of £20,000; Fry, Janson, & Co., Ld., with a capital of £20,000, to carry on the business of ironmasters, general engineers, &c.; The Danube Bridges and Kustendje Harbour Works Company, Ld., with a capital of £500; The London Paper Mills Company, Ld., with a capital of £75,000; New Asbestos Company, Ld., with a capital of £120,000; The Glyncorrwg Colliery Company, Ld., with a capital of £200,000; The English Lager Beer Brewery, Ld., with a capital of £100,000; South Metropolitan Brewing and Bottling Company, Ld.; The Bristol Channel Steam Tug Owners' Association, Ld.; The Minerals and Fuller's Earth Syndicate, Ld., with a capital of £2,000; The Anglo-Dutch Borneo Goldfields, Ld., with a capital of £60,000; The Anglo-Dutch Borneo Diamond Fields, Ld., with a capital of £60,000; The Harmony Goldfields, Ld., with a capital of £1,000,000; The Globe Mill Company, Ld., with a capital of £140,000, to acquire certain patents; The Cantabrian Copper Mines, Ld., with a capital of £100,000; The Electrical Engineering Corporation, Ld., with a capital of £150,000; The Posman Syndicate, with a capital of £25,000, to prospect, examine, and explore countries; The Southern Africa Syndicate, Ld., with a capital of £1,000, to prospect, examine, and explore in South Africa.

ENGINEERING.—It will be remembered that some eighteen months ago we mentioned that a great increase in their business had made it necessary for Messrs. Davey Paxman & Co. to enlarge their works, and that new and large buildings were erected to take the place of the old pattern shop, which was then cleared and added as an extension of the foundry. We are glad to be able again to note that this firm is extending its works still further, and is again adding to the foundry and its already very large boiler shops.

SHIPPING.—Freights have shown a firmer tone, and rates have advanced. American business has been large, at the full advance for January and early February loading, but the demand has fallen off for later dates. A large fleet of steamers has been chartered for grain, general cargoes, and cotton, besides a few oil boats. Coal prices continue very high, and great difficulty is experienced in obtaining coals for bunkers or cargo. In shipbuilding activity prevails, and orders are booked from week to week, but in small numbers, as prices keep beyond the ideas of prudent owners, and considering the heavy increase made in the tonnage afloat during the past two years, the probable decrease of earning power, and present increase of working cost, there exists little encouragement to order new boats. The work secured by builders will keep them busy well into the third quarter of the year. Good second-hand boats are still inquired for, but at less money.

THE NAVY.—Messrs. Richard & Henry Green have received an order from the Admiralty to construct a steel steam water-tank and fire-float vessel for service at Sheerness Dockyard. She is similar to two steamers already built for the Admiralty, and will be placed on her station at the end of the present year. The machinery and pumps will be supplied by Messrs. Hawthorns & Co., of Leith.

INDIAN STATE RAILWAYS.—The Secretary of State for India is advertising for tenders for ironwork and steelwork for roadway bridges for Bibinani Crossing, Bolan Road, Beluchistan. Tenders will be received up to the 28th inst. The present requirements are 8 spans of 77ft. 6in. in the clear, 2 spans 23ft. in the clear, and certain additional ironwork at the connections of some of the spans, including all rivets, bolts, nuts, &c., required to complete the erection of the bridges in India, together with an allowance for waste, &c., of 10 per cent. of bolts and 50 per cent. of rivets on the net quantities required. The 77ft. 6in. spans consist of two lattice main girders 8ft. 9in. deep, cross girders, and trough flooring, together with fenders at the sides of road, handrail standards, and handrails. The smaller spans consist each of four 16in. rolled joists carrying trough flooring, fenders, and handrails. The larger spans are carried on expansion rollers of Bessemer steel supported on cast iron bedplates. All holes, which are to be riveted in India, are drilled. The contract includes three sets of hand-made tracings as the work is constructed. The approximate weight of one span of 77ft. 6in. is 53¼ tons, and of one 23ft. span 8¼ tons. Quick delivery is desired, and the contractor must state the time in which he undertakes to complete. Prices to be for delivery f.o.b. London, Birkenhead, and one other port to be named by contractor.

CYCLE SHOW AT THE CRYSTAL PALACE.—The Thirteenth Annual Exhibition of Bicycles, Tricycles, and Accessories, which will this year take place at the Crystal Palace, opens to-morrow, the 24th inst., and promises to eclipse all its predecessors as regards the number of machines to be shown. Not only will the entire floor of the Palace and courts be covered by exhibits, but this year the large Concert Hall has had to be thrown open to this use; even then the space appears insufficient, as many manufacturers have been compelled to curtail their exhibits.

MANCHESTER, 23rd January, 1890.

AN IMPROVED GASHOLDER.—The members of the Manchester District Association of Engineers visited Northwich on the 19th inst., where a new gasholder had just been filled. The holder is made on a new principle—the invention of Mr. William Gadd, C.E., of Manchester—and entirely obviates the use of the columns ordinarily employed. Spiral ways or guides are fitted inside the well, and the bottom of the inverted portion of the holder is provided with runners, which press upon the guides. As the gas enters the holder it lifts the upper portion, which receives a spiral instead of the usual sliding motion. The Northwich holder is a two-lift one, each lift being 20ft., the diameter being 60ft. While it has been filled, the severe gales of the past few days have tested its endurance. The work has been carried out by Messrs. Clayton, Sons, & Co., of Leeds, to the designs of Mr. Thomas C. Newbigging, C.E., of Manchester.

THE SALT TRADE.—The exports of salt from the Cheshire district do not point to a great success of the Salt Union. They reached in 1889, 745,111 tons; in 1888, 1,022,334 tons; and in 1887, 994,726 tons. The falling off is general to all the large markets, but it is stated that a much better tone is now observable, and that the demand is much greater.

PREFERENTIAL CLAIMS FOR RENT.—At a conference of various Chambers of Commerce in the North held in Manchester, on the 21st inst., it was resolved that landlords should not have power of distraint for rent in advance, nor when more than twelve months in arrear, nor in case of bankruptcy. It was also agreed that the power of distraint ought not to extend to the recovery of any sum paid as rent for power or machinery; and that in case of bankruptcy the claims should rank in the following order: The costs of the petition and administration of the estate; the claims of the landlord subject to only six months' arrears and not to the hire of power or machinery, or to an amount beyond that realised by the distress and paid over after deducting the cost of any goods delivered to the tenant within three months of the petition. The claims of the general creditors are placed last, and the landlord can claim as such for such amounts as are not preferential.

LOCAL RAILWAY BILLS.—The various local railway bills have been advanced a stage by passing the examiners of the House of Commons. The North West Central Railway, to which we referred a few weeks since, has been lodged. The capital is fixed at £2,000,000, and the borrowing powers at £666,664. The new loop line of the Manchester, Sheffield, and Lincolnshire Railway Company, which gives them access to the station belonging to the Midland Railway Company, is making rapid progress. At the Manchester end some heavy bridge work will be requisite in order to double the existing viaduct.

THE IRON TRADE.—After the free buying of the last few weeks the market here is somewhat dull. The heavy fall in warrants, although undoubtedly speculative in character, induces buyers to postpone purchasing, and as makers are well filled with orders they are indisposed to offer iron at lower rates. The result is that little business is being done except in small lots. Finished iron is in better request and prices are fully maintained. Steel bars and forgings are also very well ordered, and there is a good trade being done in steel plates.

THE LINEN AND JUTE TRADES.—In the linen, as well as other departments of Manchester trade, the principal interest of the week has been centred in the great sale of heavy goods, formerly included in the stock of Messrs. Samuel Fletcher, Sons, & Co., which began on Monday, and was at its height on Tuesday. Buyers from all parts of the kingdom flocked to this city for the occasion, and a very extensive business resulted. Messrs. Rylands were the purchasers of the stock, which is variously estimated at from £30,000 to £40,000 in value. The home trade in linens keeps satisfactory, and a better demand has been noticeable of late. Nothing, however, of a definite nature can yet be said concerning the extent of the orders received, as we have not got into full activity. Prices keep firm, and linen threads sell well at the figures previously given. There is a good inquiry for jute fabrics, which sell extensively in this market.

GLASGOW, 23rd January, 1890.

PIG IRON.—This week has again been a disheartening one for holders of warrants. Daily the price came down under the pressure of heavy sales, till at last a number of holders began to feel that there must have been something wrong in their calculations, and the lower the price went the greater was their anxiety to get out. On Monday, the 20th, hematite and Cleveland experienced a fall of about 2s. 6d. per ton, Scotch giving way about 1s.; and the following day there was a further fall in every description of warrants, but things rallied fairly in the afternoon. On Tuesday the market was fairly brisk, and though at the opening of the market there was a good deal of selling, there was less disposition to break rates.

SHIPBUILDING.—The recent falling off in the number of new orders in the shipbuilding trade may, perhaps, be explained by the great decline which has taken place in colonial freight rates. In November, 1888, the rate from London to Melbourne was 63s. 6d.; the present rate is 40s. At the same date rates to the River Plate were 37s. 6d.; now they are 26s. 6d. Since November of last year Cape steam rates have fallen from 50s. to 39s., and in other directions there is a proportionate falling off. Under these circumstances shipowners can scarcely be expected to increase their tonnage.—Messrs. Denny Brothers have booked an order for a large steamer for the Union Steamship Company. The vessel will be similar to one now in the hands of the same builders for the same owners.—Messrs. W. B. Thomson & Co. have secured a contract to build a steamer of about 900 tons for Messrs. M. Langlands & Sons, Glasgow. The vessel is to be employed in their trade between Leith, Dundee, Aberdeen, and Liverpool, and is to be fitted with triple expansion engines and every modern improvement.

COALS.—Specifications are issued for contracts of over 103,000 tons of coals for the Swedish railways, consisting of about 100,000 tons of locomotive coal and 3,000 tons of gas coal, anthracite, &c. The coal is deliverable at the following Swedish ports: Stockholm, Göteborg, Malmö, Stugsund, Sundsvall, and Trondhjem. Lochgelly is the Scotch coal specified, while South Yorkshire, Edmonds, Wombwell, &c., and West Hartley, Davison's, Hastings, &c., are specified in English coal.

ENGINEERING.—A contract for 18,000 tons of cast iron pipes for Queensland, which has been in the market for some time, has been secured by Messrs. Robert Maclaren & Co., of the Eglington Iron Works. The goods will probably be shipped by the Shire line of Messrs. Thomas Law & Co.

THE FORTH BRIDGE.—The Forth Bridge was tested on Tuesday, a train weighing 2,000 tons being run over it slowly. The train was composed of 100 loaded coal waggons.

LABOUR.—Another agitation among the sailors and ship hands generally on the Clyde, for a further increase in wages, is on foot. An advance of 5s. per month has been conceded to the firemen on some of the lines, and this has apparently suggested a demand by the seamen for a similar rise. These demands are being granted in several instances.

THE EDINBURGH EXHIBITION.—The committee of the Exhibition are prepared to consider tenders for the working of the electric railway which they have decided to lay down in the grounds. The railway will be used for many practical purposes, and not merely as a show piece.

(From our own Correspondents.)

LIVERPOOL, 22nd January, 1890.

IMPORTANT DOCK IMPROVEMENTS.—At the last meeting of the Dock Board the Works Committee recommended the raising of the quay of the Queen's Dock, and the erection thereon of a single shed, at an estimated cost of £49,500. If the scheme is carried out, the depth of the water in the dock can be raised if necessary to 30ft. by means of the pumps at the Coburg Dock, which are used for this purpose in the system of the old South Docks. These pumps, with the present proposed outlay and the amount spent annually in the working of the pumps, represented a capitalised value of £175,000. The Committee further recommended the acceptance of the tender of the Linde British Refrigeration Company, amounting to between £5,000 and £6,000, for the supply of machinery for the new Woodside Foreign Animals Wharf, to be erected at a cost of about £10,000.

LARGE IMPORT OF FOREIGN CATTLE AND DEAD MEAT.—During the past week twelve steamers, from different ports in America and Canada, landed 2,435 cattle, 18,803 quarters of beef, and 60 carcases of mutton, showing an increase over the imports of the previous week of 1,312 cattle, 8,127 quarters of beef, and 28 carcases of mutton.

Digitized by Google

THE STRIKE IN THE GRAIN TRADE.—Owing to the strike of the grain carriers at the North and South Docks, large quantities of wheat remain on the quays, consignees being unable to find men to fill it in the bags. As a consequence, grain ships are now ordered to the Waterloo Dock, where different conditions of labour prevail, and which is consequently not affected by the strike. At the South Docks some of the men have resumed work at the former rate of wages, and it is thought that the strike will collapse within the next few days.

THE LIVERPOOL TRAMWAYS AND OMNIBUS COMPANY.—According to the half-yearly report of the directors, just issued, a dividend of 5s. per share is recommended, the gross profits (notwithstanding the increased expenditure in men's wages, Sunday labour, &c., amounting to from £5,000 to £6,000) amount to £25,561 for the six months. Better trade, good weather, &c., have done much to make a marked improvement in the traffic receipts.

SHEFFIELD, 22ND JANUARY, 1890.

NEW RAILWAYS.—The Manchester, Sheffield, and Lincolnshire Railway Company have commenced work upon a most important section of line from Beighton to Chesterfield, passing through Staveley. When completed, the line will prove of great service in further developing the deep coal seams of North Derbyshire. It will also tap the well-known Staveley Coal and Iron Company's works. This line will also serve several other collieries and works. Another important line already well advanced is the Dore and Chinley Railway, which is under the care of the Midland Company. The very heavy tunnelling and cutting through the Derbyshire rock is proceeding rapidly.

IRON AND STEEL TRADES.—There is no particular change to note at present. Local makers of bar and merchant irons are working to their full capacity. The steel casting manufacturers are well employed. Some good orders are to hand from the Tyne for ship scantlings. There is an excellent demand for steel for engineers' tools.

NORTH STAFFORDSHIRE, 22ND JANUARY, 1890.

THE IRON TRADE.—There seems somewhat of a lull in the trade, but it is regarded as being only of a temporary character. Makers have orders on their books to keep them going for many weeks. Specifications and new orders are not so plentiful however. There is no change in prices, bars selling at £9 10s. per ton.

THE MOSSFIELD COLLIERY EXPLOSION.—The inquest on the bodies of those killed in the recent explosion at the Mossfield Colliery is now being held, and is exciting the keenest interest amongst the mining population of this district. Every effort is being made by the coroner and the legal gentlemen engaged in the case to elucidate the whole of the facts, and, if possible, to arrive at the origin and cause of the accident. Explorations are still being conducted, but it seems unlikely that it will be practicable to enter the pit where the explosion is supposed to have originated for some time to come, and until this is done all the bodies cannot be recovered.

LEICESTER, 22ND JANUARY, 1890.

WOOL SPINNING AND YARN TRADES.—The local wool market remains quiet. The turnover is restricted, but both holders and users are sanguine that the late higher and firmer prices will continue. Though buyers are compelled to come into the market frequently, they are diffident of engaging in any speculative transactions to any great extent. Deep-stapled Leicesters, average quality, make up to 29s. per tod, and superior to 31s. 6d. per tod. Spinners are all fairly busy, but offers of new contracts are mostly at too low a price to be accepted freely.

HOSIERY TRADE.—Though there is an absence of wintry weather, the year's trade has opened well so far, and most departments of the trade are well off for business. The prospect of a good spring trade is very encouraging.

BOOT AND SHOE TRADE.—An excellent commencement of the year's business has been made. All the factories are in full work, and considerable difficulty is experienced in keeping the staffs up to the required strength. Orders are coming to hand freely, and the outlook for some time is very cheerful. Leather merchants are having a busy time. The turnover is good, and contract orders are freely booked. The market is firm.

CARDIFF, JANUARY 22ND, 1890.

COAL AND COKE.—The steam coal market is not quite so brisk, on account of the cessation of orders from Belgium, where the strike is at an end, but the general condition of the market is extremely healthy, colliery proprietors having as much as they can do to keep pace with the ordinary demand. The output is not as large as it might be, on account of the restriction to supply by the workmen, who are perhaps unwittingly the main factors in keeping capitalists from over-supplying the market, and are instrumental in keeping prices at their present high level. Prices are firm, steam coal, which a few years ago was sold as low as 7s. 3d., being now sold at 14s. First qualities are quoted at 16s. to 16s. 6d.; second, 15s. to 15s. 9d.; and third, 13s. 6d. to 14s. 6d. House coal finds a ready sale, and for coke the demand is extraordinarily active. Several cargoes of Welsh coke have been despatched to the West Cumberland ports for the blast furnaces in that district. This, in addition to a good demand from abroad, as well as for local consumption, keeps prices up. 25s. to 26s. at the ovens is readily obtainable for furnace coke, and foundry coke (Hood's) realises as much as 32s. to 34s. f.o.b.

IRON AND STEEL.—The inquiries for pig iron have not been heavy, but, as makers are all heavily sold, this seems to have no effect on the market, quotations for hematites being firmly maintained. It is generally expected that, on account of the violent fluctuations in the warrant market, there will not be much upward movement in prices during the remainder of the month, but when buyers can hope for a concession in price is difficult to indicate on account of the high prices demanded for coke, ore, &c. For steel bars the demand continues active, current quotations being £7 15s. to £7 17s. 6d. Steel rails show a steady improvement, and, on account of the stocks being almost exhausted, great difficulty is experienced by buyers in getting orders executed for slightly defective or odd parcels, which usually are a drug on the market. Amongst local iron and steel masters the question of fuel is not so important as it is in the Midlands and Northern districts, as almost without exception the large iron and steel manufacturers in the neighbourhood are the owners of extensive collieries, so it simply becomes a question of a reduced surplus of coal for sale on the open market. With regard to coke this is only partially the case, but where ironmasters do not make sufficient for their own wants they have taken precautions to secure the bulk of their supplies for the ensuing year from local coke makers. The scarcity of iron ore is, however, giving rise to serious apprehension. Ironmasters in this district are entirely dependent upon supplies from Spain, and although they appear to have covered themselves for more than half their wants during the ensuing year, speaking generally, they find considerable difficulty in getting delivery of what they have purchased. The sellers in Spain are using every endeavour to evade delivering the ore sold at low prices, and as the shipments from Bilbao are exceedingly small on account of the bad weather, it is clear that when the present stocks are exhausted some of the blast furnaces will have to be damped down on account of scarcity of ore. Meantime deliveries are being made from Benisaf, Carthagena, and Seriphos (Greece). At the last-named port an exceedingly lumpy and pure ore is being shipped, far superior to the Rubio and Campanil of Spain, which is deteriorating in quality. The red hematite ore from the Seriphos district contains only about 4 per cent. of silica, and is all lumps. Rubio ore is quoted at 17s. 6d. c.i.f. Cardiff or Newport, 18s. 6d. Middlesbrough, 18s. 9d. Glasgow, 18s. 6d. Ardrossan and Ayr, 18s. 3d. Tyne Dock, 18s. 6d. Bo'ness and Grangemouth, on the basis of 50 per cent. metallic iron. Seriphos ore is sold at 18s. 6d. Cardiff or Newport, 19s. 3d. Middlesbrough, 19s. Tyne, on the basis of 50 per cent iron and manganese. The freight market is inactive on account of the closing of the Black Sea and Baltic, but as chartering for those trades has now commenced there is every prospect of better business.

BARROW-IN-FURNESS, 22ND JANUARY, 1890.

IRON AND STEEL.—The positon of the hematite pig iron trade is more remarkable than ever this week. Warrants have been as low as 72s. 6d. and 73s. 6d., at which prices business has been done; but makers are quoting 82s. for mixed numbers of Bessemer iron and 81s. 6d. for No. 3 forge, and business has been done at these figures. There is no belief entertained in the permanency of the depression in warrants, and the action of the "bears" is unexplainable. In the meantime, however, there is an increase in stocks held during the week to the extent of 1,305 tons, but this to some extent is explained by the fact that speculators are buying at low prices and holding for better ones. Stocks have increased from the beginning of the year to the amount of 1,625 tons, and they now stand at 383,272 tons. Steel makers are exceptionally well off for orders, and prices are quoted at very firm rates. Heavy sections of rails are quoted at £7 5s. per ton, and light and colliery sections at £8 10s. Ship plates are in brisk request on local as well as on general account, as also are angles and other classes of steel shipbuilding material. The price of steel plates is £8 15s., and of angles £7 15s. per ton. Boiler plates are brisk at the advanced price of £12 5s. per ton. Blooms, slabs, billets, and tinplate bars are a very active trade at £7 per ton, while hoops have advanced to £10 10s.

SHIPMENTS OF IRON.—Shipments are shown to be on a smaller scale than last year. The pig iron shipments for last week from West Coast ports were 7,255 tons of pig iron and 8,839 tons of steel, a total of 16,094 tons, compared with 24,242 tons in the corresponding week of last year. The total shipments to date this year have been 51,238 tons, compared with 60,163 tons in 1889, a decrease of 8,925 tons.

MIDDLESBROUGH, 22ND JANUARY, 1890.

PIG IRON.—There is a great disturbance in the pig iron market. The "bears" have managed to pull down the prices, and the consequence is that hardly any business is being done. Merchants quote 58s. 6d., but makers will not quote below 60s., and most of them not even that. They have plenty of orders booked, and look for an improvement shortly. Warrants have been fluctuating from 57s. 6d. to 58s. per ton. Connal's store has not changed much during the week. On the 20th inst. the stock amounted to 183,508 tons, a decrease of 700 tons over the week. In hematite iron, East Coast brands are subject to fluctuation also. Nominally, they are 81s. per ton mixed numbers, but business has been done at 3s. per ton less.

SHIPMENTS OF PIG IRON.—The shipments of pig iron have fallen off considerably as compared with those of last year, but they are much about the same as those of last month. Up to the 20th inst. they amounted to 25,763 tons, as against 25,707 tons to similar date last month, and 41,857 tons to the 20th of January last year. The decline is in both home and foreign shipments. Of course the weather has been very stormy, but the Scotch shipments have been affected more by the ups and downs of the Scotch market.

MANUFACTURED IRON AND STEEL.—There is a much easier feeling in manufactured iron and steel. The work in hand is sufficient, but the outlook is not so encouraging. There is a lack of inquiry, and prices are not, therefore, so stiff. Iron ship plates are at £8; ship angles, £7 10s.; bars, £8 per ton, less the usual discount. Steel ship plates, £9; ship angles, £8 10s.; rails (heavy section), £7 per ton f.o.t. at works.

SUNDERLAND, 22ND JANUARY, 1890.

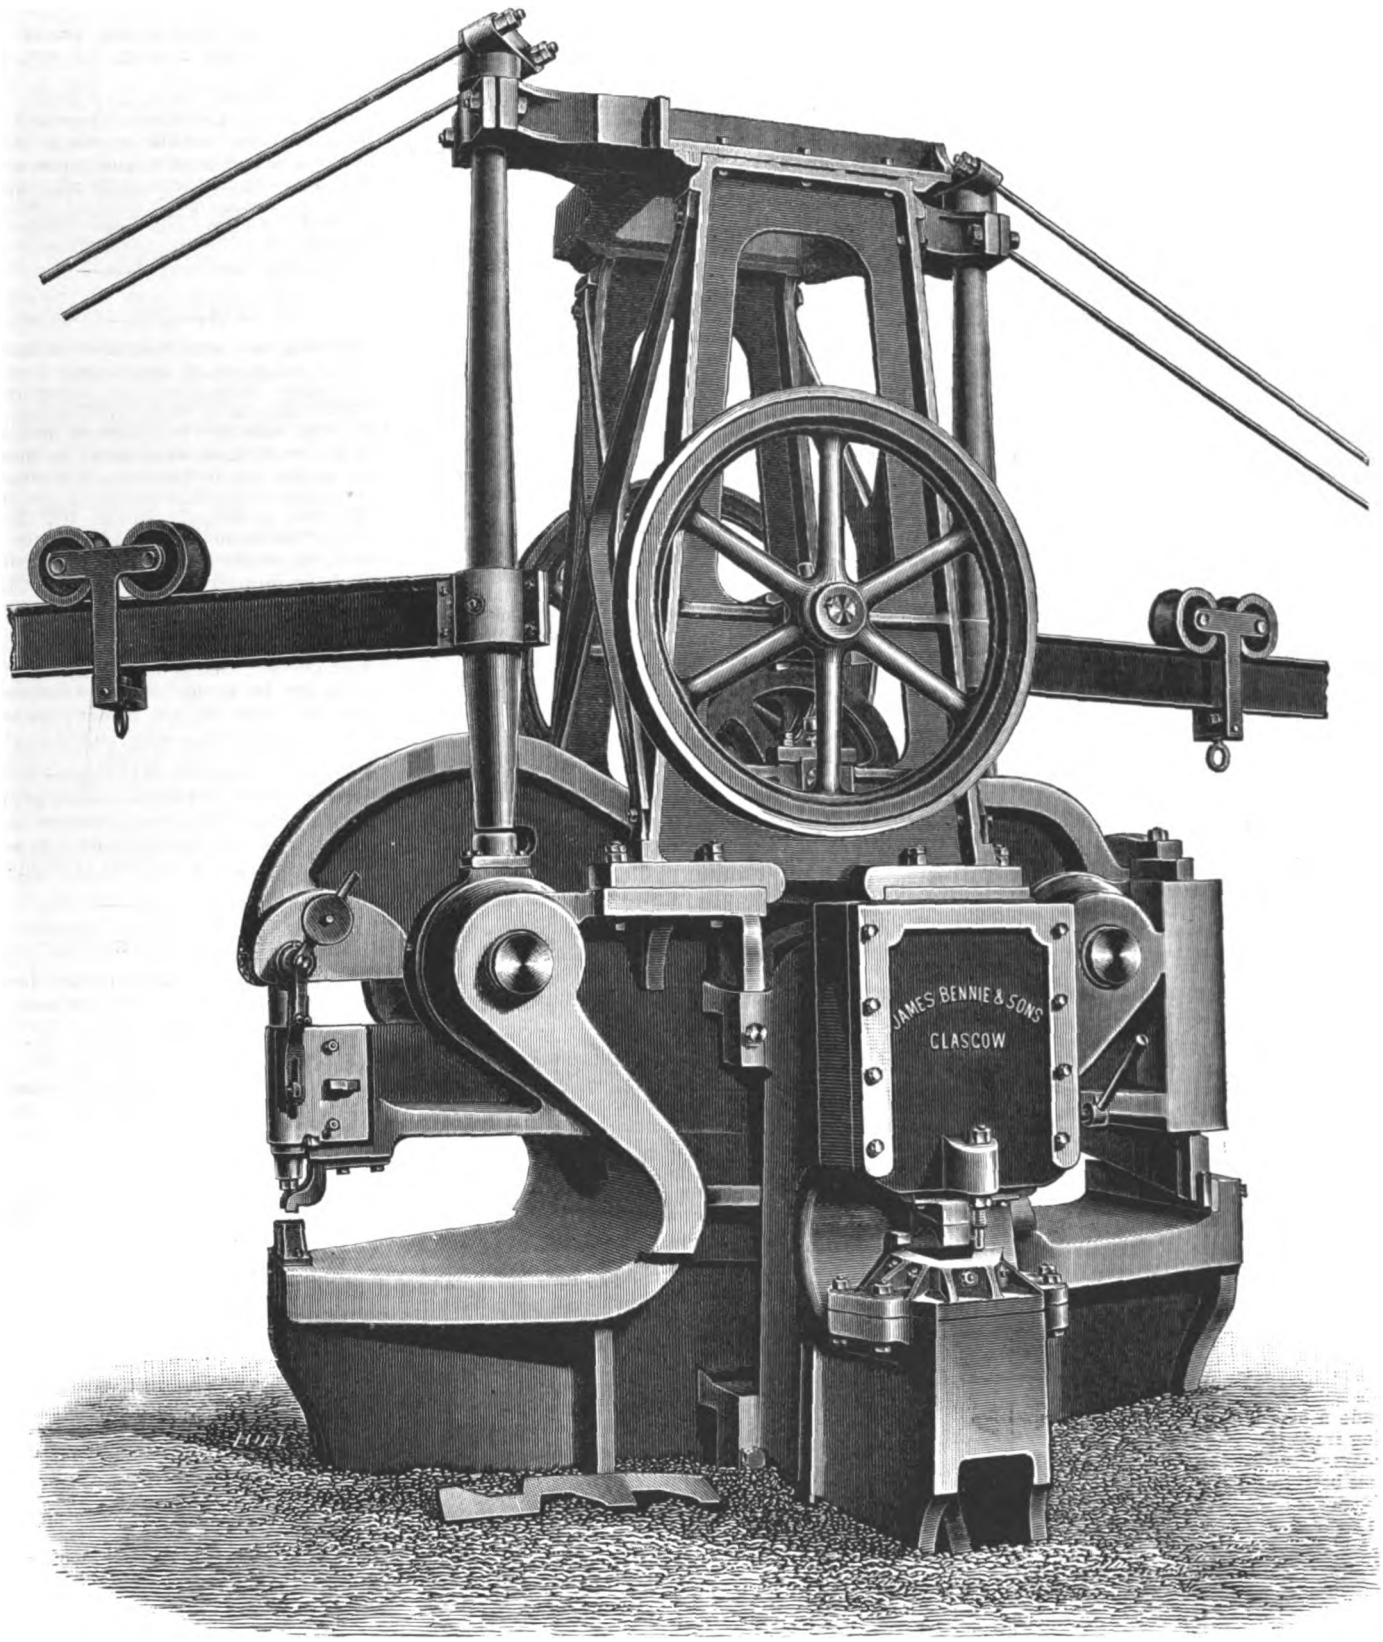
SHIPBUILDING AND MARINE ENGINEERING.—The steady increase in the cost of labour must tend to prevent additional orders being placed by shipowners. The members of the Amalgamated Society of Engineers on the Tyne and Wear, who asked for 2s. per week increased pay and one hour less work, have been offered 1s. increase to commence with the first pay in February. It is not yet known whether this counter-offer will be accepted. On Monday the drillers at Mr. John Dickinson's Palmer Hill Engine Works came out on strike because a delegate to the trade society had been dismissed, and so far no settlement is reported. A short strike also occurred at Messrs. S. P. Austin & Sons' Panns shipbuilding yard.

SHIPPING.—Outward freights have not improved, but are on the contrary somewhat easier, there being a large supply of tonnage and coal still being scarce. Some shipowners are in reality laying up some of their steamers for a week or two, and hope by not pushing for freights to assist a general improvement. Coal shipments here have not yet reached an average, due entirely to a short supply. There is evidently a growing feeling amongst the miners to obtain higher wages, 15 per cent. increase being demanded, but it is a very questionable policy. Homeward freights are not especially from the United States, so promising, a large amount of tonnage having been taken up.

NEWCASTLE, 22ND JANUARY, 1890.

THE IRON TRADE.—The iron works in the district continue to be busily employed, and prices are well maintained. A steady trade for some months to come is assured, as manufacturers, without exception, have booked forward orders. The blast furnaces at Low Walker, which were "damped down" some time ago, are about to be re-started by Messrs. Bell Brothers. A large quantity of fuel has been stored at the works during the past few weeks, and a cargo of Spanish ore is now being discharged at the jetty. It is understood that deliveries of ore will be continued without intermission till a large stock is accumulated, as the furnaces, when once re-started, are to be kept going so long as there is a demand for the product. Hematite iron is the article that is in future to be produced at these furnaces, and, so long as the steel trade holds good, the demand for that commodity is not likely to show any falling off.

ENGINEERS' WAGES.—In response to their demand for a wages advance of 2s. per week, from the 30th inst., the operative engineers have received from the employers an offer of 1s. per week. The men's decision with regard to the acceptance or refusal of this offer has not yet been made known. With reference to the claim of the same body for a reduction of the working hours from 54 to 53 per week, the employers say that under present circumstances they see no reason to make any alteration in the hours of work.



LABOURERS' WAGES.—The case of the shipyard and engine shop labourers, who have asked for a wages advance of 15 per cent., has been considered by the employers, with the result that they have refused the all-round advance asked for, but have at the same time intimated their willingness to revise existing rates, with a view to give an advance in certain cases. It is not yet definitely known what action the labourers will take with reference to this offer.

THE COAL TRADE.—A movement to demand another advance of 20 per cent. on wages rates is reported to have been commenced among the Northumberland miners. A largely attended meeting of coalowners was held at the Coal Trade Office, Newcastle, yesterday, to consider a claim from the Durham miners for a wages advance of 15 per cent. After a discussion with the miners' deputation which was in attendance, the owners informed the latter that they could not accede to the application. The shipments of coal and coke at Tyne dock for the week ending January 18th amounted to 110,461 tons, being a decrease of 9,359 tons as compared with the shipments for the corresponding week last year.

LARGE LEVER PUNCHING MACHINE.

CONSTRUCTED BY MESSRS. JAMES BENNIE & SONS, CLYDE ENGINE WORKS, GLASGOW.

LARGE LEVER PUNCHING MACHINE.

THE increase in the size of plates commonly used for shipbuilding has brought about the development of plant of corresponding size and power. In many shipbuilding and engineering establishments the pressure of work this winter has compelled many firms to spend considerable amounts of capital in heavy plant. Boiler-making tools of large size for manipulating the enormous plates that now enter into the construction of a modern marine boiler for engines of 4,000 h.p. and upwards have especially undergone recent development. The mere size of such machinery has brought about, as a necessary consequence, development in design, the main ideas being, of course, to secure great strength with simplicity of working parts. The large lever punching machine which we illustrate above has just been made by Messrs. James Bennie & Sons, Clyde Engine Works, Polmadie, Glasgow. The machine is capable of punching 1¼in. holes through a 1½in. plate. The gap on the punching end is 42in. deep, so that a hole can be punched in the centre of a plate 7ft. broad. A very broad shearing slide is also fitted, the blades of which are 3ft. long. A separate arrangement is fitted at the side for punching out at one stroke large square holes in stringer plates and also limber-holes or small man-holes. When placed in position the machine is sunk sufficiently to permit the punching to take place at a convenient level. Cranes are attached to the machine, for manipulating plates up to 2 tons in weight. A special high frame on the machine supports the cranes, and thus makes the whole plant quite self-contained. A considerable number of the leading shipbuilders have recently introduced punching and shearing machines of this size and design—for example, Messrs. Armstrong, Mitchell & Co., of Newcastle, and the Fairfield Shipbuilding Company, of Glasgow.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, Bedford Street, Strand, London, W.C.*

FRIDAY, 24TH JANUARY, 1890.

LARGE RAILWAY TRUCKS FOR MINERAL TRAFFIC.

THE question of the adoption of larger railway trucks for heavy goods traffic has again been brought into prominence, as one of the industrial problems of the day, by the meeting, held last week at Düsseldorf, of the Verein Deutscher Eisenhuttenleute, an association of German engineers and ironmasters similar to our Iron and Steel Institute. At the meeting a paper dealing with the subject exhaustively was read and discussed, with the result that the following resolution was passed unanimously, namely: "That this meeting is of opinion that it is desirable, in the interests of industry, commerce, and agriculture, to make the carrying capacity of railway waggons for heavy goods as large as possible, and in this opinion it recommends the Prussian State railway authorities to make a trial of 30-ton trucks without delay." It is scarcely possible to exaggerate the importance of this resolution. It is the formal expression of the opinion of a well-informed body of men, and it foreshadows immediate action in the direction indicated. The necessity for reducing the cost of transport makes itself felt more and more every year. The very life of manufacturing industries in some localities depends upon this necessity being promptly met. Competition has grown exceedingly keen, and will grow yet keener as Continental industry develops itself. How severely this competition is felt is significantly shown by some of the remarkable events of the last two or three years. Looking back over that period, we see large works transferred to the sea coast to escape the cost of land carriage, which, in the altered conditions of trade now prevailing, had become too burdensome. In other instances works have been carried beyond the seas and set up in foreign lands for like reason. Not less significant is the agitation, which is steadily growing, for the improvement and extension of the inland waterways. On the Continent, particularly in Germany, this movement has already made great progress, and it must be admitted that in this country considerable advances have been made in the same direction. The Congress, held some time ago in the Hall of our own Society of Arts, showed that the representatives of British industry are favourably disposed towards this solution of the problem, and are, moreover, resolved to work vigorously to obtain it. The question is, therefore, one of the deepest interest to the railway companies, whose future is largely bound up with it. In such circumstances it is not surprising to learn that certain of the most enterprising among them, notably the Midland, have begun to put to the test of experience the suggested reform in the design and construction of heavy goods trucks, and we may expect that the resolution arrived at last week in Germany will serve as a stimulant to further effort in the same direction. If our own companies delay, they will find themselves, instead of leading the way, compelled to follow in the wake of our foreign rivals in trade.

What is the nature of the progress made in the last twenty-five years? An exhibition of disused locomotives, if such exist, would show a constant increase in the weight and power of those engines. This augmentation of the tractive power on railways rendered it possible to add to the length of the trains, and accordingly we find in connection therewith a larger number of waggons coupled together. In this way power was economised and time saved. But the practicable limit has been reached in this direction. The longer the train, the greater is the friction on curves. Other disadvantages have made themselves seriously felt. The longer trains now run require more room at the stations, and a great extension of the sidings. Moreover, the work of shunting is rendered more difficult and long, and, as a consequence, the traffic is in a greater degree impeded. Another consequence of coupling together a large number of trucks is that the latter are subjected to rougher treatment in sorting and shunting, to stand which they have to be built of greater strength. But to obtain this additional strength their weight must be increased, so that the proportion of deadweight to carrying capacity, or paying load, undergoes augmentation. The ten-ton trucks now in use weigh from 5 to 7 tons. These, and some other considerations which might be mentioned, show that if economy of transport is to be found it must not be sought for in a further increase in the capacity of the trains. This is generally admitted by the railway authorities, and hence it is that we see them striving after improvement in the direction of greater truck capacity. The proposal is not altogether new. Some experience has already been gained to guide and support opinion in this matter. Twelve-and-a-half ton trucks, and even larger, are now running in an isolated way—that is, mixed up with others of smaller dimensions—over the lines of this country. In Germany a good many "12½-tonners" may be seen in the Breslau district, and in Luxemburg trucks of 15 tons for mineral traffic are common. With regard to the latter, Herr Schwabe, a high authority in this matter, estimates that by their use an annual saving of some 19,000,000 marks is effected. Everywhere the experience gained, in Europe as well as in the United States of America, confirms the opinion that the end proposed may be attained through a change of this character. We discussed several months ago some of the advantages of larger trucks; but we did not then go beyond a capacity of 15 tons. Now the project includes trucks of double that capacity. There may be some who deem it prudent to effect the change gradually, by first bringing into use the intermediate sizes. But we believe that all that can be said in favour of the 15-ton truck applies equally to that of 30 tons. Here again we have experience to fall back upon, both American and European; for, besides the common use of these larger trucks in the United States, we can point to some trials of a successful character now in progress on the Midland Railway in this country. As the result can hardly be doubtful, it seems desirable to take the whole step at once rather than to proceed tentatively. That such is the opinion of the members of the German technical association already mentioned is shown by the resolution at the meeting on the 12th inst.

Objections urged against the adoption of these heavy loads are that correspondingly heavy rails will have to be used, and that the wear and tear of the permanent way will be much increased. These objections are not founded on truth. Manifestly a truck body having a capacity of 30 tons will not be set upon two axles. The construction adopted will probably be that of the bogie-carriage, through which the weight will be better distributed over the rail. With such an arrangement the rail need not be more severely strained than now with the 10-ton

Digitized by Google

waggon. As for the wear and tear, there is no reason to believe that it would be greater with the heavier load when the latter is better distributed. It is not unreasonable to hope that it would be less. Anyhow, the loss incurred in this direction will be far from neutralising the gain. The wear and tear of the rolling stock will certainly be less, for we may safely assume that some improvements will be introduced into the design and construction of the new waggons. The barbarous system still in vogue of building trucks without spring buffers will surely not be continued. The violent and destructive thumpings to which our ears have grown accustomed will have no place in the new system. Besides, these bufferless trucks uselessly lengthen the train, as far as its carrying capacity goes, for they have to be loosely coupled together to enable them to get round the curves. Four inches between the trucks—that is, between the projecting ends of the side frames—is, for a train of fifty trucks, a clear loss of some seventeen feet, or, roughly, one truck's length in fifty. Probably the best system would be that of the central buffer. These are, however, matters which we do not intend to discuss now. For the present our object is merely to awaken an interest in the question which the action of our neighbours the Germans has made urgent.

THE AMERICAN NAVY PROPOSALS.

The news which has come from America regarding the proposal to increase the navy to a very large extent is a very curious commentary on the proceedings of the Pan-American Congress which has been engaged in sketching a constitution for both the American continents. This constitution would for ever render war impossible within its scope, and would make a composite dominion so strong and self-contained that no foreign enemy would ever dare to attack it. Arbitration and conciliation were to be the means in the future of settling all difficulties, and even before we have had a definite statement of the results of the Congress the world is startled by the most stupendous programme of warlike armament ever submitted by a constitutional Government. These proposals involve very great issues, economic, industrial, and political, and therefore should demand the closest attention of all whose opinions are likely to exercise any influence in the matter.

Mr. Secretary Tracey has submitted to the Naval Committee, after a consultation with the Shipbuilding Policy Board, in regard to the needs of the service, a report which recommends the construction of 92 vessels of different types and sizes. These will be built in fourteen years, and will cost, together with their maintenance during twenty-four years, 380,000,000 dollars. The scheme comprises 10 battle ships of 10,000 tons, 5,000,000 dollars each; 8 of 8,000 tons, 5,000,000 dollars each; 12 of 7,000 tons, 4,500,000 dollars each; 5 of 6,000 tons, 3,500,000 dollars each; 10 rams of 3,500 tons, 1,800,000 dollars each; 9 armoured cruisers of 6,250 tons, to make 19 knots an hour, 3,300,000 dollars each; 4 protected cruisers of 7,400 tons, to make 22 knots an hour, 3,500,000 dollars each; 2 protected cruisers of 4,000 tons, to make 19 knots an hour, 2,050,000 dollars each; 5 special cruisers of 1,200 tons, to make 18 knots, 500,000 dollars each; 15 torpedo cruisers of 900 tons, to make 22 knots an hour, 500,000 dollars each; and 3 artificers' ships, 2,000,000 dollars each. This programme is almost enough to take one's breath away, and those who have drawn it out have displayed a keen perception of the American character, which always goes in for something big, but which often sticks over trifles. The authors of the Report no doubt thought that they had discovered a solvent for some of the economic, industrial, and political problems which have for some time been puzzling American statesmen.

We have little hesitation in inferring that the huge surplus revenue with which the Americans have been blessed—or possibly cursed—for some years past is the direct cause of the programme. That surplus has been the despair of several administrations, and the difficulty increased as the National Debt was being paid off; but now a scheme has been brought forward which is meant to please all parties, by getting rid of the burden of the surplus, providing a large navy without incurring any extraordinary expenditure—in short, to prove that America is a great nation. The national vanity will be pleased, and it is just possible that in a fit of spread-eagleism—unless in the meantime common sense returns—the country may be involved in measures which will have immense consequences to the whole civilised world. The proposals have evidently been made for the purpose of perpetuating the present economic conditions of the country, and in the interests of monopolists who are becoming immensely rich as a consequence of the tariff which at present prevails, and they justify the fears of those who have always been opposed to the present fiscal system. It is a comparatively simple thing inaugurating a system of Protection, but it is very difficult to get rid of it. Everywhere vested interests are created, and these are able either directly or indirectly to bring sufficient influence to bear on the legislature. That they have done so most effectually in America is shown by the proposals we are considering, for if they are carried out they will commit the country to a policy of increased Protection for at least fourteen years. At the end of that time possibly the greater number of the ships will be of little use, so rapidly do things move at the present day, and then will again come the necessity for increased expenditure, not only for renewals, but also for the fixed charges which necessarily accompany the maintenance of a large fleet.

The policy involved in the programme will also have a powerful effect on the industrial future of America. In his message to Congress the President asked the legislators to consider the matter of the tariff with a view to reducing the receipts of the revenue as closely as possible to the wants of the Government, but he added that the changes should be made so as not to impair the just and reasonable protection of home industries. He made several proposals, which, however, did little but touch the fringe of the surplus. He moreover indicated that the Southerners should go in for iron-making and shipbuilding on a larger scale than they had hitherto attempted, and he stated that the protective system should be fairly applied even to the products of farms. This is quite logical, but it is practically impossible. Shipbuilding and engine-making can only be developed slowly, and we have no hesitation in saying that, if the proposed programme is carried out, the majority of the ships and engines will find their way to the scrap heap before many years. No doubt experience will be gained, but it will be at a terrible cost. The resources of the country are now sufficiently developed to allow shipbuilding, and the industries connected with it, to progress in a natural manner, and we trust that, before committing themselves to a policy which binds them to what may be a disastrous line of action, the people of America will carefully consider the question in all its bearings, and not allow themselves to be carried away by the proposals of politicians who are evidently influenced, either knowingly or unknowingly, by the monopolists, who are likely to enrich themselves at the expense of the country.

We might enlarge on the political aspects of the question, but that is outside of our sphere except so far as it affects industry and commerce. It must be quite evident, however, that if America becomes a warlike country, with a large navy and a powerful army, she is bound to depart from those peaceful ways to which so much of her prosperity is due.

ARBITRATION AMONG SCOTCH MINERS AND PAPERMAKERS.

The arbitration and conciliation movement is spreading rapidly. A few days ago Provost Black, of Airdrie, stated at a public meeting that he had recently attended a conference of delegates from the coalmasters and miners of the Airdrie and Slamannan districts, on which an understanding had been arrived at by which he was fain to believe that strikes among the miners would in future be prevented by an amicable arrangement between all the parties interested. It is stated that the basis of the arrangement is to the effect that each party shall have at least one fortnight's warning, and that in the event of the delegates being unable to adjust their differences the whole matter will be referred to arbitration. It is understood that the two last strikes had cost the district £100,000. We are glad to observe that the operative papermakers have fully appreciated the spirit of the masters' resolutions to which we recently alluded. At a meeting held a few days ago they unanimously expressed their gratitude to the employers for the manner in which they had met their request for a reduction of the weekly working hours. They further recommended, in order to overcome the difficulties attending common action on the part of the competing mills, that the Masters' Association be extended so as to include all the mill proprietors of the United Kingdom, and expressed the hope that a *modus vivendi* may be attained between a National Masters' Association and the National Union of Paper Mill Operatives. If this arrangement be carried out, it will be uncommonly like a trades guild; and if carried on, not only in the interests of the employers and the workmen, but also in that of the public, it would be another great step in the organisation of industry.

ELECTRIC LIGHT REGULATIONS.

The electric light seems doomed to be hampered by all sorts of vexatious restrictions, legal and not legal, but those proposed by the Board of Trade do not seem to be generally unnecessarily stringent, and may be welcomed as being likely to lessen the risks due to extreme negligence on the one hand, without hampering solid work on the other. There are, however, several points which need discussion, as it is not too late for any alterations to be made. The terms used are defined first. Low pressure supply is defined as 300 volts on a direct current, or 150 effective volts on an alternating. This seems somewhat hard on alternating currents. The subject may be looked at from several points of view, viz.: Danger to life from shocks from touching exposed fittings, danger to life from touching parts supposed to be insulated, and danger from fire caused by excessive leakage.

Danger to life from shocks from touching one exposed place needs another earth somewhere else in both cases, as the capacity of a consumer's alternating circuit is small if he has his own transformer. We do not know whether 300 volts direct is dangerous to life, by action on the muscles or otherwise; probably it is absurdly safe; but as a consumer would be connected with a large network of wires, there is much more likelihood of some other point being earthed, so that he gets a shock, than there is with the alternating secondary circuit. It is, therefore, much less likely that he will get a shock from the alternating current. If a consumer gets hold of two bare leads, the alternating current might certainly be more dangerous at the same pressure. This is the only point against the alternating current. As to fire, or danger from bad insulation, there is much more chance of the direct current breaking it down, as there is more chance of another leak elsewhere. A couple of leaks are much more likely to occur on a large system than a small one. We therefore think that, when fed from a transformer on the premises, the alternating current should at least be on the same terms as the direct. We may add that there seems to be nothing against a consumer transforming up again to anything he likes on his own premises. It is satisfactory to see the term "pressure" adopted instead of "electromotive force" or "tension."

A great deal of space is devoted to regulations as to safety. Rule 2, viz., "A high pressure supply shall not be delivered to the terminals on any consumer's premises except . . . .", is vague. The terminals should be more fully defined as the terminals connected to the consumer's wires.

The current in a given wire is limited by the rise of temperature. This is a much better way than by the current density. No wire is to rise 30° F. above the air, and any current density consistent with this may be used. In practice the current density is kept much below this to prevent excessive drop on the lamp terminals. This, like a good many other things commonly met with in rules and in specifications, might be left to the contractor. It would not pay to run hot leads. A check is, however, put on careless house wiring.

According to Rule 5, all high pressure conductors must be encased in iron pipe of at least ¼in. wall, earthed every 100 yards. This will press somewhat hardly on the use of bitumen culverts, and a ¼in. wall pipe seems scarcely necessary when a cable is already lead covered. A continuous metal casing, or a casing earthed at frequent intervals, may also give some trouble by electrical surgings with alternating currents. The protection which is given to underground mains against gasmen with picks or prodders is, of course, important; but for small leads we think a quarter of an inch too large a minimum thickness. Ordinary wrought iron gas pipe should be available. Where cast iron is used this thickness is, of course, advisable.

Rule 6 provides that no high pressure lead shall have an insulation of less than 50 megohms per mile. We trust the last expression may be altered into megohm miles. This degree of insulation seems too high to insist on just yet, as a contemporary has already pointed out. The question of insulation of a whole system of mains is difficult to discuss. If the object of such a rule is to guard against cables breaking down, the insulation demanded is very unnecessarily high. Here, again, it is best to leave the matter to the contractors or undertakers; it concerns only their pockets. To avoid bad places in a cable is another matter, but bad places soon get weeded out, and after that it does not matter what the insulation is. A general leakage of a fraction of an ampere from one set of leads to the other does not matter in the least. It is difficult to see how danger to life can come into the question at all. At most, all that is wanted is to prescribe a suitable automatic leak finder at the central station. The insulation in megohm miles even means little unless the pressure under which the measurement is taken is mentioned. Again, if the insulation of separate conductors is to be 50 megohm miles, the insu-

Digitized by Google

lation of the inner conductor of a concentric main should be 100 megohm miles.

Rule 7 provides that where concentric conductors are not used there shall not be an earth leakage of more than ·04 ampere direct or ·02 ampere alternating. This would be a most unnecessary and vexatious rule. In an alternating system of any size the capacity current would be more than ·02 ampere. The rule does not say whether the leakage current is measured with the other side artificially earthed or not. As we have already said, the general leakage through the earth does not really matter to anybody. Of course, it might affect telephones or telegraphs if very excessive, but unless there is a fault, and a really local earth current, which it is, of course, to the undertaker's interest to avoid, this is unlikely. As to danger to life, if by earth current is meant, as we suppose, the current measured between one side and an artificial earth, a man putting himself in place of the galvanometer would get through him ·04 ampere or less according to the pressure. Taking a man's resistance as 1,000 ohms, this would be no worse than touching both poles of a 40 volt circuit. If his resistance were more than 1,000 ohms he would only get a minute burn, as the resistance of the body is mostly at the surface. The alternating ·02 would thus correspond to 20 volts held with a good contact. Apart from this, there seems no chance of a man's getting a shock from underground wires. It would therefore seem a great pity to enforce Rule 7.

Rule 8 provides against sparks between the insulating coverings of oppositely charged conductors. It is difficult to conceive how such sparks could possibly be produced. We have often heard accounts of curious sparks produced by alternating currents, but they have never borne investigation. We have been told, however, on the best authority, that these sparks do occur.

Rule 14 provides that sub-stations "must be established on suitable premises in the sole occupation of the undertakers." This would preclude the central station people from renting a basement only; they must occupy the whole of the premises. This is probably a slip. The rule also assumes an attendant at each sub-station, which seems quite unnecessary, at least in the case of transformers.

Rule 16 provides that all high pressure conductors, fuses, switches, and the transformer itself must be enclosed in metal casing, at least a quarter of an inch thick, connected to the earth. This would be a very expensive regulation to follow. The leads would not be considered efficiently protected by ordinary wrought iron gas piping, and special cast pipes would have to be used The only use the metal casing could be would be to confine the smoke if some turns of the primary or secondary were short-circuited and were burning out. Any non-inflammable case would do this, as once a coil or two begins to heat the neighbouring insulations will char, so that the fault spreads till the fuse goes. We think it would be perfectly safe to specify a fireproof case. Some may prefer to build a brick recess or little cellar, or to use a stoneware case. We do not know if open circuit transformers will ever come into use, but they could not well be put in cases of ¼in. metal. There seems to be no need for these restrictions when the transformer is out of doors, but still on the consumer's premises. It may be very much to the point, however, to insist on some sort of conducting screen efficiently earthed, to avoid any chance of shocks.

There are two omissions in the rules as to consumers' premises. Nothing is said about the insulation between the primary and secondary or between the primary and earth in the transformer, except the rule as to the leakage current of ·02 amperes; and, though there is a provision that there shall be means to prevent the secondary being dangerously charged, there is nothing said about safety appliances to prevent an accidental earth on one or other of the secondary leads.

It is provided that if the undertaker suspects a fault on a consumer's premises, he may inspect, and if there is a fault, he may cut off the supply. This is very important. Direct supply companies will do this in their own interests. There is nothing to make the company do so, however, when house transformers are used, as an earth then does not matter to them, and they have no means of knowing there is a ground on their system till an accident happens. The undertaker has the right of cutting off the supply if the resistance of the leak is under 5,000 ohms.

The second division refers to regulations as to supply, and seems to be very much what is wanted. Low pressure supply may vary three per cent. each way, which is somewhat excessive, and high pressure two per cent. It is as well to be lenient to the undertakers, at least at first. Two per cent. each way on high pressure circuits is more serious, as losses in the transformers have to be added to that. It is, however, to the interests of the supply companies to keep uniform pressure, so it is very advisable not to lay down strict rules on the subject. It is not as if electric lighting had some monopoly.

On the whole, as we have already said, the rules may be considered well drawn up and to the point. They are, however, too severe as to safety. Electric lighting ought to be quite safe, and we would like to see rules whose enforcement would make it a great deal safer than gas; but the industry has already been so throttled and tied down that it is a pity to stifle it any more by any unnecessary or exaggerated precautions. A gas supply is more dangerous than an electric, but we are not obliged to put the meter in a fireproof chamber, or to take correspondingly elaborate precautions against fires, poisoning, and explosion. Any one can fix a swinging bracket so that the flame can be left playing against a wooden partition. There are no automatic arrangements specified for cutting off the supply if an unlighted jet is left on, or for indicating a leak in a main. Of course when electric light is as familiar as gas, all these regulations will be swept away as unnecessary, but gas was not hampered by them at the outset. On the other hand, regulations which will make accidents from electric light wires practically impossible are much wanted, and if the Board of Trade rules err on the side of strictness, it is easy to make them more workable and still abundantly safe.

INTERNATIONAL JOULE MEMORIAL.

The Council of the Royal Society have appointed a committee to set on foot a memorial to the late James Prescott Joule, and they have resolved to raise a fund for establishing a memorial of an international character commemorative of the life work of Joule, which shall have for its object the encouragement of research in physical science. We are glad that the Royal Society have taken these steps for honouring the work of our illustrious countryman, and, although this work has been done in England, we feel sure that it is right to establish the memorial on an international basis. There has been, in the history of science, no research which has had more important results on the industrial community, and it is highly proper that those who appreciate the value of the labours of their fellow-men in furthering progress should contribute to a fund which has for its object the commemoration of the discoverer of the universal law of the Conservation of Energy. Not only is the scientific and industrial value of Dr. Joule's work felt by the engineer, manufacturer, and the worker in applied science, but the economist and philanthropist and politician will all admit that material benefits have already flowed from his discoveries by promoting economy in all the principal industries of mankind. It is by the work of masters like Joule that the world can realise the worth of the scientific progress of the age, and by contributions to the Joule Memorial Fund testify to the appreciation of the improved conditions under which man now labours and lives.

Sir Henry E. Roscoe has volunteered his services as honorary secretary to the fund, and will be willing to receive donations addressed to the International Joule Memorial, Royal Society, Burlington House, London, W.

Letters to the Editor.

STEAM BOILER LEGISLATION.

To the Editor of "Industries."

Sir,—The thanks of the whole boiler insurance world at least, to say nothing of that perhaps not insignificant crowd of persons who unfortunately own boilers, are due to you for your exceedingly able and temperate leader, referring to a dangerous and misleading article, entitled "Boiler Explosions and the Board of Trade," which appeared in your contemporary *Engineering* of the 3rd inst.

Many of its readers would recognise the arguments of Mr. Lavington E. Fletcher, manager of the Steam Users' Insurance Association of Manchester, in the said article, and feel sure that the author of it, whoever he may be, was simply pouring out the treasures of that gentleman's mind. They would also feel that the dignity and fairmindedness of your contemporary was at stake in allowing an *ex parte* statement, of so malignant and false a character, to be published in its columns without that correction and revision which everything that appears as an editorial should command.

Sir William Fairbairn, Mr. Hugh Mason, M.P., and Mr. Lavington E. Fletcher have for the last nineteen years held themselves to have the entire right of road on the subject of boiler inspection, and, since the Steam Users' Association became a boiler insurance company, on that of boiler insurance also. When they went for boiler inspection only, no other company had sufficient inspectors, and, to injure their then competitors, Sir W. Fairbairn, then president of the Steam Users' Association, did not flinch from stating, before the Select Committee on Boiler Explosions, in 1870, that "In fact, judging from the number of efficient inspectors employed by the first and largest insurance company in Manchester, where more than 10,000 boilers are enrolled, the number of inspectors is probably in the ratio of one to about 1,000 boilers. We have about 2,000 boilers and seven inspectors. I think the insurance company which was the first that was formed has upwards of 10,000 boilers, and it is a question with me whether they have any more inspectors than we have for the 2,000 boilers. From this it will be noticed that thorough inspection is out of the question." Now, the truth is, that at that time the Steam Users' Association had five or six regular inspectors, and one or two occasional inspectors, all of whom resided in Manchester, whereas the Boiler Insurance and Steam Power Company, Limited (the company referred to), had twenty-seven regular inspectors and two occasional ones, resident in different centres, such as London, Edinburgh, Glasgow, Manchester, Birmingham, Bristol, Dundee, Belfast, &c., so as to save time and travelling expenses.

Although Sir William Fairbairn's attention was drawn to the falsity of his statements, he never corrected or withdrew them, and they have formed the nucleus of many a pithy sentence in the Steam Users' Association notes, and published in the daily papers of the last nineteen years. In fact, this huge, gratuitous, and mischievous falsehood is the base of nearly all assertions that are so glibly made by those who know nothing of the pains and labour taken by the engineers of boiler insurance companies to thoroughly do the work they undertake.

In the article in your contemporary, to which I have already alluded, it is said: "We have previously pointed out in these columns that it is cheaper for insurance companies to take the risk of a few explosions than to faithfully inspect every boiler enrolled on their books." This has been the parrot cry of all the officials, travelling agents, and employés of the Steam Users' Association since 1870, with the honourable exception of the late Mr. Peacock, whose sense of truth and fairmindedness would not allow him to be the mere ignorant mouthpiece and tool of any man.

What has been the experience of the Mutual Boiler Insurance Company, the English and Scottish Boiler Insurance, and the Newcastle Boiler Insurance Company? Has it paid them to neglect inspection? Will it pay any remaining struggling company left in the field?

In face of the result of the last formal investigation at Newcastle upon the explosion on board the s.s. "Perseverance," how long will it take to put the company involved into difficulties? It will either have to give such inspection as the oldest and wealthiest companies, and charge at least double its present rates, or it must collapse. These formal investigations, which are now being put in force—largely, I believe, through the influence of your valuable journal—will so open the eyes of the public that they will soon discover the reliable boiler insurance companies, and will also be able to gauge the spurious philanthropy of those who are always forcing Governmental harass and worry upon them in the shape of compulsory inspection of steam boilers by the Board of Trade. At that investigation the Scottish Boiler Insurance and Inspection Company, Limited, declared, both through their manager, Mr. J. D. Young, and through their counsel, Mr. Henderson, "that they undertook no duty to the insured, no duty as to the superintendence of these boilers. . . . The mere fact of their sending in these reports, as I have stated, does not mean that they undertake to relieve the owners of the duty of looking after his boilers. These inspections are made primarily for the safety of the insurance company itself, but, having made this inspection, they are quite willing, so far as in their power, to afford the owner any information which may be of use to him in keeping the boiler in a safe condition."

When the boiler inspector turns out to have been originally a "jobbing blacksmith" the owner will have to be thankful for small mercies in regard to advice and inspection. This was the opinion of the Court, as shown by the following judgment: "But we do think, in the interests of human life, and as a safeguard against insurances effected by immoral or careless owners, that they (the Scottish Boiler Insurance Company) should in future, if they can, by a thorough inspection, satisfy themselves that the boiler they are going to insure is as safe as it can be."

Comment on such a judgment is superfluous, and it behoves the smaller insurance companies to put themselves on a proper footing with regard both to the quality of their inspectors and their inspections, or the reason for their existence will have passed away.

Yours, &c.,

Boiler Inspector.

Manchester, January 20th, 1890.

THE MARKING OF GOODS.

To the Editor of "Industries."

Sir,—The Trade Marks Act has been of benefit to the manufacturers in England, and it would seem advisable to have it adopted elsewhere. I see from your recent Copenhagen letter that a local brewery exports "Bavarian beer" to Brazil. The same sort of thing exists in various other industries—Belfast hams are imported to that town from Denmark, and Aberdeen granite is largely derived from the Baltic. It must be just as well in the long run if the origin of every product were candidly acknowledged. If the things are good in themselves, it does not much matter to the user whether they are derived from Turkey, Toronto, or Timbuctoo.

Yours, &c.,

A. Rose.

London, 20th January, 1890.

THE CHILIAN GOVERNMENT AND IMPORT DUTIES.

To the Editor of "Industries."

Sir,—It will no doubt interest manufacturers and others to know that the Chilian Government, being desirous to encourage mining, agriculture, and other industries, has decreed that from the 1st of January, 1890, the following manufactures shall be admitted free from import duties into the Republic:—

(1.) All machinery and tools for the use of agriculture, mining, trades, and industries.

(2.) Pipes and tubes of composition, copper, iron (galvanised or ungalvanised), elbows, joints, tees, and other materials connected with these.

(3.) Iron or steel wire (galvanised or ungalvanised) up to No. 14 inclusive, and also copper, for the transmission of electricity.

(4.) Instruments for telegraphs and telephones, iron or steel posts, and other utensils for the permanent way of steam, horse,

Digitized by Google

or portable railways; also wheels, axles, and hoops for railways, and cars for portable railways.

(5.) Iron in sheets.

Having resided on the west coast of South America for twenty-three years, I shall be happy to give any further information in my power to any of your readers.

Yours, &c.,
J. Harris.

Devonshire Road, Forest Hill, London, S.E.,

BLEICHERT'S WIRE ROPE TRAMWAYS.

To the Editor of "Industries."

Sir,—I should be obliged if any of your readers could give me some particulars through the medium of your journal as to the practical success in working of Bleichert's patent system of wire rope tramways; also as to where the plant can be obtained in this country.

Yours, &c.,
Inquirer.

London, 21st January, 1890.

THE SUN AND PLANET MOTION.

To the Editor of "Industries."

Sir,—In the report in the daily press of the "James Watt Anniversary Dinner," held on Saturday last in the Grand Hotel, Glasgow, the Chairman, Mr. Ebenezer Kemp, is represented as having said: "But for James Watt's invention of the separate condenser, the sun and planet motion," &c. In crediting the inventive genius of Watt with the sun and planet motion, Mr. Kemp is giving expression to the not always discriminating popular belief in such matters. The sun and planet motion was amongst the earliest inventions of William Murdoch, who was frequently spoken of by Sir William Fairbairn as "the most distinguished veteran of mechanical engineering;" while James Nasmyth, in his "Autobiography," refers to the "vast series of workshops of that celebrated establishment [the Soho Works], and to the special machine tools, which, I believe, were chiefly to be ascribed to the admirable inventive power and common-sense genius of William Murdoch."

Watt, in his patent, dated 25th October, 1781, had five distinct methods of obtaining the circular motion. The fifth in the specification was the sun and planet motion of William Murdoch, and was the method finally adopted in the Soho machinery in preference to the four devised by Watt. It is thus referred to in a letter by Boulton:—"Mr. Watt's packet is not ready. I am to wait till his drawings [of the rotary motion] are completed, which he is executing himself. There was some informality in those sent from Soho. Besides, he has another rotative scheme which I could have told him of long ago, when first invented by William Murdoch, but I did not think it a matter of much consequence." Further, Dr. Smiles, on the authority of Mr. Joseph Parkes himself, relates in his "Lives of Boulton and Watt":—"At an interview which Mr. Parkes had with Mr. Watt at Heathfield, at which Murdoch was present, Murdoch spoke of the sun and planet motion as his invention, which Watt did not contradict."

The sun and planet motion is not the only invention of William Murdoch's erroneously attributed to James Watt.

Yours, &c.,
Alex. Murdoch.

January 20th, 1890.

THE WATT ANNIVERSARY AT GREENOCK.

The Watt Anniversary Lecture, under the auspices of Greenock Philosophical Society, was delivered on the 17th inst. by Mr. James Riley, general manager to the Steel Company of Scotland. The subject was "Steel: Its Manufacture, Properties, and Uses." Mr. Riley spoke of the various constituents of steel, and the methods employed in the production of steel in ancient and modern times. Afterwards he went on to speak of the Siemens process, and we quote from this part of his lecture in full as follows:—

Suppose for our present purpose we fully examine the materials charged into a Siemens furnace when working a charge by the Siemens (or scrap and ore) process, the steel to be of ordinary ship quality. Usually the charge consists of 75 per cent. pig iron and 25 per cent. of good scrap steel. As I want to impress you with the amount of precision and care which the steel maker must exercise, I will give you the weights of the elements which go to make up one ton of the pig iron used and one ton of the steel produced:—

	Hematite Iron. Cwt.	Qrs.	Lb.	Oz.		Mild Steel. Cwt.	Qrs.	Lb.	Oz.
Iron	18	2	21	8	...	19	3	9	9
Carbon	0	2	17	15	...	0	0	4	1
Silicon	0	1	19	8	...		trace.		
Sulphur.....	0	0	0	14	...	0	0	1	1
Phosphorus ...	0	0	0	14	...	0	0	1	1
Manganese ...	0	0	22	7	...	0	0	11	3
Copper	0	0	0	14	...	0	0	1	1

All the steel made in this country for engineering or constructive purposes is required to pass certain definite tests of strength and ductility. For instance, steel for shipbuilding, when tested for tensile strength, must break when subjected to a load of not less than 27 or more than 31 tons per square inch, and previous to rupture there must be an elongation of not less than 20 per cent. on 8in. of length of the tested piece—in other words, the tested piece of steel which measures 8in. in length must measure not less than 9⅗in. before it breaks under the pulling stress applied to it. Now variations in any of the elements which are in combination with the iron have a distinct influence on the behaviour of the steel under test, as well as in other respects, and I think you will be somewhat astonished at the effects produced by small variations in composition. For instance, Siemens steel of the composition I have given would probably satisfy the tests named, but if the amount of carbon present were increased by only two parts in ten thousand, it would probably require a greater load than 31 tons to break it, and might not stretch the required 20 per cent. on 8in., and would be liable to rejection by the surveyor. Now, these two parts in ten thousand mean by actual weight less than half a pound of carbon to the ton of steel. Seeing, then, that the influence of carbon is so great, you will readily understand that it demands careful attention when making the steel, and that it is to the contents of this element the steel maker principally looks to enable him to furnish metal of any desired tensional strength; thus, carbon steel—as I may term it—reaches its greatest tensile strength when it contains about 1 per cent. of carbon; it then has an elastic limit of about 30 tons with an ultimate tensile strength of about 60 tons on the square inch of sectional area; it will then, however, have but little ductility, and will be comparatively brittle. In working our charge, we can, if we exercise due care, control the amount of carbon, silicon, and manganese in the steel, but we cannot remove the sulphur and copper, and only by special means the phosphorus. Now, as all these elements are more or less objectionable, it is better to take care that they are not present in the materials we put into the furnace; hence the importance of the preliminary analysis of materials, which is strictly performed in all well-managed works. Proceeding, the lecturer described the method of charging the furnace, and referred to the invention of Mr. Henderson, of Glasgow, regarding the method of producing ferro-manganese, by which the manufacture of mild steel became possible.

And now I should like to speak of one of the most important inventions of recent times, one which has had great and far-reaching effects on the iron and steel trades of this country and of the Continent—I mean what is known as the "basic process" for the production of steel. As you probably know, much the larger portion of the ores of iron found in Great Britain contain phosphorus, and the iron made from them is unfit for the manufacture of steel by the ordinary Bessemer or Siemens process. For many reasons, therefore, it was important that a method should be discovered by which such pig iron could be so treated as to produce good, useful steel. Many of the most eminent metallurgists gave their attention to it, and at length, after many partial successes, this was fully accomplished by what is known as the Thomas-Gilchrist or basic process. The basic process has been useful to the world in general, but as yet has been sadly disadvantageous to Great Britain. To my mind, this is in part due to the distrust which has attended the use of basic steel in this country, a distrust which will not easily be removed from the basic-Bessemer process, but for which there is no ground in connection with the open-hearth basic process. The whole of the operations in the basic-Bessemer process are of such a character as to render it peculiarly easy to produce metal which shall not be thoroughly homogeneous and of a perfectly reliable character. I know, and frankly admit, that by the exercise of the greatest skill and care this can be avoided and thoroughly good steel be produced, and I am glad to state that evidence of the truth of this remark has been furnished in the steel sent out from works in the West of Scotland, yet none the less do I assert that only in the open-hearth furnace can the basic process be conducted with such uniformity, regularity, certainty, and comparative ease as will warrant that firm confidence in results which has been developed with regard to acid steel of high quality.

A great deal has been said and written of late of the advantages to be derived from the use of aluminium in the manufacture of steel; but so far as my experience goes—and I must say that is now of considerable extent—I think this usefulness is considerably overrated. It is true that the use of aluminium in the molten steel greatly increases its fluidity and reduces its melting point, and thus enables one to make castings which shall be sound, and which, being cast at a lower temperature, shall be less subject to the hot cracks due to contraction. But then equally good results can be, and are, obtained without its use, as I have demonstrated to more than one of its advocates. Further, our experience leads us to the conclusion that the strength and ductility of steel are not improved by additions of aluminium, even if they are not slightly impaired. Thus, then, as this metal is as yet a very costly one (although daily becoming less so), it is only in a tentative, careful manner that I would use it. Chromium has been largely made use of as an alloy with steel, particularly for purposes of war, as, for instance, in shot and shell, armour-plates, &c. Like aluminium it is somewhat expensive to use, its first cost being considerable, and the loss by oxidation being great. Considerable care and skill are required in the production of chrome steel to get the necessary amount of chromium present, together with a reasonable amount of carbon. The effects of chromium in steel are shown in increased hardness and strength, with some loss in ductility, in increased facility for hardening and tempering in water or oil, and also in great difficulty in machining. In working this steel at the hammer or rolls care must be taken that the masses of steel are heated very gradually, and not to a very high temperature.

But to my mind the most important of these alloys, and the one which is likely to prove of greatest interest, because of its probable great utility, is that which has been termed ferro-nickel or nickel-steel. Nickel can be allowed with iron or steel to any extent. No serious difficulties are met with in doing this; no special plant is required, the ordinary means for producing steel being ample in this case. Most remarkable properties are possessed by this steel, properties which vary to a very large extent, according to the contents of nickel. When present to the extent of not more than, say, 7 per cent., the effects are a great augmentation of the hardness and tensile strength, a very considerable raising of the elastic limit, and much less corrodibility. Think for a moment of the immense revolution which has been made in engineering and shipbuilding—especially the former—by the command of steel of the latter description. By its means you have been able to accomplish the very great developments which have been achieved during the past dozen years. You have been able to make boilers which will stand pressures previously utterly out of reach. In nickel steel you have the means placed in your hands of nearly doubling your pressures without increasing the weight or dimensions of your boilers. The possibilities which are here presented to the engineer I leave you to imagine; but perhaps I ought to say before leaving this matter that already the probability of the introduction of nickel steel into the industrial arts has developed considerable excitement amongst the owners of mining property where nickel is found, and I anticipate that in no long time the supplies of this metal will be so much increased that it will be possible to supply the steel at prices which will not be considered at all unreasonable.

TESTING THE FORTH BRIDGE.

On the 21st inst. the Forth Bridge was preliminarily tested. Two trains, each consisting of three engines and fifty waggons laden with coal, and weighing 1,800 tons, steamed slowly across the bridge from the South Queensferry end. The two trains, each of which was 1,000ft. in length, moved slowly along, periodically stopping to enable the engineers to examine the levels and deflections. The trains proceeded as far as the middle of the north cantilever, and then returned slowly to the south end. The following is the official report:—"Sir John Fowler and Mr. Baker, engineers of the Forth Bridge, have to-day tested the two 1,700ft. spans by placing on the centres two trains, each made up of fifty loaded coal waggons and three of the heaviest engines and tenders, the total load thus massed upon the spans being the enormous weight of 1,800 tons, which is more than double what the bridge will ever be called upon in practice to sustain. The observed deflections were in exact accordance with the calculations of the engineers, and the bridge exhibited exceptional stiffness in all directions."

The test by the engineers was preparatory to the passing of the first engine over the structure to-day, with Mr. Thompson, chairman of the company, and Lord Colville; and every part of the bridge will be in order for the visit of his Royal Highness the Prince of Wales on the 4th of March. It may be interesting to mention that during the heavy gale of Sunday, when the wind gauges on Inch Garvie recorded a pressure of 37lb. per square foot, the maximum lateral movement of the centre cantilever was less than 1in.

The Deptford Electric Light Station.—We have heard many reports about the Deptford Station, but they are generally not sufficiently authenticated for publication. We have recently been informed on good authority that the telephones are disturbed to a serious extent, the disturbance being sensible even at Paris when "put through." It is rumoured that the railway companies may prevent the use of the mains along their viaducts owing to the disturbance. The action on the telephone circuits was mentioned at the Board of Trade inquiry, but no measures were then taken as to the matter.

INSTITUTION OF ELECTRICAL ENGINEERS.

CONTINUATION OF PRESIDENTIAL ADDRESS.

(*Concluded from page 67.*)

In speaking of the properties of bodies which, like manganese steel, are slightly magnetic, it may be well here to enter a caution. But little that is instructive is to be learned by testing filings, or the like, with magnets, as these show but little difference between bodies which are slightly magnetic and those which are strongly magnetic. Suppose the filings to be spheres, in the following table are given comparative values of the forces they would experience in terms of μ, if placed in a magnetic field of given value, μ having its ordinary signification—that is, being the ratio of the kick on the galvanometer when a ring is made of the material of the filing to the kick if the ring is made of a perfectly non-magnetic material:—

μ.	Attraction.	
1	0	
1·47	0·18	Non-magnetic body.
3·6	1·2	Manganese steel with 12 per cent.
5	1·5	Manganese steel with 9 per cent.
10	2·1	
100	2·8	
1,000	2·98	

Now bodies in which μ is so small as 3·6 belong distinctly to the non-magnetic class; but the test with the magnet would very markedly distinguish them from manganese steel with 12 per cent. of manganese. The distinction, however, between $\mu = 3·6$ and $\mu = 1,000$ is comparatively small; whereas under the conditions of experiment, μ is much more than 1,000 for most bodies of which iron is the principal constituent.

The effect of stress on the magnetic properties of iron and nickel have been studied by Sir W. Thomson. A fact interesting from a broad and general point of view is that the effects of stress are different in kind in the case of iron and nickel. In the case of iron, for small magnetising forces in the direction of the tension, tension increases the magnetisation; for large forces, diminishes it. In the case of nickel the effect is always to diminish the magnetisation.

When one considers that the magnetic property is peculiar to three substances—that it is easily destroyed by the admixture of some foreign body, as magnanese—one would naturally expect that its existence would depend also on the temperature of the body. This is found to be the case. It has long been known that iron remains magnetic to a red heat, and that then it somewhat suddenly ceases to be magnetic, and remains at a higher temperature non-magnetic. It has long been known that the same thing happens with cobalt, the temperature of change, however, being higher; and with nickel, the temperature being lower. The magnetic characteristics of iron at a high temperature are interesting. Let us return to our ring, and let us suppose that the coils are insulated with a refractory material, such as asbestos paper, and that the ring is made of the best soft iron. We are now in a position to heat the ring to a high temperature, and to experiment upon it at high temperatures in exactly the same way as before. The temperature can be approximately determined by the resistance of one of the copper coils. Suppose, first, that the current in the primary circuit which we use for magnetising the ring is small; that from time to time, as the ring is heated and the temperature rises, an experiment is made by reversing the current in the primary circuit and observing the deflection of the galvanometer needle. At the ordinary temperature of the air the deflection is comparatively small; as the temperature increases the deflection also increases, but slowly at first: when the temperature, however, reaches something like 600° C., the galvanometer deflection begins very rapidly to increase, until, with a temperature of 770° C., it attains a value of no less than 11,000 times as great as the deflection would be if the ring had been made of glass or copper, and the same exciting current had been used. Of course a direct comparison of 11,000 to 1 cannot be made: to make it we must introduce resistance into the secondary circuit when the iron is used; and we must, in fact, make use of larger currents when copper is used. However, the ratio of the induction in the case of iron to that in the case of copper, at 770° C., for small forces is no less than 11,000 to 1. Now mark what happens. The temperature rises another 15° C.; the deflection of the needle suddenly drops to a value which we must regard as infinitesimal in comparison to that which it had at a temperature of 770° C.; in fact, at the higher temperature of 785° C. the deflection of the galvanometer with iron is to that with copper in a ratio not exceeding that of 1·14 to 1. Here, then, we have a most remarkable fact: at a temperature of 770° C. the magnetisation of iron 11,000 times as great as that of a non-magnetic substance; at a temperature of 785° C. iron is practically non-magnetic. These changes are shown in Fig. 8. Suppose now that the current in the primary circuit which serves to magnetise the iron had been great instead of very small. In this case we find a very different order of phenomena. As the temperature rises the deflection on the galvanometer diminishes very slowly till a high temperature is attained; then the rate of decrease is accelerated until, as the temperature at which the sudden change occurred for small forces is reached, the rate of diminution becomes very rapid indeed, until, finally, the magnetism of the iron disappears at the same time as for small forces. Instead of following the magnetisation with constant forces for varying temperatures, we may trace the curve of magnetisation for varying forces with any temperature we please. Such curves are given in Figs. 9 and 10. In the one diagram, for the purpose of bringing out different points in the curve, the scale of abscissæ is 20 times as great as in the other. You will observe that the effect of rise of temperature is to diminish the maximum magnetisation of which the body is capable, slowly at first, and rapidly at the end. It is also very greatly to diminish the coercive force, and to increase the facility with which the body is magnetised. To give an idea of the magnetising forces in question, the force for Fig. 8 was 0·3; and as you see from Figs. 9 and 10, the force ranges as high as 60. Now the earth's force in these latitudes is 0·43, and the horizontal component of the earth's force is 0·18. In the field of a dynamo machine the force is often more than 7,000. In addition to the general characteristics of the curve of magnetisation, a very interesting, and, as I take it, a very important, fact comes out. I have already stated that if the ring be submitted to a great current in one direction, which current is afterwards gradually reduced to zero, the ring is not in its non-magnetic condition, but that it is, in fact, strongly magnetised. Suppose now we heat the ring, whilst under the influence of a strong magnetising current, beyond the critical temperature at which it ceases to have any magnetic properties, and that then we reduce the current to zero, we may in this state try any experiment we please. Reversing

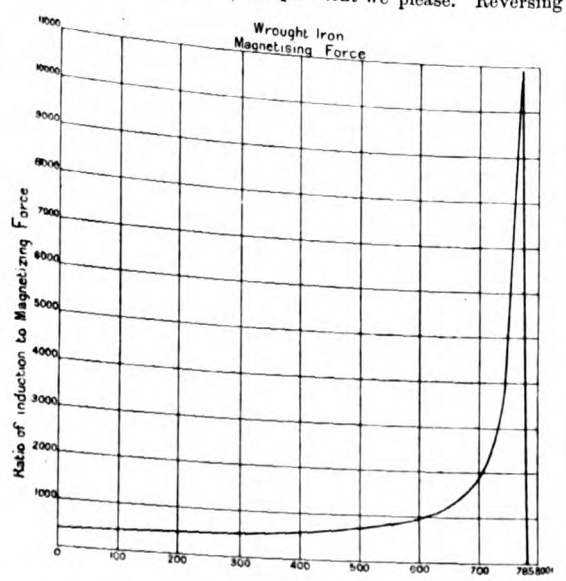

FIG. 8.

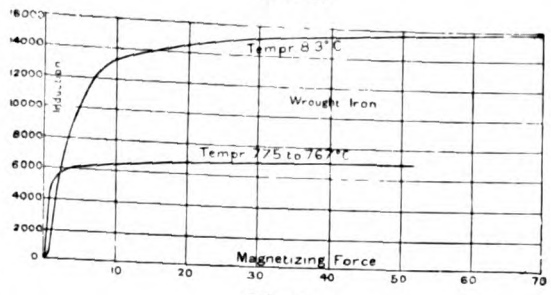

FIG. 9.

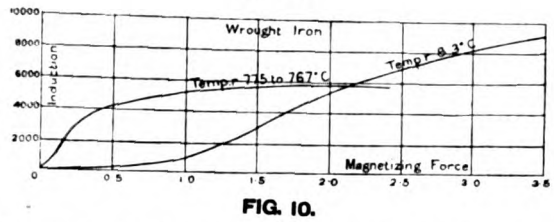

FIG. 10.

the current on the ring, we shall find that it is in all cases non-magnetic. Suppose next that we allow the ring to cool without any current in the primary, when cold we find that the ring is magnetised; in fact, it has a distinct recollection of what had been done to it before it was heated to the temperatvre at which it ceased to be magnetic. When steel is tried in the same way with varying temperatures, a similar sequence of phenomena is observed; but for small forces the permeability rises to a lower maximum, and its rise is less rapid. The critical temperature at which magnetism disappears changes rapidly with the composition of the steel. For very soft charcoal iron wire the critical temperature is as high as 880° C.; for hard Whitworth steel it is 690° C.

The properties of an alloy of manganese and iron are curious. More curious are those of an alloy of nickel and iron. The alloy of nickel and iron containing 25 per cent of nickel is non-magnetic as it is sure to come from the manufacturer; that is to say, a substance compounded of two magnetic bodies is non-magnetic. Cool it, however, a little below freezing, and its properties change: it becomes very decidedly magnetic. This

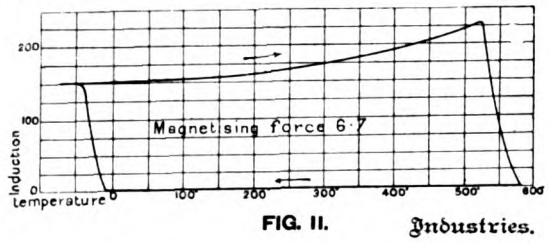

FIG. 11. Industries.

is perhaps not so very remarkable; the nickel steel has a low critical temperature—lower than we have observed in any other magnetisable body. But if now the cooled material be allowed to return to the ordinary temperature it is magnetic; if it be heated it is still magnetic, and remains magnetic till a temperature of 580° C. is attained, when it very rapidly becomes non-magnetic, exactly as other magnetic bodies do when they pass their critical temperature. Now cool the alloy: it is non-magnetic, and remains non-magnetic till the temperature has fallen to below freezing. The history of the material is shown in Fig. 11, from which it will be seen that from −20° C. to 580° C. this alloy may exist in either of two states, both quite stable—a magnetic and a non-magnetic—and that the state is determined by whether the alloy has been cooled to −20° C. or heated to 580° C.

Sudden changes occur in other properties of iron at this very critical temperature at which its magnetism disappears. For example, take its eletrical resistance. On the curve Fig. 12 is shown the electrical resistance of iron at various temperatures, and also the electrical resistance of copper or other pure metal. Observe the difference. If the iron is heated, its resistance increases with an accelerating velocity, until, when near the critical temperature, the rate of increase is five times as much as the copper; at the critical temperature the rate suddenly changes, and it assumes a value which, as far as experiments have gone, cannot be said to differ very materially from a pure metal. The resistance of manganese steel shows no such change; its temperature coefficient constantly has the value of ·0012, which it has at the ordinary temperature of the air. The electrical resistance of nickel varies with temperature in an exactly similar manner. Again, Professor Tait has shown that the thermo-electric properties of iron are very anomalous—that there is a sudden change at or about the temperature at which the metal becomes non-magnetic, and that before this temperature is reached the variations of thermo-electric property are quite different from a non-magnetic metal.

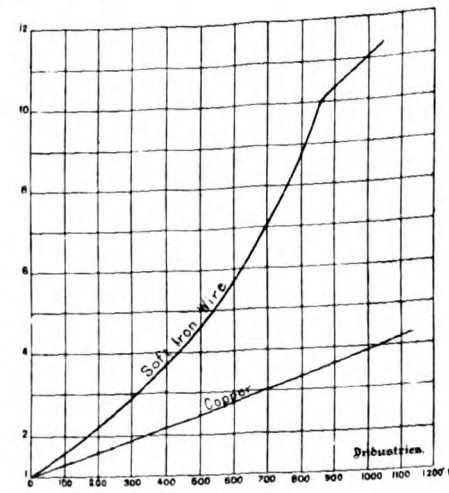

FIG. 12.

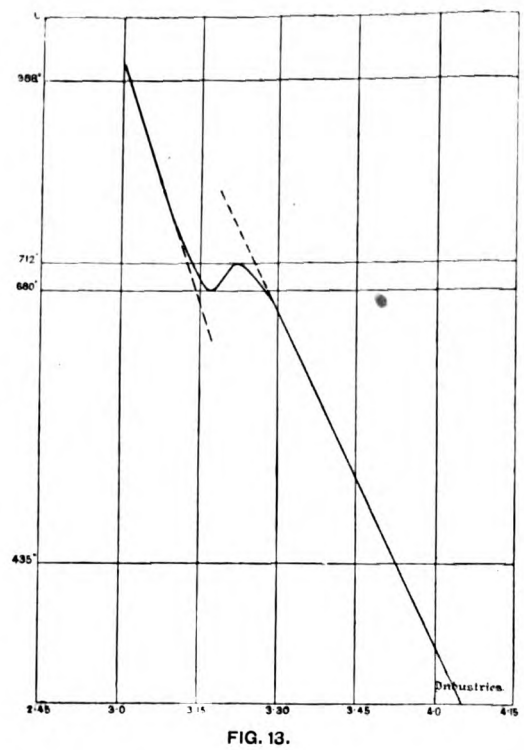

FIG. 13.

Professor Tomlinson has investigated how many other properties of iron depend upon the temperature. But the most significant phenomenon is that indicated by the property of recalesence. Professor Barrett, of Dublin, observed that if a wire of hard steel is heated to a very bright redness, and is then allowed to cool, the wire will cool down till it hardly emits any light at all, and that then it suddenly glows out quite bright again, and afterwards finally cools. This phenomenon is observed with great difficulty in the case of soft iron, and is not observed at all in the case of manganese steel. A fairly approximate numerical measurement may be made in this way: Take a block of iron or steel on which a groove is cut, and in this groove wind a coil of copper wire insulated with asbestos; cover the coil with many layers of asbestos; and finally cover the whole lump of iron or steel with asbestos again. We have now a body which will heat and cool comparatively slowly, and which will lose its heat at a rate very approximately proportional to the difference of temperature between it and the surrounding air. Heat the block to a bright redness, and take it out of the fire and observe the resistance of the copper coil as the temperature falls, due to the cooling of the block. Plot a curve in which the abscissæ are the times, and the ordinates the logarithms, of the increase of resistance of the copper coil above its resistance at the temperature of the room. If the specific heat of the iron were constant, this curve would be a straight line; if at any particular temperature latent heat were liberated, the curve would be hori-

zontal so long as the heat was being liberated. If now a block be made of manganese steel, it is found that the curve is very nearly a straight line, showing that there is no liberation of latent heat at any temperature. If it is made of nickel steel with 25 per cent. of nickel, in its non-magnetic state, the result is the same—no sign of liberation of heat. If now the block be made of hard steel, the temperature diminishes at first; then the curve (Fig. 13) which represents the temperature bends round: the temperature actually rises many degrees whilst the body is losing heat. The liberation of heat being completed, the curve finally descends as a straight line. From inspection of this curve, it is apparent why hard steel exhibits a sudden accession of brightness as it yields up its heat. In the case of soft iron the temperature does not actually rise as the body loses heat, but the curve remains horizontal, or nearly horizontal, for a considerable time. This, again, shows why, although a considerable amount of heat is liberated at a temperature corresponding to the horizontal part of the curve, no marked recalescence can be obtained. From curves such as these it is easy to calculate the amount of heat which becomes latent. As the iron passes the critical point it is found to be about 200 times as much heat as is required to raise the temperature of the iron one degree centigrade. From this we get a very good idea of the importance of the phenomenon. When ice is melted and becomes water, the heat absorbed is eighty times the heat required to raise the temperature of the water one degree centigrade, and 160 times the heat required to raise the temperature of the ice by the same amount. The temperature of recalescence has been abundantly identified with the critical temperature of magnetism.* I am not aware that anything corresponding with recalescence has been observed in the case of nickel. Experiments have been tried, and gave a negative result, but the sample was impure; and the result may, I think, be distrusted as an indication of what it would be in the case of pure nickel. The most probable explanation in the case of iron, at all events, appears to be that when iron passes from the magnetic to the non-magnetic state it experiences a change of state of comparable importance with the change from the solid to the liquid state, and that a large quantity of heat is absorbed in the change. There is, then, no need to suppose chemical change; the great physical fact accompanying the absorption of heat is the disappearance of the capacity for magnetisation.

What explanations have been offered of the phenomena of magnetism? That the explanation must be molecular was early apparent. Poisson's hypothesis was that each molecule of a magnet contained two magnetic fluids, which were separated from each other under the influence of magnetic force. His theory explained the fact of magnetism induced by proximity to magnets, but beyond this it could not go. It gave no hint that there was a limit to the magnetisation of iron—a point of saturation; none of hysteresis; no hint of any connection between the magnetism of iron and any other property of the substance; no hint why magnetism disappears at a high temperature. It does, however, give more than a hint that the permeability of iron could not exceed a limit much less than its actual value, and that it should be constant for the material, and independent of the force applied. Poisson gave his theory a beautiful mathematical development, still useful in magnetism and in electrostatics.

Weber's theory is a very distinct advance on Poisson's. He supposed that each molecule of iron was a magnet with axes arranged at random in the body; that under the influence of magnetising force the axes of the little magnets were directed to parallelism in a greater degree as the force was greater. Weber's theory thoroughly explains the limiting value of magnetisation, since nothing more can be done than to direct all the molecular axes in the same direction. As modified by Maxwell, or with some similar modification, it gives an account of hysteresis, and of the general form of the ascending curve of magnetisation. It is also very convenient for stating some of the facts. For example, what we know regarding the effect of temperature may be expressed by saying that the magnetic moment of the molecule diminishes as the temperature rises, hence that the limiting moment of a magnet will also diminish; but that the facility with which the molecules follow the magnetising force is also increased, hence the great increase of μ for small forces, and its almost instantaneous extinction as the temperature rises. Again, in terms of Weber's theory, we can state that rise of temperature enough to render iron non-magnetic will not clear it of residual magnetism. The axes of the molecules are brought to parallelism by the force which is impressed before and during the time that the magnetic property is disappearing; they remain parallel when the force ceases, though, being now non-magnetic, their effect is nil. When, the temperature falling, they become again magnetic, the effect of the direction of their axes is apparent. But Weber's theory does not touch the root of the matter by connecting the magnetic property with any other property of iron, nor does it give any hint as to why the moment of the molecule disappears so rapidly at a certain temperature.

Ampère's theory may be said to be a development of Weber's: it purports to state in what the magnetism of the molecule consists. Associated with each molecule is a closed electric current in a circuit of no resistance; each such molecule, with its current, constitutes Weber's magnetic molecule, and all that it can do they can do. But the great merit of the theory—and a very great one it is—is that it brings magnetism in as a branch of electricity; it explains why a current makes a magnetisable body magnetic. It also gives, as extended by Weber, an explanation of diamagnetism. It, however, gives no hint of connecting the magnetic properties of iron with any other property. Another difficulty is this: When iron ceases to be magnetisable, we must assume that the molecular currents cease. These currents represent energy. We should therefore expect that, when iron ceased to be magnetic by rise of temperature, heat would be liberated; the reverse is the fact.

So far as I know, nothing that has ever been proposed even attempts to explain the fundamental anomaly, Why do iron, nickel, and cobalt possess a property which we have found nowhere else in nature? It may be that at lower temperatures other metals would be magnetic, but of this we have at present no indication. It may be that, as has been found to be the case with the permanent gases, we only require a greater degree of cold to extend the rule to cover the exception. For the present, the magnetic properties of iron, nickel, and cobalt stand as exceptional as a breach of that continuity which we are in the habit of regarding as a well-proved law of nature.

After the delivery of this address, Sir William Thomson said the President had done well to emphasize the marvellous properties of iron, nickel, and cobalt, but he thought these properties were not quite so much isolated as would appear from the address. Faraday showed the continuity between paramagnetic and diamagnetic bodies, and that all substances are susceptible to magnetism when subjected to sufficiently intense magnetising forces. He had also compared the relative susceptibilities of materials such as glass, bismuth, wood, &c.; but the absolute determination of their susceptibilities still presents a large field for interesting and valuable research The fact that the magnetic properties of such substances could be compared was itself of immence importance, whilst Tyndall's observations on the properties of bread, Iceland spar, &c., which can be made, or are naturally magnetically anisotropic, further enhances the interest connected with the subject. As regards the President's remark that Poisson's theory gave no hint of hysteresis, this he thought was open to question, for the theory refers to coercive force, and this is hysteresis under another name. Coming to the subject of recalescence, Sir William said this was of immense importance, and one of the wonders duly accentuated by the President. In this connection he wished to add that most of the work on the latent heat of iron, about the temperature at which the recalescence occurs, had been done by the President himself. The region about the ripple in Fig. 13 requires further investigation, and, if possible, a cycle such as Andrews used in his experiments on evaporation and condensation should be devised. The material exists in two or more different states at the same temperature, and if the effect is reversible then the iron should cool whilst heat is being supplied to it. In conclusion, Sir William suggested that several physical properties of the material should be tested statically whilst it was kept at temperatures little above and little below the critical one, and also during the various states in which the material exists at the same temperature.

Professor Ewing, in commenting on the enormous amount of hysteresis exhibited by the alloy of nickel and iron (Fig. 11), said he had looked for hysteresis in similar alloys and found none; now he saw why he found none, for his experiments were made between ordinary atmospheric temperatures and 212° F., whilst Dr. Hopkinson, by increasing the range of temperature, had passed the critical points and shown the hysteresis to be very great. In his own (Professor Ewing's) experiments on iron, he found that by tapping a rod whilst subjected to magnetising force, a permeability of 20,000 could be obtained.

The discussion was continued last evening.

* I have only recently become acquainted with the admirable work of M. Osmond on recalescence. He has examined a great variety of samples of steel, and determined the temperatures at which they give off an exceptional amount of heat. Some of his results are apparent on my own curves, though I had assumed them to be mere errors of observation. For example, referring to my Royal Society paper, there is, in Fig. 38, a hint of a second small anomalous point a little below the larger one. And, comparing Figs. 38 and 38A, we see that the higher the heating, the lower is the point of recalescence; both features are brought out by M. Osmond. The double recalescence observed by M. Osmond in steel with a moderate quantity of carbon I would explain provisionally by supposing this steel to be a mixture of two kinds which have different critical temperatures. Although M. Osmond's method is admirable for determining the temperature of recalescence, and whether it is a single point or multiple, it is not adapted to determine the quantity of heat liberated, as the small sample used is enclosed in a tube of considerable mass, which cools down at the same time as the sample experimented upon.

GRAPHIC CONSTRUCTIONS FOR DYNAMOS AND MOTORS.

By Professor Robert H. Smith.

II.

(*Continued from page* 43.)

When the magnet-winding is compound or shunt the following very simple graphic method may be used to obtain the various characteristics of dynamos and motors from the fundamental curve co-ordinating the whole e.m.f. and the magnet ampere-turns. It will be found convenient to suppose this curve reduced in horizontal scale so that its horizontal ordinate will represent a current of such magnitude that if it acted in the shunt coils it alone would give the whole actual ampere-turns. This current will be called the "equivalent shunt current."

The above table gives the nomenclature that will be used in explaining the constructions.

The whole ampere-turns are $(\alpha\tau + A\,t)$ in the case of the series coils being inside the shunt terminals. The curve co-ordinating this with E the whole e.m.f. generated in the armature is reduced horizontally by dividing every horizontal ordinate by τ, the number of turns in the shunt coils; so that the horizontal ordinates become $\left(\alpha + A\frac{t}{\tau}\right) = \alpha^1$, and the curve will be called the E/α^1 curve. When the shunt is between the brushes the E/α^1 curve has its horizontal ordinates equal to $\left(\alpha + a\frac{t}{\tau}\right)$.

The former case is shown for a generator in Figs. 5, 6, and 7 on the next page. A straight line is drawn through the origin at the slope ρ. For each possible shunt current α this line gives the corresponding value of ϵ, the e.m.f. between the shunt terminals.

Now, suppose two actually corresponding or simultaneous values of E and ϵ taken. Take the point on the $E\,\alpha^1$ curve at height E, and the point on the ρ line at height ϵ; and join these points. The slope of this line is $R\frac{\tau}{t}$, because the difference of heights is $(E - \epsilon) = AR$, and the difference of horizontal distance is $(\alpha^1 - \alpha) = \left(\alpha + A\frac{t}{\tau}\right) - \alpha = A\frac{t}{\tau}$, and $\frac{AR}{A\frac{t}{\tau}} = R\frac{\tau}{t}$.

This slope is constant for all values of E, ϵ, and A. Therefore any number of pairs of corresponding values of E and ϵ can at once be found by drawing a number of parallel lines at this slope between the ρ line and the E/α^1

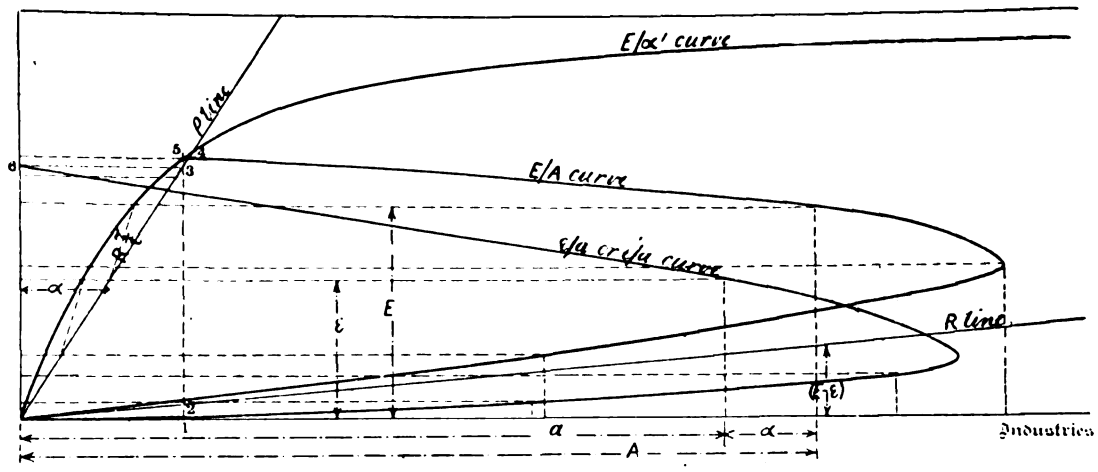

FIG. 7.

ference of height of the ends of each such value of $(E - \epsilon)$ and E/α' curve) gives the corresponding value of A, this difference of height is to be taken with the dividers. The straight line $R = (E - \epsilon)/A$ having been drawn, the point on it having this height $(E - \epsilon)$ is found by help of the dividers set as above, and the horizontal distance of this point is the corresponding value of A. A vertical being drawn through the E point on the E/a' curve, the intersection gives the corresponding point of the E/A curve—i.e., the "internal characteristic." From this point is set backwards towards the left hand the simultaneous value of a, taken by the dividers from the ϵ point on the ρ line. This gives the value of $a = A - \alpha$, and a vertical being drawn downwards to the horizontal drawn at the level ϵ, the intersection gives the simultaneous point of the "external characteristic" ϵ/a or e/a. Any desired number of points of the two characteristics can be found very quickly in this manner.

The "shunt generator" is merely a particular case of this construction. In it $t = 0$, and therefore $R\frac{\tau}{t} = \infty$; that is, the lines at this slope are to be drawn *vertical*. Fig. 6 shows the construction, which requires no further explanation, because it is identical with that of Fig. 5, except in the above particular.

The "shunt" machine is the one limit of the range of applicability of this construction. At the other limit we have the "series" machine. For this the construction is, of course, not required; but it may be well to point out that it would fail at this limit, because the ρ line becomes vertical, and the $R\frac{\tau}{t}$ line becomes horizontal; the value of $(E - \epsilon)$ becomes continually zero—in fact, there exist no shunt terminals between which to take ϵ.

It may also be noted that the initial slope of the E/α' curve must be steeper than the ρ line, because this line must intersect this curve in order that the construction should be possible. The meaning of this is that a compound wound generator will not begin to work until a certain limit of speed is passed, the initial slope of the E/α' curve being proportional to the speed.

It is important to distinguish between the two cases in which (1) slope $R\frac{\tau}{t} < \rho$ (see Fig. 5), and (2) $R\frac{\tau}{t} > \rho$ (see Fig. 7).

The limit of case (2) is the shunt machine, Fig. 6. Referring to Fig. 7 it will be seen that if $R\frac{\tau}{t}$ be greater than the initial slope of the E/α' curve, then for $\epsilon = 0$ we have also $E = 0$. But if $R\frac{\tau}{t}$ be less than this initial slope, we obtain a finite minimum value of E when $\epsilon = 0$, this corresponding to short-circuiting with zero external resistance betweens the terminals, the magnets then being excited by the series coils only. In either case, so long as $R\frac{\tau}{t} > \rho$, the value of $(E - \epsilon)$, and, therefore, also the value of A, reaches a maximum where the $R\frac{\tau}{t}$ line cuts the E/α' curve at a point where this curve is parallel to the ρ line. The maximum value of a, the external current, is reached at somewhat lower values of E and ϵ. Passing upwards from the position of maximum A, the value of $(E - \epsilon)$ continually decreases until that limiting position of the $R\frac{\tau}{t}$ line is reached which makes the difference of level of its intersections on the ρ line and the E/α' curve, that is, makes $(E - \epsilon)$ correspond on the R line to a horizontal distance A equal to a, the horizontal distance of the lower intersection (on the ρ line). This position is marked on Fig. 7 by the points 1, 2, 3, 4, where 1, 2, 3 are on the same vertical line, 3, 4 is at inclination $R\frac{\tau}{t}$, and 12 equals the difference of level between 3 and 4. Point 5 on the vertical 1, 3, and on same level as 4, is the final point of the E/A curve, and point 6 in the vertical axis, and on same level as 3, is the final point of the ϵ/a or e/a curve. Note that in this case these final values of E and ϵ are both *below* the crossing of the E/α' curve and the ρ line.

In the shunt machine Fig. 6, point 5 coincides with point 4.

If the $R\frac{\tau}{t}$ be a less slope than that of the line joining the origin with the touching point of the tangent of the E/α' curve parallel to the ρ line, then the values of $(E - \epsilon)$ and of A decrease from the very beginning; that is, both the curves E/A and ϵ/a, starting far to the right hand, run continuously towards the left hand. The ϵ/a curve starts from the horizontal axis.

If $R\frac{\tau}{t}$ be little more than ρ, then the value of E changes very little, while ϵ increases from 0 up to its maximum value, and while A and a increase to their greatest and again decrease to their final values.

The smaller the internal resistance R is made, it is clear from the construction that the greater becomes the range of A and a for given small variations of E and ϵ. With this kind of machine there is no other way of keeping ϵ fairly constant under large variations of a.

Turning now to the case in which $R\frac{\tau}{t} < \rho$, we find that this must be again divided into two sub-cases: (a) wherein $R\frac{\tau}{t}$ is greater than the slope of the E/α' curve, where it crosses the ρ line; and (b) wherein $R\frac{\tau}{t}$ is less than this slope.

The value of E and the slope of the E/α' curve at this crossing with the ρ line are among the most important quantities as regards the working of dynamos, whether generator or motor. Therefore the special names E_k and k will be used to indicate them. Note that E_k increases and k decreases as the speed of rotation increases, E_k in a greater ratio than the speed. If the curve followed Fröhlich's formula, the value of k would be in simple inverse proportion to the speed, and the value of E_k would be a constant multiple of the speed minus a constant amount.

If $k < R\frac{\tau}{t} < \rho$ (see Fig. 5), then E reaches a maximum limit when $\epsilon = 0$. From this limit as ϵ increases E and $(E - \epsilon)$, and consequently A and a continually decrease. The other limit is reached as in the previous case, when the difference of level between the ends of the $R\frac{\tau}{t}$ line gives a value of A upon the R line equal to the value of a obtained from the ρ line. In Fig. 5 this limiting position is indicated by the points 1, 2, 3, 4, 5, 6, the ends of the E/A and ϵ/a curves being 5 and 6. In this case, the final value of ϵ is less than E_k, as in Fig. 7, but the final value, and indeed all values, of E are greater than E_k.

(To be continued.)

THE PHYSICAL SOCIETY.

At a meeting of this Society on the 17th inst., Dr. S. P. Thompson made a communication "On Electric Splashes," and illustrated his subject by beautiful experiments on the production of Lichtenberg's figures. The author has recently investigated these phenomena as modified by varying the conditions under which the figures are obtained, and has arrived at the following conclusions. First, the nature of the dielectric plate does not change the character of the figures produced; and secondly, the nature of the powders used seems to have no material effect on their shape. In the course of his experiments he has found a mixture of sublimed sulphur and lycopodium to give better figures than the red lead and sulphur usually employed, and also that a large and highly polished knob is advantageous, particularly when the Leyden jar is charged negatively. Sometimes when obtaining negative figures, nebulous patches occur, and these were attributed to the so-called electric winds sent off from roughnesses on the knob when not sufficiently well polished. If instead of bringing the knob in contact with the plate, it is only brought near to it, then a peculiar figure closely resembling a "splash" results. A positive splash consists of short lines radiating from the point of approach, whilst a negative splash is made up of more or less rounded spots which become elongated in a radial direction as their distance from the centre of the splash increases. Negative splashes are, however, much more difficult to produce than positive ones. When viewed in the dark, the discharge producing the splash is seen to consist of a bundle of small sparks which branch outwards on approaching the plate. In conclusion, the author remarked that roughnesses on a conductor produce more electric wind when the conductor is charged negatively than when positively charged, and he invited the opinions of members as to the causes of the differences observed between positive and negative electricity.

A paper "On Galvanometers," by Professor W. E. Ayrton, F.R.S., T. Mather, and W. E. Sumpner, D.Sc., was read by Professor Ayrton. In fitting up the physical laboratories of the Central Institution of the City and Guilds of London Institute, the authors have had occasion to obtain galvanometers of various types and patterns, some of which have been made to special designs, and specimens of instruments embodying recent improvements were exhibited at the meeting. The question as to whether fairly sensitive galvanometers should be astatic or non-astatic was answered in favour of the former system, from the fact of its being less affected by external magnetic disturbances, and the greater ease with which great sensibility may be obtained. The usual method of placing the mirror inside the coil was shown to be undesirable, and in the newer forms of instruments Mudford's improvement of placing the mirror outside the coils has been adopted, the space near the axis of the coil being nearly filled with wire. It was also shown that if wire be wound in a certain approximately spheroidal space near the magnets, then these convolutions will tend to oppose the more distant portions of the coil; however, by winding the two parts in opposite directions they conspire to deflect the magnet. Details as to methods of supporting the coils were then discussed, and the importance of fitting them in boxes mounted on hinges or otherwise, so as to be readily removable, was pointed out. A galvanometer devised for teaching purposes, and provided with variable damping arrangements, was described, in which the damping is effected by enclosing the mirror in a glass cell, whose sides can be caused to approach or recede by turning a milled head outside the instrument. This arrangement enables the damping to be varied between wide limits, and its effect on the swing produced by a given discharge can be determined. The instrument is also serviceable both as an ordinary damped galvanometer, or as a fairly ballistic one. In measuring quantities of electricity by the first swing of a galvanometer needle, a correction has usually to be introduced for damping; this correcting factor is simple enough when the damping is small, but becomes more complicated as the damping increases, and to facilitate the calculations a table of values of the factor for various values of λ (the logarithmic decrement) has been calculated. From this it appears that for values of λ less than 0·5 the value of the factor is very nearly $(1 + \frac{1}{2}\lambda)$, the correction usually employed. Improvements in methods of insulating the coils and terminals of galvanometers required for insulation tests were next described, the principle of which may be gathered from Figs. 107 and 108 in Professor Ayrton's "Practical Electricity." A special form of instrument for high insulation work was exhibited, in which the copper resistance of the coils is nearly 400,000 ohms, and the shortest path along which surface leakage can take place from the coils to the base of the instrument is between 30in. and 40in. of ebonite artificially dried by sulphuric acid. This is attained by supporting the coils from two corrugated ebonite rods which depend from a brass ring carried on the top of three corrugated pillars fixed to the base plate. The instrument was constructed to the drawings and specification by Messrs. Nalder Bros., but the method of supporting the coils was suggested by Messrs. Eidsforth & Mudford. With reference to the proportionality of deflection to current in reflecting galvanometers, it was pointed out that ordinary instruments may differ as much as 2 per cent. within the limits of the scale, hence showing the necessity for calibration when any approach to accuracy is desired. Galvanometers of the D'Arsonval type sometimes differ from proportionality quite as much as the one above referred to, but by fitting such instruments with curved pole pieces, and allowing the coil to hang freely from the top suspension, a proportionality true to less than 0·15 per cent. has been attained over a scale about 30in. long. Coming to the question of sensitiveness, the importance of keeping the wire as close as possible to the magnets was brought prominently forward, as well as the necessity of reducing the "figures of merit" of various instruments to the same standard in comparing their sensibilities. The standard adopted as most convenient and closely approximating to practical usage is arrived at by supposing the distance of the mirror from the scale to be equal to 2,000 scale divisions, and the sensibilities for current and quantity are given as *scale divisions per micro-ampere* and *scale divisions per micro-coulomb* respectively. The period of oscillation is also taken into account. A table showing the resistances, sensibilities, coefficients of self-induction, and volumes of the coils of various instruments, together with the relations existing between them, accompanies the paper, and from this it appears that in the best astatic double-coil instruments of from 10,000 to 30,000 ohms resistance the number of scale divisions per microampere may reach 400 times the resistance to the $\frac{2}{3}$th power ($400\ R^{\frac{2}{3}}$), when the period is ten seconds. In obtaining data of various instruments the authors have consulted, among others, Professor Threlfall's paper on "The Measurement of High Specific Resistances," in the *Phil. Mag.* for December, 1889, and noticed two serious errors. The first of these makes an instrument constructed according to Messrs. Gray's pattern nine times less sensitive than it actually was, whilst the sensibility of a form recommended in the paper is given seventeen times too great.

On account of the lateness of the hour, the discussion was adjourned till the 6th prox.

Notes.

ELECTRICAL ACCIDENTS IN NEW YORK.

The *Standard* and *Daily News* are keeping up the supply of electrical accidents in the United States. Their latest report is about a damp horse smelling a damp lamp-post, and is not so impossible as usual. In the interests of electrical progress in Great Britain, it would be well to allow a technical man to see these telegrams before they are published, for no one knows how much damage may be done to a cause by the spreading broadcast of a number of reports apparently prejudicial to its interests.

INSTITUTE OF MARINE ENGINEERS.

A meeting of the Institute of Marine Engineers was held on the 13th inst., when a paper on "The Marine Engine Considered as a Machine" was read by Mr. J. Hawthorn. The meeting was specially for junior engineers and graduates. Mr. Hawthorn began by pointing out the importance of mathematics to the engineer who wished to understand the leading principles underlying the structural arrangement of the engine, as well as those involved in proportioning the strengths of the various parts. The conversion of the motion of the piston and piston rod into that of the crank shaft, being the primary object, was referred to first, and the power exerted by the piston when impelled by the force of the steam was considered, and the losses due to resistance and friction consequent upon the change of motion from reciprocating to rotary were pointed out. The guides and guide shoes, the crossheads and connecting-rod motions, and the several and appointed duties of these details were referred to and discussed, as well as the forces at work acting to give the change of motion; this was illustrated by a diagram of the parallelogram of forces giving the direction of the resultant force. The turning effort on the crank shaft and the stress on the material of the shaft at various parts of the stroke were illustrated, and the formula for calculating the diameter of the shaft was shown reduced to its elements, and analysed. The transmission of the motion from the crank shaft to the propelling apparatus by and through the intermediate shafting and coupling bolts was next dealt with, and the shearing action on the bolts, with the method of determining the section of iron or steel to resist fracture and ensure safety, was pointed out. The duty of the propeller, the effective and resisting forces at work in the propeller itself, as well as the vessel to be propelled, were analysed, and the net power available for moving the vessel through the water at a certain rate of speed was obtained from assumed data. The power expended in working the pumps, especially the circulating pump, was shown and illustrated by an example worked out from rules and assumed data, and the lecturer closed by expressing the hope that he had given some ideas which might be productive of good to some of the juniors present, and, although he made no claim to originality in what he had put before the meeting, he wished to interest and draw out the younger members and graduate section of the Institute and lead them to think about the theoretical as well as the practical side of their business.

AMALGAMATION OF ELECTRICAL INTERESTS.

The United Engineering Company, Limited, have amalgamated with Messrs. Statter & Co., of West Drayton, under the title of the Electrical Engineering Corporation, Limited. The Corporation has thus large works at West Drayton for engines and heavy electrical plant, and a smaller works in Lambeth for switches and accessories, and offices in Victoria Street. Messrs. Statter, Manville, & Madgen are managing directors.

THE OIL TRADE.

At present we hear a great deal about the tendency towards a national organisation of our different industries so that the claims of employers and employed in all parts of the country may be duly considered. It is quite evident however, that if we are to retain Free Trade—and of that there can be little doubt—the movement must become international, as indeed it has already become in some departments. The latest example is that of the Scotch oil trade. A few days ago the representatives of the Scotch companies met in London the representative of the large syndicates which control the whole of the American oil trade, to consider the claim of the Scotch companies for a rise in the prices of scale and candles. After fully discussing the subject it was agreed to defer the decision until the American representative had visited the Continent and made inquiries into the conditions of the trade in the different countries. Improved communication and the telegraph has compressed the globe into a very small part of its former dimensions, and made each country to a large extent dependent on what is being done in every other country with which it has business relations.

THE COTTON TRADE.

Quite a revolution has taken place in the business of cotton buying in Liverpool. The custom was for all users of cotton to purchase their requirements through brokers. It was quite the exception for a spinner to buy direct from a merchant. The Oldham Cotton Buying Company, however, has now been in operation for some time, and the results of the past three months are noteworthy. This company, it may be observed, acts for spinners, but is "boycotted" by the Liverpool Brokers' Association. The cash turnover for the three months ending last Saturday was £610,000, the number of bales bought being 67,000, against 52,750 in the corresponding quarter of last year. The trade profit was £2,587, and, after allowing for share interest, the sum disposable is £2,550, out of which the directors recommend a payment of 7s. per £100 of members' purchases. It is an open secret that many members of the Liverpool Association do business with the Cotton Buying Association, though it is contrary to the rules of the former association. Recently the directors have been considering complaints anent the irregularities. The feature of the market since the turn of the year is the advance in cotton caused by the speculative manipulation of jobbers. Merchants who sold for forward delivery in October last have had to buy spot cotton in Liverpool to meet their engagements, and in this way prices have been advanced. Spinners, it may be said, have "cornered" merchants, for the former as a body are well bought for the greater part of the season. In the meantime, spinning as a trade is remunerative, and satisfactory prices are being declared. Weaving, as distinct from spinning, continues a lean trade, for while yarn advances, cloth keeps all but stationary.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents)."

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

1889.

16776A. Alzugaray, J. B. ..... Universal furnace. (24th October, 1889).

6th January, 1890.

197. Lacey, R. G. ..... Sea anchor and oil distributors.
201. Tomlinson, J. D. ..... Cylinders for breaking fibrous material.
203. Howells, S. J. ..... Sea-oiling apparatus.
207. Whiteley & Whiteley... Spool winding machines.
209. Mayall, R., Jun. ..... Looms.
210. Thorp, T. ..... Pressure gauge.
212. Schloesser, G. H. ..... Paper-making machinery.
213. Macintire, J. ..... Steel and iron.
214. Canet, J. B. G. A. ..... Gun mounting.
220. Cutlan, F. ..... Nailing machine for boots.
221. Kenyon, Barnes, & Kenyon ..... Mangling machines.
227. Lake, H. H. ..... Railway vehicles (*Brill & Brill*).
236. Smith, C. ..... Projectiles (*Margary*).

7th January, 1890.

250. Roche & Roche ..... Cleaning tram lines.
255. Miles, S. J. ..... Furnaces.
256. Halladay, W. H. ..... Saw sharpening machines.
257. Halladay, L. P. ..... Saw swages.
258. Halladay, L. P. ..... Saw sharpening machines.
262. Butterworth & Butterworth ..... Tentering machines.
263. Seketeházy, J. ..... Portable framework for bridges.
266. Brock & Romero ..... Air pump.
267-8. Wise, W. L. ..... Manufacture of bricks (*Gregg*).
269. Lake, H. H. ..... Sewing machines (*Seam Machine Company*).
271. Justice, P. M. ..... Elevators (*Otis*).
277. Washburn, Croft, & Wheeler ..... Machines for working vegetable fibre.
284. Thompson, W. P. ..... Loading ships (*Paterson & Wade*).
285. Canet, J. B. G. A. ..... Mountings for guns. (8th June, 1889.)
286. Clark, A. M. ..... Rotary engines (*Almond & Freligh*).
288. Talbot, D. H. ..... Machines for stacking hay.
291. Rowe, R. ..... Forced draught fans.
293. Lake, H. H. ..... Cotton gins (*Chase*).
296. Groth & Constantine ... Post marking machines.
305. Clark, A. M. ..... Lace-making machinery (*Casse*).
306. De Susini, P. ..... Ether vapour engine.
307. Imray, J. ..... Piston rod packing (*Martin*).

8th January, 1890.

314. Holland, P. ..... Armour plating for ships.
319. Grimshaw, W. D. ..... Boiler furnaces.
321. Parker, C. F. ..... Air signal for collieries.
324. Siddall & Chadderton Carding engines.
329. Lister, H. ..... Looms.
331. Priestley, Pearson, & Hirst ..... Steam engines.
335. Hitchon, A. ..... Beaming yarns.
344. Craig, G. ..... Coke ovens.
345. Horn, W. W. ..... Car axle lubricator (*Sherman & Mitchell*).
346. Bryden & Stansfield ... Mules.
351. Jones & Jones ..... Machinery for rolling metal.
354. Olpherts, W. G. ..... Chair sleepers.
362. Bellis, Morcom, & Pain Steam boilers.

9th January, 1890.

366. Ormondroyd, G. ..... Spinning machinery.
368. Logier, E. ..... Rail chair.
371. York Street Flax Spinning Company, Ld., & McKibbin ..... Wet spinning frames.
373. Hunt, G. H. ..... Furnaces.
374. Turton & Sons, Ld., & Roberts ..... Railway springs.
375. Whiteley, Whiteley, & McKay ..... Machines for dyeing yarn.
385. Birtwisle, W. ..... Mowing machines.
388. Houghton, J. ..... Endless chain brake.
389. Kenyon, J. H. ..... Looms.
390. Tweedale, S. ..... Carding engines.
393. Wilson, R. C. ..... Evaporation of brine.
396. Glaze, W. ..... Lubricating wheels and axles.
398. Wild, W. ..... Evaporation of liquids.
409. Hay & McIntyre ..... Lubricating engines.
410. Lyon, J. G. (of the Firm of Gourlay Brothers & Co.) ..... Steam engines.
414. Tangye & Floyd ..... Differential pulley blocks.
415. Tangye & Floyd ..... Pulley blocks.
416. Guy, C. W. ..... Extracting the juice of sugar cane.

10th January, 1890.

434. Jackson & Carter ..... Manufacture of articles from metal.
437. Hattersley & Hill ..... Looms.
439. Laffon, D. ..... Segment wheel and expanding axle box.
443. Wild, J. ..... Governors.
447. Ward, H. E. ..... Manufacture of axes.
449. Jones, W. P. ..... Breechloading small arms.
451. Yeadon, J. ..... Looms.
456. Marshall & Burgon ..... Friction driving gear.
457. Richardson, H. ..... Weighing machine.
464. Jackson, C. L. ..... Mandrels.
468. Harrington, G. F. ..... Firearms and projectiles.
470. Hickling, W. E. ..... Sewing machines.
472. Jones, C. ..... Furnaces for treating refuse.
474. Blagburn, C. ..... Treating liquids and solids with gases.
483. Bergman, O. W. ..... Firearms.
496. Lucas, A. H. ..... Hulls and keels for steamships.

11th January, 1890.

500. Gimson, Gimson, Gimson, & Gimson ..... Edge setting and burnishing machines.
506. Linkleter, J. ..... Sea anchors.
508. Maule, W. ..... Pinion cutting tool.
510. Wilson, T. E. ..... Concentration of liquids by evaporation.
518. Ball, W. ..... Glands and stuffing boxes.
522. Godchaux, P. A. ..... Printing in colours. (4th October, 1889.)
524. Lawson, G. ..... Boiler furnaces.
525. Thomson, T. ..... Submarine tunnels.
526. Thompson, W. P. ..... Matrice making machines (*Landsberg & Köhler*).
527. Harry, R. H. ..... Band saw machines.
528. Norton, T. ..... Vices.
535. Rhodes, G. ..... Boiler furnaces.
536. Holt, J. ..... Potato diggers and separators.
537. Thompson, W. P. ..... Tuyeres for blast furnaces (*Kromberg*).
548. Haddan, R. ..... Removing timbers from mines (*Kirschniok*).
549. Hewins & Hardy ..... Stopping and starting tramway cars.
553. Ellis, J. D. ..... Manufacture of metallic tubes, &c.
554. Candy, F. J. ..... Collapsing boats.
558-9. Wheeler, N. ..... Sewing machines.
562. Walker, B. ..... Forging presses.
565. Correll, F. ..... Collecting and removing floating débris in rivers.
567. Serrin, L. M. V. ..... Weighing machines.

ELECTRICITY.

6th January, 1890.

217. Binswanger & Croft ... Arc lamps.
232. Hopkinson, Hopkinson, & Grindle ..... Dynamo-electric machines.

7th January, 1890.

241. Whalley, A. ..... Telephone switchboards.
249. King, W. F. ..... Dynamo-electric machines.
272. Haddan, R. ..... Electromagnetic despatch apparatus (*Williams*).
274. Natterer, A. ..... Electric bells.
302-3. Lake, H. H. ..... Secondary batteries (*Alexander*).

8th January, 1890.

350. Epstein, L. ..... Batteries.

9th January, 1890.

402. Graf, F. A. ..... Electric clocks (*Nahler*).
425. Richardson & Moon ..... Electric mains.

10th January, 1890.

475. Sack, J., and the Firm Von Maltitz & Ziesel ... Telegraphic communication.
488. Sappey, M. ..... Primary batteries.

11th January, 1890.

534. Binswanger & Coates ... Electrical switches.

CHEMISTRY.

6th January, 1890.

237. Brown & Irvine ..... Extracting gold.

7th January, 1890.

260. Stears, J. ..... Gas making.
283. Smith, A. T., Jun. ..... Hydrochloric acid, &c.
309. Kay, T. ..... Treatment of sewage.

8th January, 1890.

316. Chaster, J. E. ..... Extraction of metals.
343. Cotton & Crowther ..... Making gas.
357. Wöhle, Irwine, & Jacob Dextrine.

9th January, 1890.

381. Townsend, O. C. ..... Nitrate of potash.
411. Hennebutte, H. J. E. ... Sulphate of copper.
419. De Lambilly & Chabrier Ammonia and cyanogen.
424. Smith, W. J. ..... Ore concentrating machinery.

10th January, 1890.

448. Spence, Spence, & Esilman ..... Alum.

11th January, 1890.

530. Christy & Carter ..... Separating iron from bones.
552. Sellar, W. C. ..... Gas producers.
560. Twynam, T. ..... Copper.
569. Kern & Sandoz ..... Blue colouring matter.

MISCELLANEOUS.

6th January, 1890.

200. Walker & Brown ..... Drying or carbonising fabrics.
204. Lord, C. H. ..... Shuttles.
206. Gronwald & Oehlmann Sterilising apparatus.

7th January, 1890.

280. Robson, J. ..... Protecting iron surfaces from corrosion.
299. Driggs, W. H. ..... Percussion caps for projectiles.

8th January, 1890.

358. Bedingfeld & Jones ..... Sights for small arms.

9th January, 1890.

427. Hudson, P. V. ..... Sounds transmitted through water.

10th January, 1890.

438. Worsley, J. E. ..... Cleaning firearms.
480. Devonshire, E. ..... Purifying water.

11th January, 1890.

502. Thompson, J. K. ..... Briquettes of coal.
540. Wade, J. L. ..... Lubricating oil.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1888.

14400. Hutchinson. 14444. Helwig. 14614. Royston.

1889.

116. Stone.
252. Salomon.
360. Wallace.
438. Kirkaldy.
564. Laffitte.
595. McDonnell.
1038. Rees.
1119. Fairbairn.
1317. Robinson.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Combing Machines.—*F. Illingworth, Bradford.*—Certain improvements are here made in the operation of the drawing off rollers of combing machines of the "Noble" class. The object is to distribute the wear and tear of the fluted part of the rolls over the whole surface. The illustrations give an elevation of a pair of drawing off rollers with the improved apparatus attached. The fluted drawing off rolls are mounted in the frame of the comb, and driven by the spur wheel D connected by the usual train of gearing to the driving shaft. To distribute the wear upon the surfaces of the rolls, they are given an up and down motion in the direction of their axes. On the driving spindle L of the fluted roll A is secured a worm F which drives

through the set of gear wheels and worm Q, P, G, H, and I, the gear wheel J. In the gear wheel J is secured a pin which works in a horizontally cut slot in the saddle-shaped piece K. The saddle-piece K is supported by its lugs to the spindle L, and the worm F which is fixed to the spindle L is between the lugs. The spindle of the other roller B is secured to the top lug of the saddle piece K by a slotted clip N. Thus as the roller A revolves, the gear wheel J also revolves, and the pin secured to it causes the saddle-piece K to rise and fall. The saddle piece K in rising and falling moves the rollers A B with it, the former being moved by the lugs of the saddle piece working against the worm F fixed to its shaft. Claim: The combination of the worm F secured on the spindle L with the saddle K and intervening worms and wheels and the slotted clip N.—No. 1212. January 23rd, 1889. 6*d*.

Appliance for Cutting Milling Tools, &c.—*T. Gare, Stockport.*—The appliance is made for use upon lathes, to which it can be readily fitted. Figs. 1 and 2 show the appliance fitted to a screw-cutting lathe without gap. Upon the cross feed slide rest B of the lathe is a carrier or support F on which the object G to be cut is mounted on a stud H. One end of the support F is hinged to the adjustable slide T, and the other end carries a pin L for tracing the former M upon the adjustable bracket O. The tool P which operates upon the object G to be cut is fixed to a mandril B', and caused to rotate between the centres of the lathe. The object G is moved against the rotating tool P by the cross

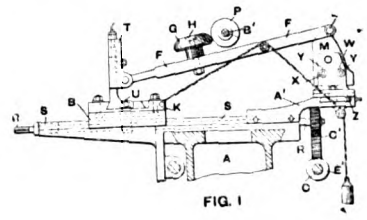

FIG. 1

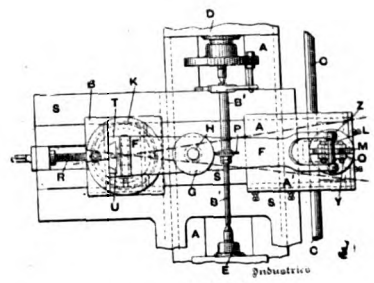

FIG. 2.

feed screw R worked automatically from the back shaft C. The stud supporting the object G may be provided with a division plate, to effect the proper number of cuts in the object. Figs. 3 and 4 show a modification of the apparatus fitted to work in the gap of a lathe. The principle of the apparatus is the same as already described. The hinged end of the support F is made vertically adjustable on the bracket U which overhangs and is radially adjustable on the cross feed slide rest B. The former is in this case one of a number cut from a disc Q supported upon a spindle. Use can thus be made of either former by turning them upon the spindle. By adjusting the brackets U and O the support

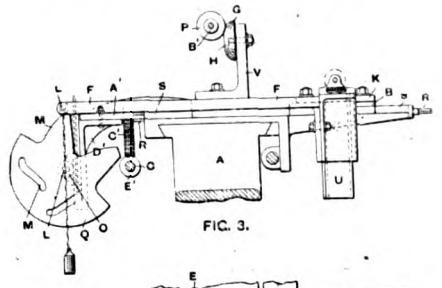

FIG. 3.

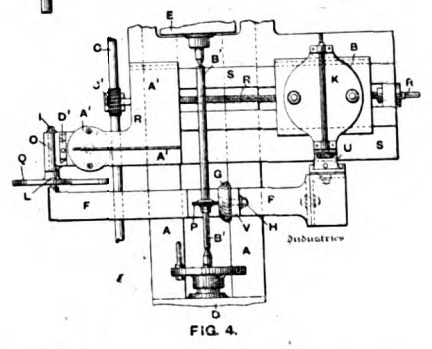

FIG. 4.

F may be fixed and the object G cut at any desired angle. To cut twist drills the blanks are moved forward against the cutter by a screw of the desired pitch actuated by weight and cord. Claims: (1) The employment of a carrier or support F, adapted to bring the object G to be cut against a milling tool P, rotating always in the same position with reference to the figures generally; (2) the combination with a sliding rest B of a carrier or support F as specified in the preceding claim, one end of which is hinge-like attached thereto and the other end thereof controlled by a former M; and (3) and (4) referring to the method of cutting twist drills and support for cutting differently shaped cutters.—No. 872. January 17th, 1889. 8*d*.

Damping Warps in Looms.—*J. Grime & T. Atkinson, Accrington.*—This invention renders the use of loose steam for damping the warps unnecessary. The improved appliance consists of a hollow cylinder extending across the loom and under the warp between the warp beam and the healds. The hollow cylinder is filled or partially filled water with soap or glycerine, and it has a slot extending lengthwise along its upper surface. Through this slot is inserted a bar of wood covered with flannel or other porous material, the upper edge of the bar projecting beyond the circumference of the roller. The warp passes over and bears upon the upper edge of the flannel covered bar, and the water or liquid contents of the cylinder ascends the flannel covering through capillary attraction, saturating the flannel, and by contact between bar and warp, damping and softening the latter. Claim: The improved apparatus wherein is comprised a liquid-containing vessel and a device for conveying the liquid to the warps through capillary attraction for the purposes aforesaid.—No. 3239. February 23rd, 1889. 6*d*.

Veneer Saws.—*D. P. A. Mersing, Galatz, Roumania.*—This improvement enables vertical veneer saws to cut in both directions, upward and downward. This is attained by the use of peculiarly formed saw teeth. The teeth have an M shape, and between the teeth are clearance spaces nearly the width of the teeth. The teeth are set so as to cross the plane of the saw at both points. The inner and outer parts of their legs are the cutting surfaces, and they are bevelled in opposite directions to cut in the manner described. One claim is made for the form of tooth described.—No. 17199. October 30th, 1889. 6*d*.

Rolling Mills.—*J. Jardine & J. T. Brassington, Motherwell.*—The novelty in this invention is the employment of hydraulic mechanism for regulating the distance of the moving rolls from the fixed rolls and sustaining the stress on them due to the work being performed. In the accompanying illustrations Fig. 1 is a transverse vertical section of the mechanism applied to a horizontal mill, and Fig. 2 is a modified form of the hydraulic cylinder as applied when the head of the housing is cast specially. Referring to Fig. 1, A is the hydraulic cylinder firmly attached to the steel or iron piece B, which is let into the housing in a step-like manner. In the hydraulic cylinder works the ram D, which is connected by the shaft E to the upper block F of the bearing of the upper roll G. The lower half of the bearing H is supported by a ram L, whose under surface is constantly exposed to the full water pressure from the accumulator supplying the water to work the mechanism. The area of the under surface of the ram L is sufficient to raise the weight of the upper rolls, the ram D, and their connections. The water is regulated to and from the cylinder A by the valve C, which is operated by a hand lever O. A spring loaded safety valve P is placed to relieve excessive pressure in the cylinder. To raise the rolls the hand lever O is

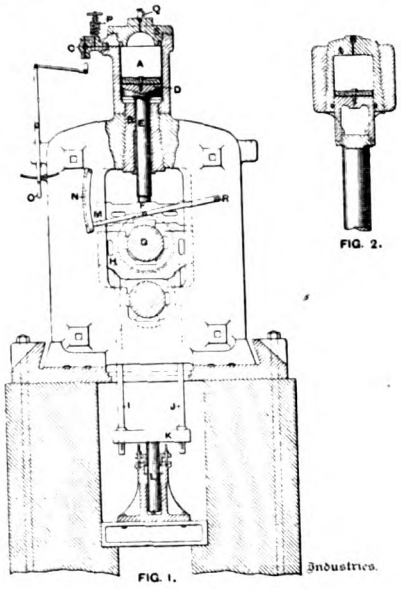

FIG. 1.

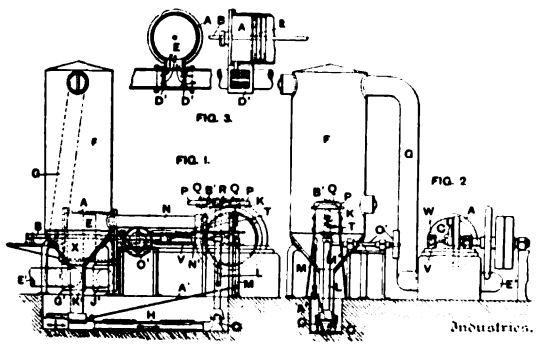
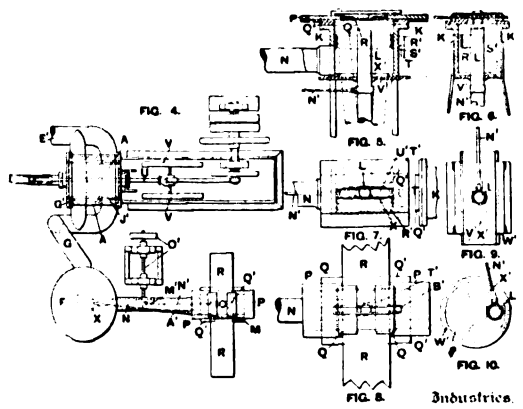
FIG. 2.



moved to a position which communicates the cylinder with the exhaust passage. The pressure on the top of the ram D is thus removed and the roller is pushed up by the lower ram L. When the height required is reached the handle O is moved to central position and all communication to the cylinder closed. To lower the rolls the handle O is moved to a third position, and the full pressure of water admitted to the top of the ram D, and so the rolls are pressed down. Claims: (1) In rolling mills the use of hydraulic cylinders such as A to depress the upper roll and resist its upward movement while passing metal as determined by the position of valves or cocks, or valve or cock such as C, together with any ordinary and well-known means of holding up and lifting the lower sliding blocks or chocks carrying the lower bearings; (2) in rolling mills the use of hydraulic cylinders such as A to depress the upper roll and resist its upward movement while passing metal as determined by the position of valves or cocks, or valve or cock such as C, together with lower hydraulic rams such as L for holding up and lifting lower sliding blocks or chocks; (3) in rolling mills the use of hydraulic differential pistons such as D with water pressure above and below, controlled by a cock or cocks such as C, so as to depress, resist, or lower an upper roll operating on the water communication above and below by a cock or cocks such as C; (4) the combination of parts forming the improved hydraulic adjustment for rolling mills as shown in the accompanying drawings whether applied to horizontal or vertical rolls.—No. 1986. February 4th, 1889. 8*d*.

Appliance for Removing Screw Propellers.—*J. Bower, London.*—The appliance is intended for removing propellers from their shafts while standing in dry docks, &c. The appliance consists of two rectangular pieces of metal placed face to face between the boss and bearing of the propeller. In the faces of the blocks are recesses to receive a tapered pin, which is driven down between the blocks to separate them and so force the propeller off. Two pairs of blocks are used, one on each side of the shaft, and the blocks are connected to rods which are held together in pairs by clams. The ends of the rods rest upon the ground to support the blocks in their place whilst the tapered pins are driven in. Claims: (1) In a device for removing screw propellers and wheels from shafting, the combined arrangement consisting of two or more sets of "dies" and taper pins, each set consisting of two dies or blocks and one taper pin, with legs welded on to the dies or blocks, with or without wedges; (2) in a device for removing screw propellers and wheels from shafting, the employment of dies or blocks with or without legs and taper pins as described.—No. 4702. March 18th, 1889. 8*d*.

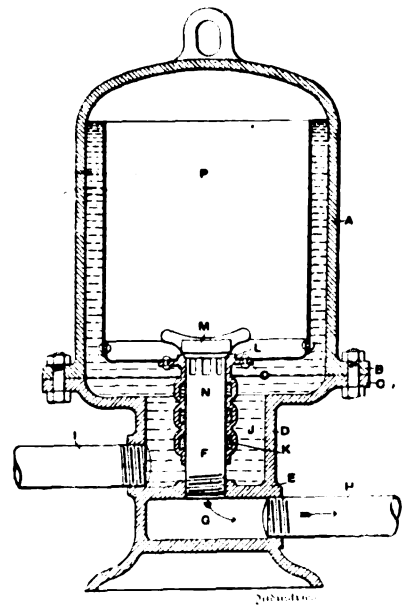


Digitized by Google

RAILWAY SLEEPERS AND CHAIRS.—*J. Woodward, Dublin.*—The sleepers consist of an inverted T-shaped length of wrought iron, of suitable proportions. In the upper flange of the sleeper are cut two notches for the reception of the chairs. These notches are cut only half way down the flange. Each chair has upon its sides grooves to receive the edge of the notch, and under the chair is a deeper groove, to pass over the half of the flange not removed. The chair is placed in the notch, and afterwards bolted to the bottom part of the inverted T-shaped sleeper, on which it rests. Three claims are made for the sleeper and chair described, and the use of a bolt at the top edge of the chair for securing the rail in the chair.—No. 6,752. April 20th, 1889. 6*d.*

SAND BLAST MACHINERY.—*J. C. Peacock, Birmingham.*—In conducting the sand blast process a stream of sand is projected by a jet of air produced by an air compresser or exhauster, and forced against the surface of the glass. Improvements are here introduced in certain parts of the machinery used in the above-described process. Fig. 1 shows a side elevation, Fig. 2 an end elevation, and Fig. 4 a plan of the complete apparatus. Referring to the figures, A is the cylinder of an exhauster, E its piston having a rod which passes through both ends and supports the piston centrally on slides at each end. Under the exhauster cylinder A are valve boxes fitted with Indiarubber flap valves D^1 (see enlarged view Fig. 3). Placing the valves underneath the cylinders prevents the sand passing into the cylinders. F is a wrought iron reservoir or air chamber connected to the exhauster by a pipe G leading to the valve box. E^1 is a pipe conducting the exhaust from the exhauster. The

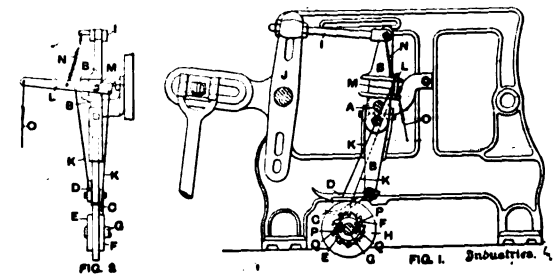
bottom part of the air chamber X forms a chamber for the sand which falls to the pipe K^1, and thence through the sand valve into the pipe H. The sand valve is opened by a lever M and connecting rod A^1. A current of air is admitted immediately below the sand valve and carries the sand along the pipe H into the bell-mouthed end of the pipe L. A second pipe admits air to the bell-mouthed end of the pipe L, and carries the sand up the pipe to the glass being operated upon. The tube L is mounted on trunnions to enable it to be oscillated at the top end, as shown by the dotted lines Fig. 5. The glass R being operated on is held in position by the Indiarubber flaps Q and the sliding pieces P, which are strapped together by B^1. The sand, after operating upon the glass, is carried back to air chamber F by a pipe N, where it falls to the bottom X, and the air is drawn off by the exhauster. Claims: (1) Improvements in machinery used in the sand blast process hereinbefore



described and illustrated with the accompanying drawings, that is to say, the construction of the piston employed in the exhauster which is evenly balanced and forms a floating mass in the cylinder, a continuous rod which is a little cambered and supported on slides at each end of the cylinder; (2) the construction and arrangement of parts of the machinery used in the sand blast process hereinbefore described and illustrated, where a sheet of glass or other material of any size or shape may be placed on the upper surface of a rectangular or other shape box, and operated upon by a constant stream of sand drawn by the air from the exhauster, and equally distributed on the surface of the glass by a vibrating or oscillating pipe, having a to and fro, or an angular, or a circular, or a semi-circular, motion caused by the said pipe L sliding in the slot X^1 shown at Figs. 9 and 10 and working on trunnion arms, or by other means; the motion which is obtained by a disc and lever, a rack and pinion, or other mechanism.—No. 18728. December 22nd, 1888. 8*d.*

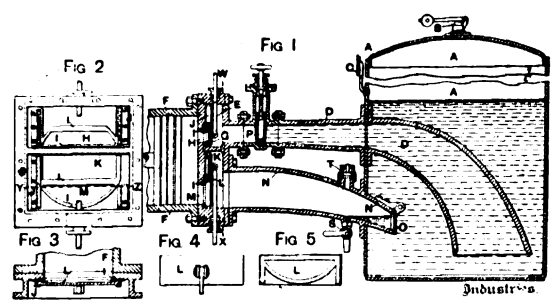
GATE VALVES.—*J. Dewrance, London.* (*R. M. Pratt, Hartford, U.S.A.*).—The invention refers to that class of valves known as straight-way gate valves. The valve chamber is provided with ports and a gate for opening and closing the ports. The gate is of a tapered cross-sectional form, and its seatings are made removable, being held in position between the body and the gate by a holder which may be removed by removing the bonnet or cover of the valve chamber. The gate is raised and lowered by a screw passing through the valve chamber cover. Claims: (1) The improved gate-valve, constructed substantially as herein described, and having removable seats and a removable seat-holder or seat-holders held down by the bonnet; (2) in a gate valve provided with removable seats, mounting such seats in a removable seat-holder or carrier; (3) in a gate valve provided with removable seats, mounting such seats in grooves in the valve body, the same being held down in the said grooves by means of a removable seat-holder or frame; (4) in a gate valve provided with removable seats, mounting each seat in a separate seat-holder or plate adapted for being removed together with the seat from the valve body.—No. 2757. February 16th, 1889. 8*d.*

BELLS FOR SIGNALLING.—*C. Parkin, Liversedge, Yorkshire.*—The striking mechanism of the bell is combined with an index-hand, which registers upon a dial the number of strokes made on the bell. The index hand and striking hammer are operated simultaneously by a suitable arrangement of ratchet wheel pawls and levers, which are worked by the operator pulling a lever the required number of times.—No. 17,048. November 23rd, 1888. 6*d.*



STEAM TRAPS.—*B. Thoens, New Orleans, U.S.A.*—This invention relates to steam traps for discharging the water of condensation from radiators, steam heating coils, and other steam apparatus. The apparatus consists of an outer closed vessel A, and an inner vessel P, opened at the top and free to slide up and down upon a tube F. The sleeve K of the vessel P is fitted with packing material to make a liquid-tight joint, and the top edge of the sleeve is bevelled to form a seating for the valve-shaped top of the tube F. Openings N are cut in the top edge of the tube F to form communication between the vessel P and exhaust pipe H when the former is depressed. The trap works as follows:—The trap being empty, the vessel P, with its sleeve, sinks down by gravity, leaving the passages N open or exposed. As steam enters by the inlet pipe I the air is driven out of the trap, and the incoming water accompanying the steam gradually fills the well or chamber D, and rises in the casing A, thereby lifting the vessel or float P until the openings N are closed by the sleeve, as shown in the drawing. As the water continues to enter, it rises around the float and enters the same by flowing over its top, until the weight of water therein becomes sufficient to depress the float, whereupon the water passes through the openings N, and thence through the tube F and chamber G into the outlet pipe H. If the water ceases to flow, the steam will blow what

remains in the float out through the pipe F until the float becomes light enough to rise and close the openings N, after which the parts remain in that position until more water accumulates, when the operation is repeated. Claims: (1) A steam trap, having a closed chamber, an inlet pipe, a vertical tube or pipe rising therein, connected to an outlet pipe, and having openings at its upper end, and an open float rising and falling on the vertical tube or pipe to cover and uncover said openings; (2) in a steam trap, the combination with a closed casing, having a pendant well, of a vertical tube or pipe rising in the well and having openings at its upper end, a sleeve rising and falling on the tube or pipe, an open float carried by the sleeve, and inlet and outlet pipes; (3) in a steam trap, the combination of a closed casing, having a pendant well provided with a bottom wall, a tube tapped through said wall, rising therefrom and having openings and a valve at its upper end, a sleeve rising and falling in the well on the tube and having a valve seat on its upper end, an open float carried by the sleeve, and inlet and outlet pipes; (4) a steam trap, consisting of a horizontal plate, formed with a central pendant well having a bottom wall, a closed bell-shaped casing surmounting the horizontal plate, a float located in the bell-shaped casing and open at its top, a vertical tube secured to the bottom wall of the well, rising in the latter above its horizontal top plate and having its upper end provided with a valve and lateral orifices, a sleeve extending down into the well from the bottom wall of the float, sliding up and down on the valved pipe, and having its upper end opening through the bottom wall of the float and there provided with a valve seat.—No. 16,204. October 15th, 1889. 6*d.*



RAILWAY CARS FOR CONVEYING SHIPS.—*W. Smith, Aberdeen.*—The object of this invention is to provide a car whereon the ship will be practically waterborne, at the same time permitting the necessary flexibility of the car vertically and laterally. A series of hydraulic cushions are employed to line the sides and bottom of a cradle-like superstructure of the car. These cushions are formed of flexible and compressible U-shaped tubes: they are filled with water, and the weight of the vessel pressing on them is thus counteracted by the hydrostatic pressure due to the water in their vertical parts. The cradle-like superstructure for supporting the hydrostatic cushions are formed of U-shaped sections, each of a width and shape to correspond to the sectional outline of the ship at the part to which it is applied. The several sections are hinged together by tranverse hinges at the base, so as to maintain an invariable distance apart, whilst permitting flexture of the series in the vertical plane. The superstructure is carried upon a wheel base running upon several parallel lines of rails. The wheel base is composed for each pair of rails of trucks extending the whole length of the car, the trucks being coupled together so as to maintain an invariable distance apart whilst permitting free swivelling or lateral motion guided only by the wheel flanges against the rails. One truck only of each set is connected to the superstructure by a centre pin; the remaining trucks support the superstructure upon rollers which allow of a free lateral movement. Five claims are made.—No. 7529. May 6th, 1889. 8*d.*

LOOM DOBBIES.—*A. Sowden, Baildon, Yorkshire.*—This invention consists of improved apparatus for operating card barrel whereby the barrel may be caused to rotate or work in its ordinary course, or to be reversed and worked in the opposite direction without reversing any other part of the loom. The reverse motion is of instant application and effect, and the lagging back is effected two picks for each card. According to this invention, on a stud A is a vertical and preferably broken-backed lever B, at the foot of which are two catches C D (push and pull catches) which engage as required with two catch wheels E F on the axis G of the card cylinder H. The upper end of the vertical lever B is connected by an adjustable rod I with the rocking lever J of the dobby. The rocking lever imparts the requisite

motion to the vertical lever B, and thereby operates the catches C D. The catches C and D are connected by string or wire K K with a cross lever L on a stud M carried by the broken-backed lever B. The lever L is so arranged that when pulled down by cord or string O the pulling catch D will engage with its catch wheel E, and so turn the barrel H in one direction; but when the cross lever L is raised by the spiral spring N, the other or pushing catch C will engage with its wheel F, and the barrel H will be turned in the opposite direction. The reversing of the barrel is effected by simply pulling down the cross lever L, which will lift the pushing catch C out of gear with its wheel F, and bring the pulling catch D instantly into operation without any other part of the dobby or loom requiring to be reversed or interfered with. Claim: (1) Reverse acting catches mounted upon an operating lever, such as B, the catches being controlled by means of cords or wires K operated through a lever such as L.—No. 18868. December 27th, 1888. 8*d.*

OBTAINING MOTIVE POWER.—*F. W. Cleveland & L. Dove, London.*—Power is obtained by the application of tapered tubes for increasing the effective pressure and decreasing the resisting pressure of the water used in driving the motor. The apparatus is based upon the principle of injectors used in hydraulic machinery, in which water passed into a tapered tube at the larger end is ejected through the small end into a high pressure by a low pressure. The apparatus is constructed with a cylinder, piston, crank shaft, fly wheel, &c., similar to ordinary steam engines. To the end of the cylinder are attached the parts by which the motive power is obtained. A is a water and air holder answering to a boiler of a steam engine, and fitted with safety valve B and pressure gauge C. The holder A is in communication with the rear end of the cylinder F by tapered tubes D and

N. The passage of liquid through the tubes is regulated by the valves G and L, which are operated by the motion of the engine. In working the apparatus the holder is partially filled with water, and air at a pressure of 100lb. introduced into the remaining space. The water is now admitted to the cylinder by the tube D and by the principle involved the water as it is delivered from the small end of the tube to the cylinder should be of a higher pressure than that in the holder. The water thus admitted to the cylinder acts upon the piston and makes the outstroke of the engine. Upon the instroke of the engine the valve G is closed and the valve L opened to exhaust the water through the tube N. The exhaust taking place through a tapered tube as shown a less pressure in the cylinder should be sufficient to return it to the holder A. Thus, according to the principle of the apparatus, water is introduced to the cylinder at a high pressure and exhausted at a lower pressure, whilst the pressure in the holder A remains constant. Claims: (1) The combination with a water holder A and water and an air pressure in A acting on the water and a suitable hydraulic engine for the utilisation of the water of the tapered tubes D and N; (2) the arrangement of apparatus and water with air pressure substantially as described and illustrated in the accompanying drawings for the obtainment of motive

Digitized by Google

power; (3) the improved form of hydraulic engine consisting of two or more single acting cylinders with pistons and other usual parts having an inlet and exhaust slide valve working at end of each cylinder independent of each other.—No. 7106. April 29th, 1889. 8*d.*

GENERATION OF STEAM WITH GASES.—*O. W. Ketchum, Toronto, Canada.*—A boiler is here described in which gaseous fuel is consumed under pressure, and the products of combustion are mixed with the steam produced from the water in the boiler, thereby doing away with the necessity for having a chimney. The illustrations show Fig. 1, a section upon a side elevation of the boiler, and Fig. 2, a section upon an end elevation. The boiler A is constructed with a dome B connected up by the pipes C. Within the boiler is the combustion chamber D, lined with refractory material E. F is the discharge pipe for the products of combustion, leading to a box F^1 which receives the feed water, and from there bending down into the water of the boiler, and terminating in a perforated tube G. The products of combustion

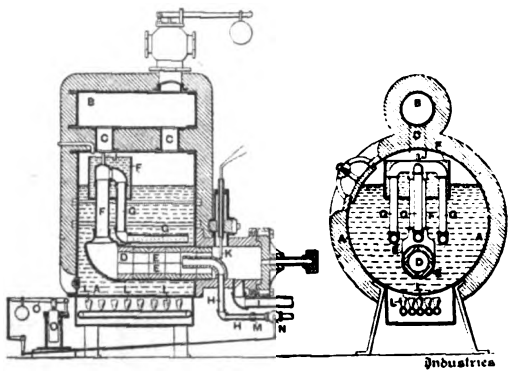


FIG. 1.

FIG. 2.

thus pass into the water, and ultimately mix with the steam. H is a pipe for supplying the gases, I the pipe for supplying air. K is a wire of platinum inserted in the combustion chamber, and electrically heated to cause ignition of the gases. The ignition of the gases, after the apparatus has been at work a short time, may be caused by the heated state of the lining of the combustion chamber, but if the electric current is used continually an automatic device for controlling the gas supply may be applied. A plunger O subjected to the pressure in the boiler is also used to control the supply of gas by acting upon the valve N, and gradually closing it when the pressure exceeds a certain amount. The gas jets L are for heating the boiler at starting to bring the pumps into use for supplying the gas and air to the combustion chamber at a pressure higher than the pressure in the boiler. Claims: (1) The combination of the closed chamber D having the air and gas supply pipes, the pipe F, and the feed water box F^1, through which pipe F passes; (2) the combination of the closed chamber having the air and gas supply pipes and the electrically charged wire K, the pipe F, and the feed water box F^1, through which the pipe F passes; (3) the combination of the closed chamber D, the air pipe entering said chamber, the gas supply pipe having cock M, and electrically charged wire extending into said chamber and having an armature connected with the cock M; (4) the combination of the closed chamber D having the air and gas supply pipes, the pipe F having the extension J, and the feed water pipe F^1; (5) the combination of the closed chamber D having the air and gas supply pipes, the pipe F, and the downward extension G.—No. 1977. February 4th, 1889. 8*d.*

LEATHER ROLLING MACHINES.—*E. E. Sheldon, A. Mills, & J. Masters, Walsall.*—These improvements refer chiefly to the adjustment of the table carrying the leather to be rolled. Fig. 1 is a side elevation of a leather rolling machine to which the improvements have been applied, Fig. 2 is an end elevation, and Fig. 3 is a plan showing the lower table-adjusting mechanism with the upper screw and table removed, while Fig. 4 is a plan of the upper adjusting mechanism with the table removed. The machine resembles other leather rolling machines in that the wheel A is driven by belt or separate engine, and its revolution causes the roller B carried on suitable framing and guides to travel to and fro over the table C by means of the connecting rod D. The

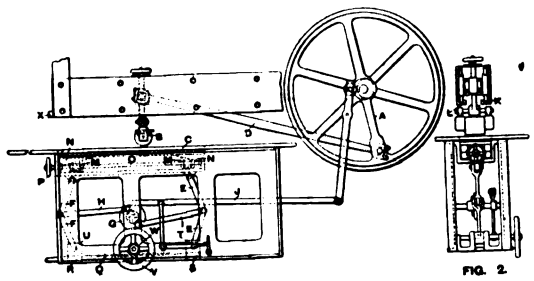

FIG. 1.

FIG. 2.

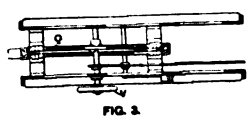

FIG. 3.

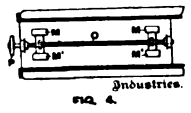

FIG. 4.

periodic raising and lowering of the table by means of the toggle levers E E, F F, and the wrist plate G and rods H I, together with the long rod J, lever, cam, and roller, is also well known and commonly applied. The invention consists in the application of novel contrivances for changing the level of the table which are shown in elevation at Fig. 1. Two wedges M M inclined in opposite directions act upon wedge surfaces N N fixed under the upper table. The wedge pieces M M are connected to the long right and left hand screw O, with a hand wheel P. By turning the wheel P the wedges M M are made to approach to or recede from one another, and thereby raise or lower the table to any desired proximity to the roller B independently of the lower adjusting arrangement. The lower adjusting arrangement consists of a rack Q having wedges R S at its extremities of the angle and direction as shown. These wedges carry the guide blocks T U, to which are pivoted the toggle-links E E, F F. The under surface of these blocks are inclined to suit the wedges, and as the blocks are only free to move vertically, when the hand wheel V is rotated in one direction the pinion wheel W moves the rack Q and the wedges simultaneously raise the blocks, and thus the table, the table always remaining in the same plane. The upper means of adjustment are provided to change the level of the table when a considerable movement is required. The lower adjusting arrangement is intended to alter the level of the table slightly to take the different thicknesses of leather, &c., in working. An arrangement for preventing oil dropping from the sliding piece carrying the roller B is shown in Fig. 2, and consists of two troughs K L inclined towards a third X, Fig. 1. Claims: (1) In a leather rolling machine the use of adjusting wedges such as M M, with a screw such as O for varying the level of the table; (2) in a leather rolling machine the use of a rack such as Q and wedges such as R S for the purpose of raising or lowering the table; (3) in a leather rolling machine the use of adjusting wedges such as M M, with a screw such as O in combination with a rack such as Q and wedges such as R S; (4) the contrivance described for preventing oil from dropping upon the leather from the sliding piece carrying the roller.—No. 1695. January 31st, 1889. 8*d.*

EVAPORATING APPARATUS.—*J. Frost, Huddersfield.*—The evaporating apparatus consists of a series of tubes A B. arranged one above the other, as shown in Figs. 1 and 2, The tubes A B are connected by elbows C and D, and they are heated by steam or hot water circulating through them. The solution to be evaporated is contained in the vessel O, from which it flows down to and over the tubes to a second vessel G. Plates H are provided as shown to collect and guide the solution to the centre of each succeeding pipe. Fig. 3 shows a plan of the plates and pipes; Figs. 4 and 5 differently shaped pipes. Claims: (1) The use and employment of a coil such as A, heated by steam, hot water, or air, for evaporating or concentrating solutions for the production of dyes or other like bodies, in combination with

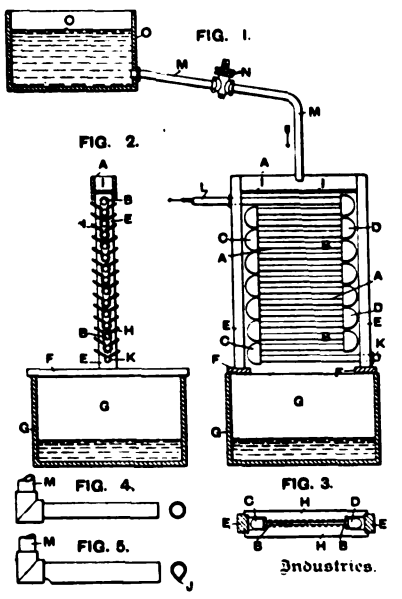

FIG. 1. FIG. 2. FIG. 4. FIG. 5. FIG. 3.

a tank or cistern containing the solution to be concentrated, and a tank or cistern for receiving the concentrated solution as it falls from the coil; (2) the coil A heated by steam, hot water, or air, when inclosed in a vessel or chamber, for evaporating or concentrating and distilling solutions; (3) in combination with the coil A and closed vessel of a bent pipe and conical pipe or "still head," for the purposes described; (4) the arranging of two or more coils A to act in conjunction with each other, and either exposed to the atmosphere as shown in Fig. 1, or inclosed in a vessel or chamber; (5) the combination with a coil or coils A of the inclined plates H, together with the trough I or its equivalent.—No. 1803. February 1st, 1889. 8*d.*

ELECTRICITY.

ELECTRIC REGULATING APPARATUS.—*A. L. Shepherd, London.*—The invention relates to electric regulating apparatus for use in connection with steam engines and other motors and dynamo-electric machines, and its main object is to provide simple and efficient means whereby the speed of the engine or motor will be varied automatically in accordance with the electromotive force of the current. To the spindle of a double beat throttle valve situated in the main supply pipe of the engine is attached a piston which works in a cylinder fixed over the valve chamber. By admitting steam to the cylinder the piston moves the throttle valve and regulates the supply of steam to the engine. The admittance of steam to the cylinder is controlled by an ordinary D slide valve, which is operated by electric mechanism. The electric mechanism may be the same as in the specification No. 10,209 of 1888; it comprises an electromotor consisting of a Pacinotti ring mounted between the poles of an inducing electro-magnet. The direction and duration of movement of the said electromotor is controlled by means of an electromagnet, solenoid, or other electrical device. The shaft of the electromotor is geared to the rod of the cylinder slide valve, the rod of the valve terminating in a rack. The operation of the apparatus is as follows:—The electric mechanism of appliance is coupled as a shunt circuit to the parts where a constant potential is desired. Any rise or fall of the potential at this point causes the electric mechanism to move the slide valve and admit steam to the cylinder, and so cause the piston to open or close the throttle valve. Claims: (1) A regulating apparatus comprising an electromotor arranged to operate a valve for controlling the distribution of fluid under pressure to a cylinder the piston of which is connected with a throttle valve or other regulating device for the purposes above specified; (2) the improved apparatus constructed as described.—No. 2003. February 4th, 1889. 8*d.*

TELEPHONES.—*E. Gwosdeff, St. Petersburg.*—The transmitter and receiver of the telephone described in this invention each have an iron diaphragm arranged between two horseshoe magnets, whose bobbins are wound with double wires, one being in communication with the line, and other short-circuited on itself, so that the resulting current is equal to the sum of the currents induced in each pair. The iron diaphragm is connected by a non-magnetic rod, or rods, to a non-magnetic diaphragm of larger diameter than the iron one. Figs. 1 and 2 represent in diagram the principle of construction of the proposed telephone—Fig. 1 being the transmitter and Fig. 2 the receiver. Figs. 3, 4, and 5 represent the construction of a complete apparatus, Fig. 3 being a plan view (the upper half being removed), Fig. 4 a section on the line X, Fig. 3, and Fig. 5 a section on Z, Fig. 3. D is a diaphragm of iron arranged between the poles of two horseshoe magnets M H; B and G are induction bobbins fixed on the polar extensions of the magnets M H, and are connected together in such a manner that the currents induced in the bobbins by the movements of the diaphragm D shall be added the one to the other, that is to say, that the resulting current shall be the sum of all the currents. The diaphragm D is placed at such a distance from the two magnets, that each exercises an equal attraction on the diaphragm. The screw ring A, in which the

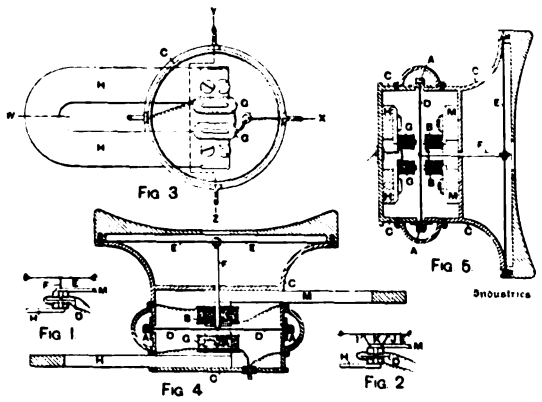

FIG. 3. FIG. 5. FIG. 1. FIG. 4. FIG. 2.

diaphragm D is fixed by its edge, provides for the exact regulation of the position of the diaphragm. In front of the magnets M H^1, a second diaphragm E is fixed, by its edge, to the box C of the apparatus. This diaphragm E is of a diameter greater than the diaphragm D, and is made of a non-magnetic material, such as wood, ebonite, aluminium, or aluminium bronze. The diaphragm E is connected, by means of an aluminium rod F, to the centre of the diaphragm D, the rod F passing between the bobbins B B of the upper magnet M. In the transmitter, the point of attachment of the rod is at the centre of the diaphragm E, as in Fig. 1, but in the receiver the diaphragms are connected by two or more rods as in Fig. 2. The method of connecting the diaphragms permits of the reproduction of sounds in a loud tone without the necessity of raising the voice. Claim: The improvements in magnetic telephony above described, and characterised by the employment of two diaphragms, one of which is of iron, and arranged between the bobbins of two horseshoe magnets—the other of non-magnetic material, and of a diameter greater than the first, and connected to the centre of the iron diaphragm by one or more rods made of non-magnetic material, the point of attachment of these rods being at the centre of the non-magnetic diaphragm when the apparatus is to serve as a transmitter, but at a distance from the centre when the apparatus is used as a receiver, the bobbins of the magnets being in all cases connected together in such a manner that the current resulting is equal to the sum of the currents induced in each pair.—No. 2137. February 6th, 1889. 8*d.*

MISCELLANEOUS.

SOFTENING AND CLARIFYING WATER.—*L. Archbutt & M. Deeley, Derby.*—In carrying out this process the chemical reagents are, in the first instance, mixed with or dissolved in water in a small tank. This prepared solution is passed into a well in a large settling tank containing the water to be softened. Near the bottom of the well opposite a pipe projecting into the settling tank is fixed a trajector, for the purpose of creating a current through the well into the tank to mix the solution and water. To effect the rapid subsidence of the precipitate, perforated pipes are provided at the bottom of the settling tank, through which air is passed to stir up the old precipitate, as it is found that the two settle afterwards together more rapidly than a single slight precipitate. Claims: (1) In purifying water by precipitation mixing it with the precipitate of former operations; (2) the process of purifying water, consisting of introducing it into a vessel containing the precipitate of former operations, mixing it with any suitable precipitant, stirring up the old precipitate and mixing it with water, allowing the old and new precipitate to settle together, and drawing off the clear water; (3) the combination of a settling tank apparatus for mixing a precipitant with the water and apparatus for stirring up the old precipitate; (4) the combination of the settling tank, the trajector and perforated pipes, with or without the tank for the solution of reagents as described; (5) apparatus for softening and clarifying water substantially as described.—No. 1791. February 1st, 1889. 8*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

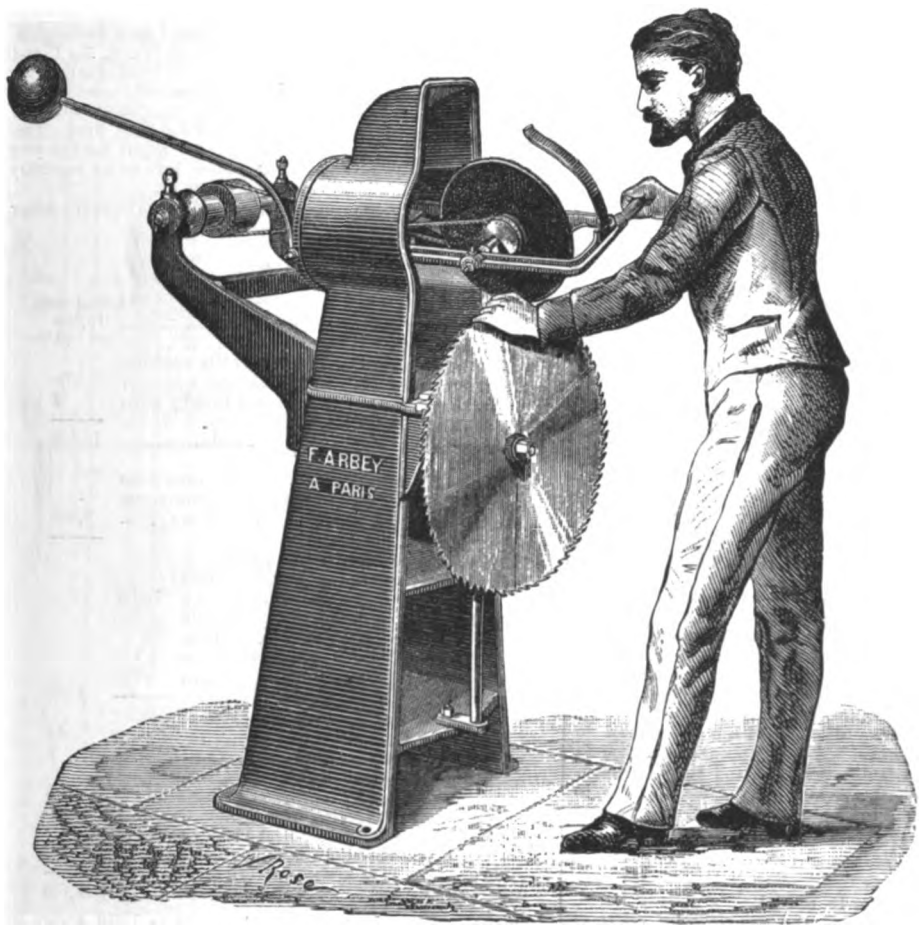

FIG. 1.—MACHINE FOR SHARPENING CIRCULAR SAWS.

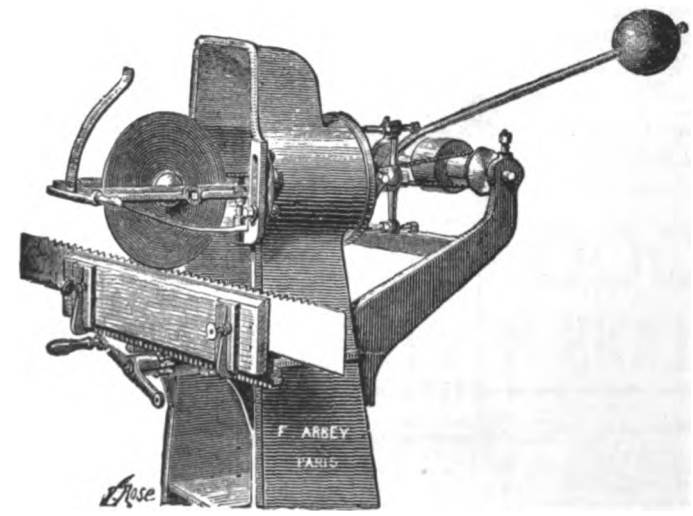

FIG. 2.—MACHINE FOR SHARPENING STRAIGHT SAWS.

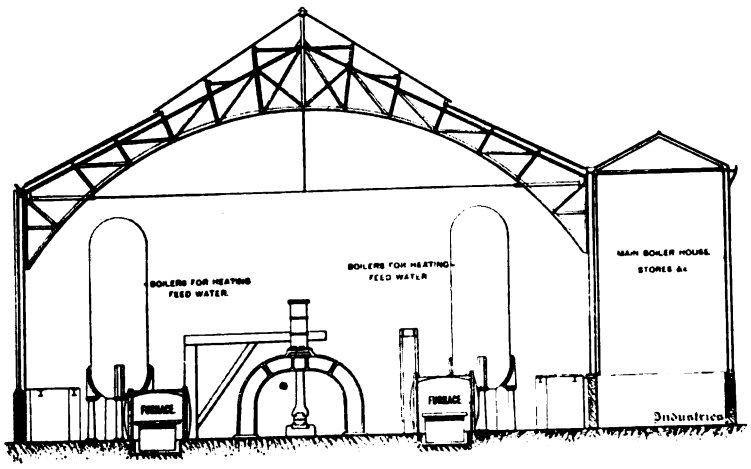
MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

WE illustrate above and on page 108 a number of special wood working and allied tools which were shown at the late Paris Exhibition by Messrs. Arbey & Son, of Paris. The most important machine shown in the agricultural department was a vertical saw with one blade at the side, which was intended chiefly for sawing thin boards and heavy planks out of logs. The saw is of great depth, and can be kept in high tension and made to work with accuracy. The log is supported by a carriage, which runs on broad rails and is very steady. Hence extremely thin boards can be cut of uniform thickness. The carriage is driven by a rack and pinion through a worm and worm wheel, and this feeds the timber at the rate of 1m. 50cm. per minute. The saw has four teeth set in each direction alternately. There is a continuous feed, and the sharpening is very simple. To change the saw only two bolts have to be loosed, and another frame with the saw adjusted can be bolted on, so that the old saw is being sharpened while the new one is working, without loss of time. The machine shown is for logs 1 metre in diameter, and it can cut stripe of less than 1mm. thick. A similar machine shown in Figs. 5 and 6 on page 108 is intended to take in logs of 50cm. diameter.

Figs. 1 and 2 represent a saw-sharpening machine shown in the same section. Fig. 1 shows it as arranged for sharpening circular saws, and Fig. 2 shows the arrangement for sharpening straight saws. An emery wheel is mounted in a frame and driven by a band from behind. The frame is capable of motion about an axis so as to bring the wheel down to its work, and its movement in this direction is regulated by adjustable stops. The wheel is balanced by a weight so as to be more easily worked, and also to be kept up clear from the saw when not pressed down. The wheel is also capable of motion about an axis perpendicular to the driving shaft, which enables it to be set at different angles for the teeth of different saws.

Figs. 3 and 4 on page 108 show a portable circular saw for sawing logs up to 60cm. diameter. In the figures the machine is fixed ready for working. The machine can easily be mounted on wheels and packed, so as to be carried to some other place where it is required. An engine of 8 h.p. is required to drive this machine.

A NEW FORGE AT WEST HARTLEPOOL.



AN important addition has recently been made to the Central Marine Engineering Works, West Hartlepool, in the shape of a new forge department. As it is exceptionally well arranged for carrying on the work, we paid a visit to the works, and by the courtesy of Messrs. W. Gray & Co. we are enabled to illustrate and describe the arrangements and plant. The whole of the arrangements have been carried out according to the designs of the manager, Mr. Thomas Mudd. The new forge in reality is a combination of forges, smiths' shop, and fitting and finishing shops, and is provided with all the requisite plant and machinery required in manufacturing any kind of forgings up to twenty tons in weight.

On page 99 is shown a ground plan of the new forge. As the building is long as compared with its breadth we have divided the plan into two parts and placed one underneath the other. It will be seen that A B are related to A^1 B^1. The new shop is 500ft. in length and 85ft. broad, and has a continuation shed of 32ft. span extending nearly the full width. The shed is open at the end, and beyond it there are five large water tanks for storing rain water, which is used for feeding the boilers. The shed has a 10-ton overhead travelling crane for lifting finished forgings from the bogies and placing them on the railway waggons. The lines of rails are both the ordinary gauge and 30in. gauge. In the yard, beyond the water tanks, are scrap shearing machines. A powerful one, recently constructed by Messrs. Rusworth & Co., of Sowerby Bridge, which can cut at one stroke 16in. by 1½in., with 34in. blades, is driven by an independent 12in. engine fitted with heavy double gearing. A large scrap cleaner of the churn type is also actuated by this engine. On page 98 is a cross section, from which it will be seen the roof is lofty. It is 60ft. high at the pitch, 36ft. at the eaves, and is supported by lattice girders, which are carried on columns formed of two cast iron girders united by straps. One end of the large building is built up, and it will be seen the main driving engine is placed here. The engine is of the ordinary horizontal non-condensing type, with a single cylinder, 16in. diameter, 36in. stroke. One of the fans is a 5ft. Schiele, and the other a 4ft. 6in. Powis, James, & Co.'s fan. Down one side there are twelve smiths' fires and three 1cwt. steam hammers. Then comes the stamping plant and a 12cwt. square-legged steam hammer with circular fire furnace and cranes for rudder frame and similar work, also a 20cwt. steam hammer flanked on each side with a furnace for ordinary forging purposes. This duplication feature is important and worthy of special notice. Adjacent to the 20cwt. hammer is the plant for completing forgings of unwieldy dimensions—*e.g.*, stern and rudder frames—and consists of a Davis & Primrose steam hammer, 16in. cylinder, 5ft. 6in. stroke; the main framing of this plant is placed on a girder of 37ft. span, and elevated about 9ft. above the ground. There are also two 15-ton steam and two 2-ton hand cranes, and two fires for this special work. Four furnaces are placed at suitable positions in connection with each of the two largest steam hammers, which are a 5-ton Rigby's patent, 30in. cylinder, 6ft. stroke, by Messrs. Glen & Ross, Glasgow, and a 7-ton Morrison's patent, 32in. cylinder, 7ft. stroke. Two furnaces are similarly placed to serve each of 40cwt. hammers, which are by Messrs. Glen & Ross and Messrs. Davis & Primrose, Leith. All the steam hammers have specially good efficiency owing to the high pressure of steam used in working them—viz., 100lb. per square inch. The two larger hammers are provided each with four 15-ton jib cranes, six of which are steam and two of hydraulic power, working at 1,250lb. pressure per square inch. Each of the 40cwt. hammers has two cranes—viz., two 2-ton hand, one 3-ton and one 5-ton, both hydraulic. The arrangement of the furnaces obviates the necessity of Sunday work or the stoppage of ordinary operations for their overhauling or repairing. Another important feature is the utilisation of the waste gases from the principal furnaces. From the illustrations it will be seen that in close contiguity to twelve furnaces there is a separate boiler or feed-water heater, in which the water is heated by the waste gases to a high temperature. Eight of these feed-heaters are 27ft. by 8ft. 6in., and four 21ft. by 7ft. 6in. The heated water is pumped into the main boilers by a Worthington pump, situated near the hydraulic pumps and accumulator. As already indicated, there are a large number of fitting and finishing tools for completing forgings. These are situated opposite the smiths' shop, and for carrying the work to the various tools there are two overhead travelling cranes—viz., one 10-ton driven by cotton rope, and a 7-ton driven by a square shaft from the main engine. Amongst the tools are two heavy slotting machines, respectively by Messrs. Sharp, Stewart, & Co., and Messrs. Scriven & Holdsworth; two shaping machines for preparing scarfs; two lathes, each capable of taking in work 22ft. long, the larger one, having 26in. centres, being by Messrs. Butterfield & Co., Keighley, and the 16in. lathe by Messrs. Dron & Lawson, of Dundee. Amongst the drilling machines are a multiple with twenty-eight drills, and another with four tools on two saddles, by Messrs. Joshua Buckton & Co., Leeds. A boring machine by Messrs. Noble & Lund has a 28ft. 6in. table and 24ft. stroke. The foundations are being prepared for a large planing machine 20ft. in length, 7ft. 6in. wide, 6ft. high, having a table divided lengthwise, so that the machine can be worked either as one or two. It has been constructed by Messrs. Spencer & Son, Hollinwood, near Manchester, to Mr. Mudd's designs. Amongst other tools are Ryder's forge for small work, a circular cold saw, boring machine, &c. It can readily be seen how advantageous are the general arrangements of this forge department for dealing with repairing and other work requiring great expedition.

A NEW FORGE AT WEST HARTLEPOOL.

(For description see previous page.)

TRANSVERSE SECTION.

THE MANCHESTER ASSOCIATION OF ENGINEERS.

AT a meeting of this society, held on the 25th inst., Mr. Michael Longridge read a paper on the "Evaporation in Lancashire Boilers," which we give in full as follows:—

The Lancashire boiler is such a common object in this part of the world that it is difficult to avoid the feeling that some sort of apology is required for venturing to ask a Society of Manchester Engineers to spend an evening in considering it, for it would almost seem as if everything that could be said about it must have been said already. In one sense this is true. As a structure the boiler has been so minutely studied and described that if the diameter and working pressure were given, none of us would find much difficulty in drawing a specification from which a perfectly safe boiler could be made, and if the factor of safety were also given I venture to say that, with the exception, perhaps, of some little disagreement about internal flues, the specifications would be practically identical. But if besides fulfilling conditions as to strength, the boiler were required to evaporate a given quantity of water in a given time and from a given quantity of coal, I fear that unanimity would vanish, that speculation rather than calculation would guide our pens, and that the result would be *quot homines tot sententiæ*. I at least have no hesitation in confessing that the problem would be very difficult to solve, and my object in bringing this paper before you is to explain how I have tried to solve it, and to learn what you have done in similar cases.

In 1882 a lecture was given at the Institution of Civil Engineers in London, by Mr. William Anderson, "On the Generation of Steam and the Thermodynamic Problems Involved." It is a lecture well worth reading, and it contains an illustration which I am sure Mr. Anderson will not object to my quoting, with one or two verbal alterations, as an introduction to my argument. He drew a picture (Fig. 4, page 101) representing the section of a hill-side. "Some distance up there is a lake L fed by streams running down from a still higher level. Lower down on the slope is a millpond P, the tail race from which falls into the sea. At the millpond is established a turbine, driven by water descending from the lake through a pipe. Datum or zero is the sea level. The level of the lake is T_o, and of the millpond T. W is the volume of water falling through the turbine per minute, σ the weight of one cubic foot. The sea level is the lowest level to which the water can possibly fall, hence its greatest potential energy, that of its position in the lake, is $W\sigma T_o$. The water is working between the absolute levels T_o and T, hence the maximum effect to be expected is $W\sigma T_o (T_o - T)/T_o = W\sigma (T_o - T)$." If for "hillside" we substitute "boiler flue," for "lake" "furnace," for $W\sigma$ the weight multiplied by the specific heat, or the heat capacity of the gases in the furnace, for T_o and T the absolute temperatures of the gases in the furnace and at the end of the flue, and for the sea level, the zero of absolute temperature, then $W\sigma T_o$ will represent the absolute energy of the heat generated in the furnace, and $W\sigma T_o (T_o - T)/T_o = W\sigma (T_o - T)$ the maximum proportion of $W\sigma T_o$, which we can by any possibility utilise so long as the initial and final temperatures of the gases are T_o and T. The proportion $(T_o - T)/T_o$ will no doubt be recognised as the Carnot's coefficient of efficiency of a perfect heat engine, and the illustration shows that we can no more utilise all the energy of the heat supplied to a steam boiler than we can all the energy of the heat supplied to any other heat engine; for we can neither make the temperature in the furnace infinitely great, nor that at the end of the flue absolutely zero. Thus, as the water in the lake possesses energy in virtue of its height, so does the fuel in the furnace possess energy in virtue of its temperature. As on the hill-side the energy of the water in the lake cannot become active without a fall of level, so in the boiler the energy of the heat in the furnace cannot be utilised without a fall in temperature. And as in the waterfall the work done by the turbine is proportional to the change of level, so in the heat engine is the work done by the heating surface proportional to the change of temperature.

Therefore if W be the weight of gases per lb. of coal, σ their mean specific heat at constant pressure, T_o and T the initial and final temperatures of the gases (whether measured from absolute zero or any other point is immaterial), the heat available for evaporating water cannot exceed $W\sigma (T_o - T)$ thermal units per lb. of coal.

So far we have dealt exclusively with quantity. We must now consider time, or settle the rate at which the heat $W\sigma (T_o - T)$ can be transferred from the gases to the water. This is really the question with which this paper is concerned, and it is a question of very considerable difficulty, and in my opinion well worth your consideration. The way in which I have tried to answer it is this: First, to obtain a general approximate formula connecting the different variables involved, and then to determine by experiment the constants and corrections required to make the formula available for numerical calculation under practical conditions.

If S = the number of square feet of heating surface per lb. of coal burnt per hour.
W = the weight of gases per lb. of coal.
σ = the mean specific heat of the gases under constant pressure.
T_o = the temperature of the gases in the furnace.
T = the temperature after passing over surface S.
t = the temperature of the water in the boiler.
m = the number of units of heat transmitted through the plates per square foot of surface per hour, and per degree difference of temperature.

Then considering m as constant and the rate of transmission proportional to the difference of temperature, the heat transmitted by an element of surface δS is $m (T - t) \delta S$: and the heat lost by the gases in passing over the surface δS is $-W\sigma\delta T$. Equating these two quantities we have $m (T - t) \delta S = -W\sigma\delta T$, or $-m\delta S/W\sigma = \delta T/(T - t)$ and integrating $-mS/W\sigma = \log_e (T - t) +$ constant, when $T = T_o$, $S = 0$. $\therefore 0 = \log_e (T_o - t) \times$ constant and constant $= -\log_e (T_o - t)$ whence $-mS/W\sigma = \log_e (T - t) - \log_e (T_o - t)$ or taking common logarithms and transposing $m = 2{\cdot}3 + W\sigma \{\log. (T_o - t) - \log. (T - t)\}/S$ (1) By means of this equation and a sufficient number of experimental observations of the values of the symbols in the right hand member, I hoped to determine the general value of the constant m, and this once done to use the formula

$\log. (T - t) = \log. (T_o - t) - mS/2{\cdot}3\, W\sigma$ (2) to calculate the final temperature T of the gases for any proposed case where the working conditions defining $W\sigma$, T_o and t were given, and then to calculate the probable evaporation in the following way:—

Having found T the heat lost by the gases is $W\sigma (T_o - T)$. Part of this heat is expended by transmission through the rickwork and by radiation, and partly in heating air drawn into the flues between the brickwork and the boiler. Call this heat R. The remainder is transmitted to the water in the boiler. If t_o be the temperature of the feed, w the number of lbs. of water evaporated per lb. of coal, then the heat transmitted to the water is $w (1114 + {\cdot}305t - t_o)$ thermal units per lb. of coal. Equating this to $W\sigma (T_o - T) - R$, the number of lbs. of water evaporated per lb. of coal will be $w = \{W\sigma (T_o - T) - R\}/(1114 + {\cdot}305t - t_o)$. (3)

It will be noticed that in constructing the general equation of transmission (2) I have treated m and t as constant, and have assumed that all the gas passes over the whole of the heating surface.

Now as regards m this treatment is certainly incorrect. Instead of being constant m is a function of T_o, T, t, of the condition of the plates in respect of soot and scale, and of the rapidity of circulation of the water and gas currents, for both water and gas are such bad conductors that unless the layers of heated water and cooled gas next the plates are rapidly displaced, the transmission is materially reduced. The mathematical expression of this function and its introduction into the differential equation, however, seemed so utterly impracticable, that there was no alternative but to adopt Newton's hypothesis, and treat m as constant in the integration, afterwards providing for such variations of this constant as experiment might suggest by a table of values or an empirical formula.

As regards t, the difference in the temperature of the water in contact with the different parts of the heating surface of Lancashire boilers is so small, that no material error can occur in treating it as constant and equal to that due to the steam pressure.

The error involved in the third assumption is also small, and the variation of the error smaller still, and it is this variation only which affects the coefficient m so long as this coefficient is applied to one type of boiler. Strictly speaking, the evaporation from the furnace plates should be calculated separately, and the formula (2) applied only to the part of the boiler beyond the bridge. But with any ordinary extent of heating surface, the results of the two methods differ by so little, that it is not worth while complicating the subject by the addition of another calculation.

Having made these necessary observations, I must now explain the way in which I have found the values of $W\sigma$, S, T_o, T, and t, which are required in order to determine m from equation (2), and I think I can do this best by taking a concrete case; for this purpose I have selected one of my own experiments with two Lancashire boilers, 7ft. diameter by 30ft. long, hand fired. This experiment is fully described in my annual report for the year 1888, and I will only give such particulars here as are necessary to the comprehension of the question before us.

The results of the experiment expressed in the form of a debtor and creditor account were as follows:—

BOILERS.

Dr.		Thermal units.
To calorific value of 1lb. dry coal		13,363
To heat contained in 1lb. coal		22
To heat contained in air, 14·79lb. entering furnace at 54°		179
To heat contained in moisture held by air		2
Total		13,566
Cr.		
By heat required to raise 9 819lb. water from 206° to 326°, and to evaporate it into steam containing 8 per cent. of moisture		9,626
Heat carried off in waste gases:		
9·146lb. products of combustion at 648°	1,606	
5·618lb. unburnt air, 0·135lb. vapour and 0·16lb. steam, arising from evaporation of water	914	
		2,520
Heat absorbed in evaporating ·016lb. water mixed with coal		18
Heat lost by imperfect combustion		0
Calorific value of ·0395lb. of unburnt carbon in ashes		575
Heat lost in clearing fires		45
Remainder, including heat lost by radiation and unaccounted for		782
Total		13,665

The heating surface of the boilers was 1,810 square feet, excluding the lower halves of the furnaces below the bars as is usually done, though why they should be excluded I do not quite understand, as they certainly receive heat radiated from the grates, though no doubt the quantity is very small.

The weight of dry coal burnt per hour was 1,073lb.

The weights, specific heats, and heat capacities of the waste gases are given below:—

		W lbs.	σ specific heat.	$W\sigma$ = Heat capacity.
Products of combustion	Carbonic acid	2·721	× 0·216	= 0·588
	Nitrogen	6·870	× 0·244	= 1·676
	Steam from combustion of hydrogen	0·445	× 0·481	= 0·214
				2·478
Air in excess and water	Air	5·618	× 0·238	= 1·337
	Vapour in air	0·135	× 0·481	= 0·065
	Steam from water mixed with coal	0·016	× 0·481	= 0·008
				1·410
				3·888

The value of S is found by dividing the heating surface by the weight of dry coal burnt per hour, and is in this case 1·69.

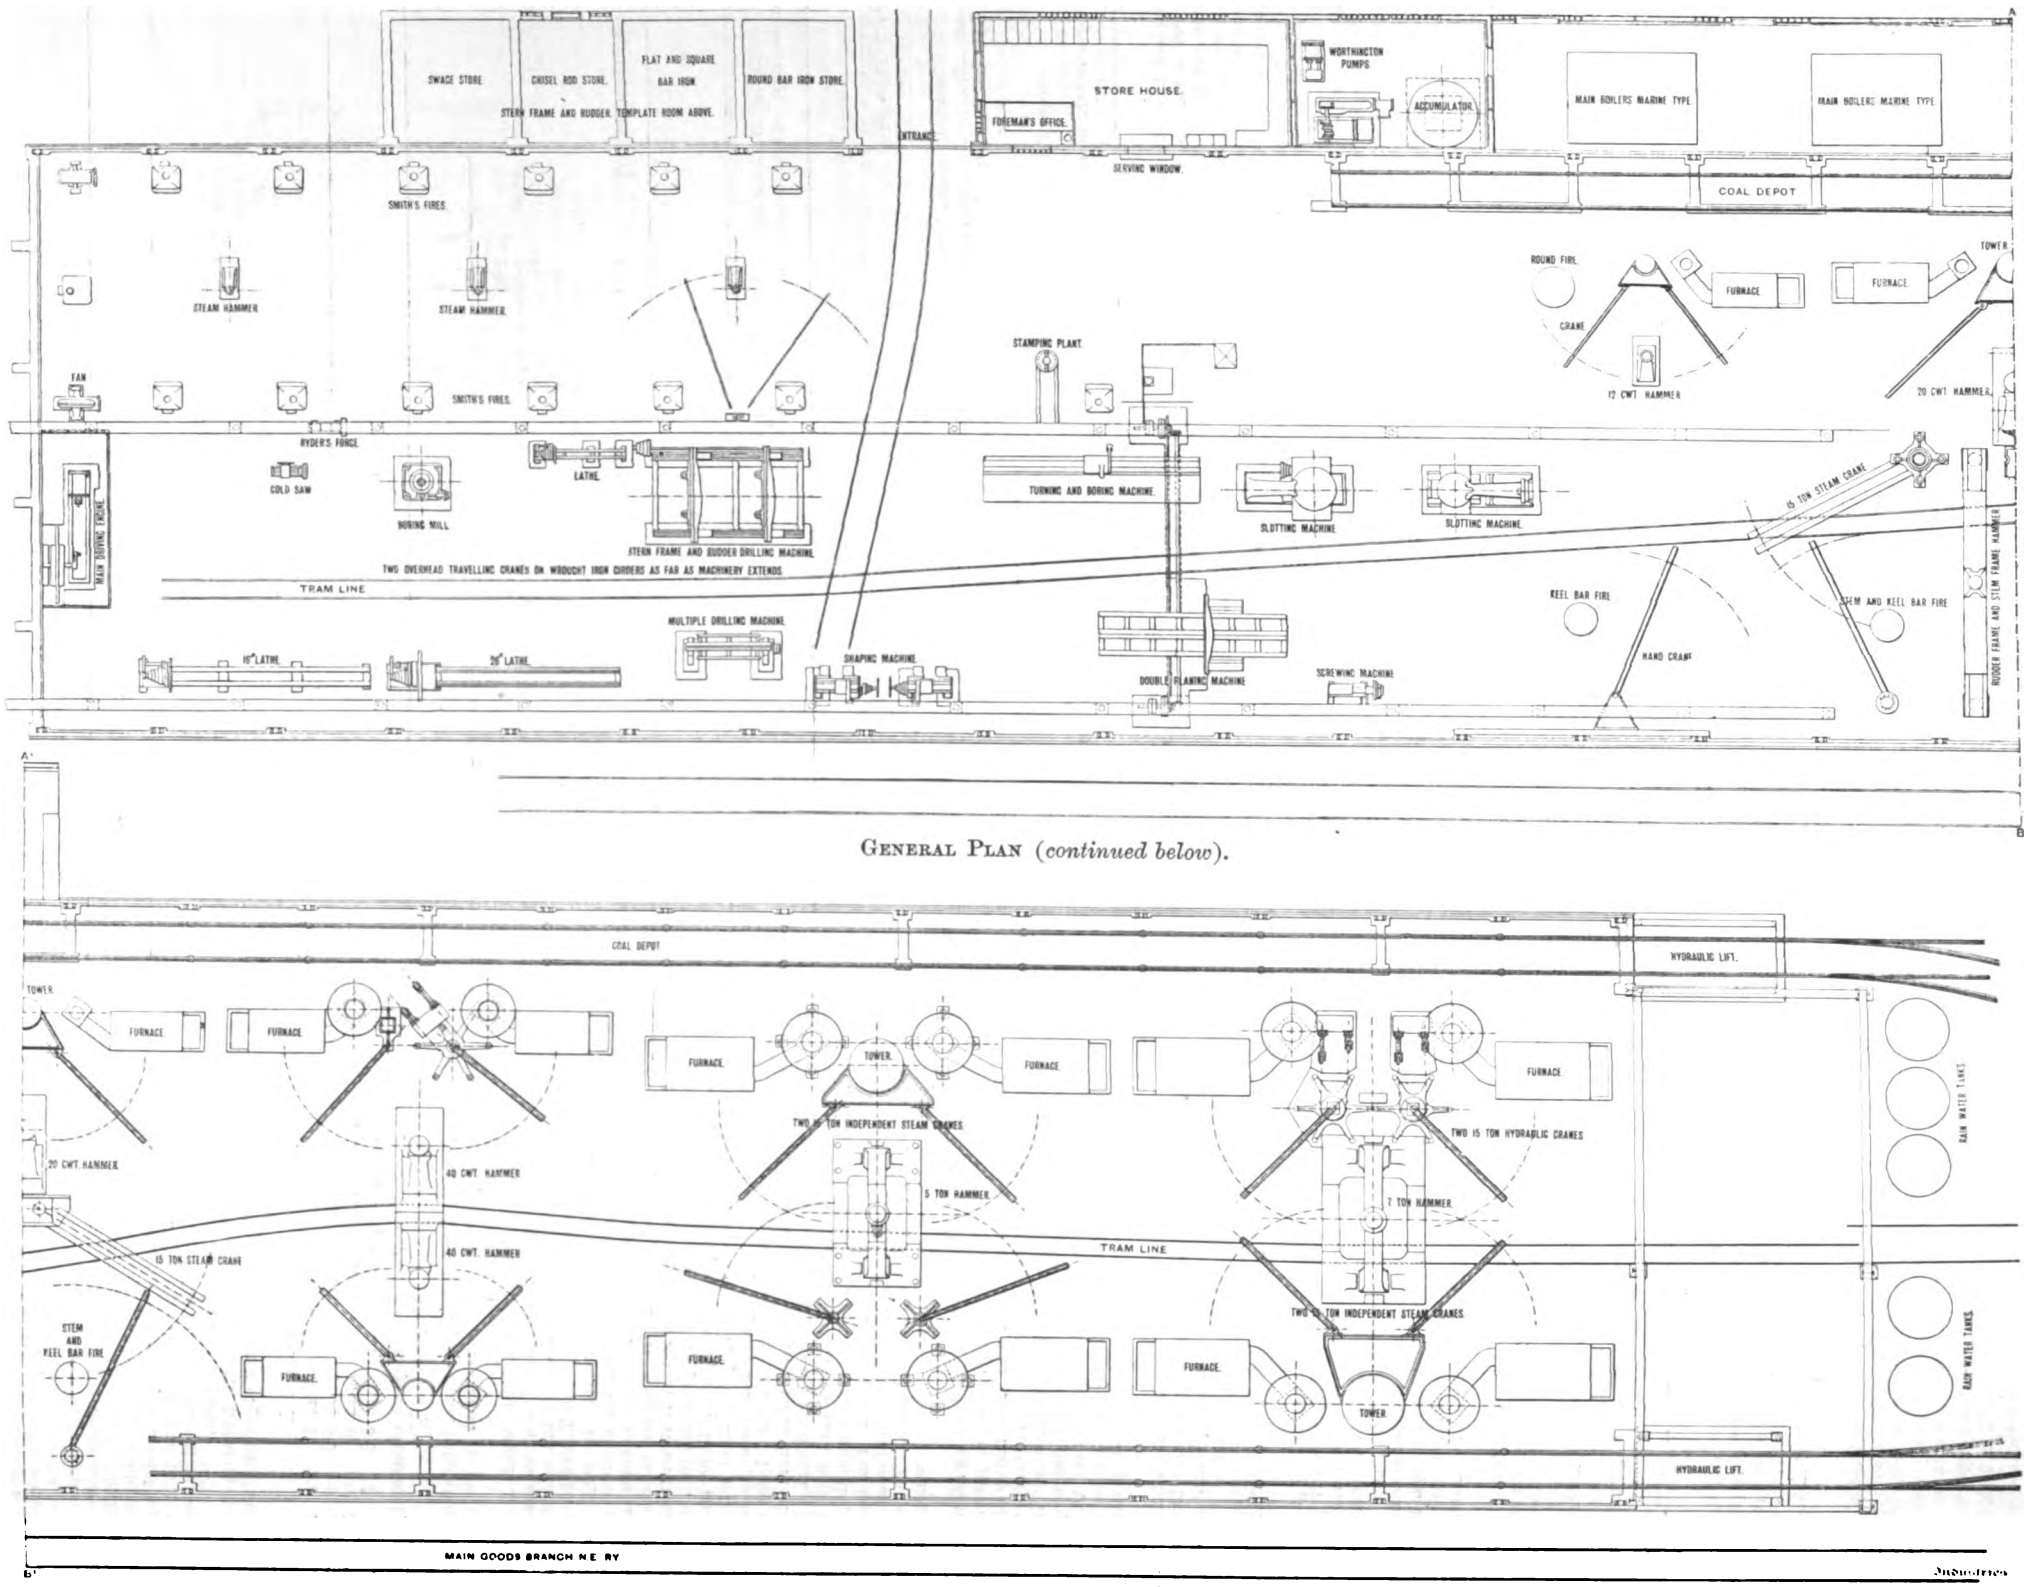
The value of $W\sigma$ is given above, namely 3·888.

The value of T_o must be obtained by calculation, since we have no reliable method of observing it directly. The calorific value of the coal was 13,363 thermal units, but this value was reduced by various losses in the furnace, as shown in the balance sheet, namely:—

18 units obsorbed in evaporating the water mixed with the coal.
575 units, the equivalent of ·0395lb. of unburnt carbon mixed with the ashes.
45 units lost in the hot ashes and clinkers, altogether 638 units, which being deducted from the calorific value of the coal leaves 12,725 units available for raising the temperature of the gases.

The heat capacity of the gases being 3·888, these 12,725 units will heat the gases $12{,}725 \div 3{\cdot}888 = 3273°$, and as the temperature of the air entering the furnaces was 54°, the temperature of the fire was 3327°, and this I take as the value of T_o.

The values of T and t were obtained directly by observation; they were 648° and 326° respectively.



Substituting these numbers in the right hand member of equation (2), we have $m = 2{\cdot}3 \times (3{\cdot}888/1{\cdot}69) \{\log. (3273 - 326) - \log. (648 - 326)\} = 5{\cdot}13$ thermal units.

From this slight sketch, you will see that the determination of m depends upon a knowledge of a number of other quantities, the accurate evaluation of some of which is very difficult. To begin with, it is by no means easy to learn the calorific value of the coal itself. First, there is the exceeding difficulty of selecting an average sample for analysis and testing, and, secondly, the calorific values calculated from analyses, hardly ever agrees with those found from calorimetric tests. In my work I have been forced to content myself with one analysis of each coal I have used, but when using the same coal for several days I have made generally three calorimetric tests for each day: unfortunately, I have found that the three tests of one day, though agreeing among themselves, have not in general agreed with those of other days, although the coal was

said to be supplied from the same seam and pit. I have found as much as 1,000 thermal units difference in different loads of what was supposed to be the same coal. In general I have taken the analysis (as was necessary) as the basis for calculating the volumes and weights of the chimney gases, but have relied upon the calorimetric tests for fixing the calorific value of the fuel. (Perhaps I may here suggest that in making tests with Thompson's calorimeter, the value obtained must be reduced by the heat liberated by the condensation of the steam arising from the combustion of the hydrogen in the coal, for when the coal is burnt in a boiler furnace this steam is not condensed, and does not give up its latent heat as it does to the water in the calorimeter. This correction is frequently overlooked; with Lancashire coals it generally lies between 400 and 500 units.) Secondly, there is the difficulty of determining the amount of the losses in the furnace, which have to be deducted from the calorific value of the coal, before the quantity of heat available for the calculation of T_o can be fixed. The most important of these are—the heat equivalents of the unburnt carbon, which is lost among the ashes, and of combustible gases, passing off unburnt. Without making an analysis of the ashes, which I have been unable to undertake, the only means of estimating the quantity of unburnt carbon is to deduct the percentage of ash given by the coal analysis from the percentage actually thrown away; a method which can only give correct results if the percentage given by the analysis of the single sample analysed be the same as the percentage in the bulk of the coal burnt. The amount of the loss due to imperfect combustion is also difficult to ascertain outside a laboratory. It is frequently asserted that combustible gases cannot exist in company with a large excess of air. This I think is a mistake. It is true it is often difficult to find carbonic oxide, while carbon vapour and free hydrogen entirely elude the snares of the apparatus ordinarily used for outdoor work. My experience, however, is, that with care and patience carbonic oxide can very frequently be found in small proportions, while as regards free hydrogen the experiments of Scheurer Kestner* seem to show that, in general, about 20 per cent. of the hydrogen in coal escapes unburnt whether the supply of air be great or small.

If these experiments be relied on, the losses in the furnace will exceed those found in the balance sheets of trials, while the remainders usually ascribed to radiation and heat unaccounted for will be diminished. Hence the probability is that the losses in the furnace have been under-valued, and the temperature T_o over-stated somewhat in my experiments.

Lastly, there is great uncertainty about the temperature of the waste gases if they exceed 600°, the maximum temperature for which a mercury thermometer can be used. I have tried Casartelli's, Schaeffer's, and Murrie's pyrometers, and found them altogether unreliable; hence in all the experiments in Table I., except those lettered A to E, I have had to correct the observed final temperature of the gases. This I have done by assuming a loss of 700 units from radiation and communication of heat to air drawn into the flues between the boiler and the brick-work, adding this to the heat absorbed by the water, and dividing the sum by the heat capacity of the gases, and then checking the results by the work done in the economisers, and the heat carried up the chimney where the temperatures were measurable by a mercury thermometer, and though I cannot hope to have arrived at accurate results, I think the figures are not far from the truth.

In experiments D and E, the pyrometer was found to agree with a mercury thermometer up to 550°, and therefore the observed temperatures of the waste gases are probably not far wrong, and are given as they were observed. Experiment B was made in Vienna, and I have no information about the pyrometer used. In experiment A the final temperature was low enough to be measured by a thermometer. The temperatures in Table II. were all taken with a thermometer and are correct, except perhaps those in L and M.

With such difficulties to overcome, it is not surprising that the determinations of m which I have hitherto made should be somewhat variable. They are given in Tables I. and II., and cannot be considered as more than near approximations.

The figures in Table I. refer to Lancashire boilers, those in Table II. to a combination of a Cornish boiler with a pipular boiler; but inasmuch as the furnace was internal, and the greater part of the evaporation done in the Cornish part, I think the values of m obtained from it are worth producing in addition to those shown in Table I.

Referring to these tables you will see that in experiment A the value of m is very low; the reason, I think, is that the temperature of the gases was reduced so much as to deposit a great quantity of soot upon the latter end of the large heating surface, and thus the effective heating surface per lb. of coal burnt was really less than the value ascribed to S. If this ineffective surface were not counted, the value of S would be reduced and that of m increased.

In C also m has a low value, but this is fully accounted for by the fact that the boilers were old ones, fed with very dirty water, and coated internally with thick scale. The figures in column D were obtained from the same two boilers as those in column E, and it is likely that the different values of m in the two experiments is due to the different conditions under which the boilers worked. The difference between T_o and the observed value of T being produced in part by the absorption of heat by air entering the flues between the boiler and the brickwork, it is natural that T should be lower with the strong draught, like that indicated by the value of W σ in D, than with the weak draught shown in E. But the formula for calculating m is based on the supposition that the difference T_o – T is produced by absorption of heat by the water alone, hence the value of m determined by it will always be higher with a strong draught or leaky flue than with a weak one and air-tight flues, and the actual coefficient of transmission rather less than the calculated. The high coefficients in F, G, H, I, J are due partly to strong draught, and partly to the boilers being very clean. The high values in L and M are inexplicable, except on the supposition that the thermometer was affected by a current of cold air, which entered at the damper-hole and at a crack in the brick-work, or that the loss by imperfect combustion was greater than that calculated from my analysis of the gases, or that the net heating value of the coal and the temperature T_o were over-estimated. The last seems the most likely, for the coal had been lying out of doors some time, and the outside of the heap was used for trial L, and the part near the outside for trial M. The low values in P – U are no doubt due, as in A, to the effective surface of the boiler being less than the actual surface, owing to deposition of soot upon the hinder parts.

On the whole I am disposed to think that the following values of m may be adopted till further experience throws more light upon the subject:—

TABLE III.

	S = 1	1·5	2	3	4
For very clean boilers.....	m = 6·5	5·9	5·5	4·9	4·6
For fairly clean boilers	m = 6	5·4	5·1	4·6	4·3
For rather dirty boilers	m = 5·5	4·9	4·6	4·2	4·1

Intermediate values of m may be obtained by the formula

$$m_n = m_1 / \sqrt[4]{S}.$$

Of course this formula has no rational foundation; it is only a convenient expression for substitution in the general formula when S is the unknown quantity.

I now return to the problem with which I started, namely, that of designing a Lancashire boiler to evaporate a given quantity of water at a given rate. If the calorific value of the coal and the value of W σ be given, T_o can be calculated and T found, and this once done, the rest is easy. But as these quantities are generally unknown, the engineer will have to fix them arbitrarily, and therefore ought to know the limits within which they usually lie. As regards the calorific value of Lancashire coals, my experience is that it varies from 12,000 units to 14,000 units, and that ordinary good mill coal, whether slack or burgy, has generally a value of about 13,500 units, and contains according to analysis about 78 per cent. of carbon and between 4 and 5 per cent. of hydrogen. The losses in the furnace may usually be taken between 500 units and 1,000 units per lb. of coal, thus reducing the calorific value from which T_o must be calculated to about 12,750 units for good coal. These losses are generally rather greater with slack than with burgy, owing to mechanical difficulties; for the same reason they are likely to be greater with bad coal than with good. For instance, with coal worth only 12,000 units, the value in the furnace would probably not be more than 10,800 or 11,000 units. The value of W σ depends, of course, upon the weight of air which passes through the flues per lb. of coal.

It is generally assumed that 12½lb. of air are required to burn 1lb. of coal in theory, and about 18lb. in practice. But this is only true for carbon, not for coal. As a matter of fact, good Lancashire coals require about 10lb. of air in theory, and with careful stoking, about 15lb. to 16lb. of air in practice. In such cases the value of W σ will be about 4·5, but in designing a boiler it will be better to take W σ at 4·7 for good coal. Of course W σ can be increased to almost anything by having a roaring draught such as some firemen delight in. Several such instances are noticeable in Table I.

And lastly, as to R, the heat lost by radiation and air leakage into the flues. Very few direct experiments have been made to determine R. It is generally found by difference, and thus includes all errors of observation. As far as I can judge with single Lancashire boilers, R ought to be between 1,000 and 700 units, and with groups of boilers between 700 and 400 units, per lb. of coal.

We can now proceed to the solution of our problem. Suppose it be required to evaporate 5000lb. of water per hour under a pressure of 100lb. per square inch (115lb. absolute) from feed water at 100°, and at the rate of 9lb. of water per lb. of coal. The heat required to evaporate 1lb. of water under these conditions is 1114 + ·305 × 338—100 = 1117 thermal units; therefore the heat transmitted through the plates from each lb. of coal burnt must be 9 × 1117 = 10,053 thermal units, to which must be added, say, 700 units for radiation, &c., making in all 10,753 thermal units.

Assuming the coal to have a calorific value of 13,500 units, or 12,750 units after deducting losses in the furnaces, the air to be at 60° and the value of W σ to be 4·7, then the value of T_o will be 12750/4·7 + 60 = 2770, and that of T is given by (3), viz., 4·7 (2770—T) = 10053 + 700, whence T = 482°.

What heating surface is required to reduce the temperature of the gases to 482°? The answer is given by equation (2), viz.:—

$$S = 2{\cdot}3\ W\sigma \left\{ \log.(T_o - t) - \log.(T - t) \right\} / m$$

Taking the value of m from the second line of Table III., referring to fairly clean boilers—viz., 6 / $\sqrt[4]{S}$ and t = 338, the temperature of steam at 100lb. pressure, we have

$$S = 2{\cdot}3 \times \frac{4{\cdot}7}{6} \sqrt[4]{S} \left\{ \log. 2432 - \log. 144 \right\}$$

or $$S^{\frac{3}{4}} = 1{\cdot}8 \times (3{\cdot}38596 - 2{\cdot}15836) = 2{\cdot}2086$$

The fourth root of S^3 may be extracted with the aid of a table of squares and cubes, by taking the square root of 2·2086, then the square root of that square root, and finally the cube of the result, or more conveniently by a table of logarithms. Thus:—

$$\tfrac{3}{4} \log. S = \log. 2{\cdot}2086$$

or $$\log. S = \tfrac{4}{3} \times 0{\cdot}34312 = 0{\cdot}45748$$

whence S = 2·87 sq. ft. per lb. of coal.

Now the coal to be burnt per hour is 5,000 / 9 = 556lb., therefore the heating surface required is 2·87 × 556 = 1,596 sq. ft.

How many boilers shall we use?

This depends upon the area of fire grate required. Well, my experience upon the point is this, that it is difficult to burn less than about 16lb., or more than about 21lb. of coal per sq. ft. of grate in Lancashire boilers, without considerable excess of air. Having to burn 556lb. of coal per hour, therefore, the total grate area should not be less than 26·5 sq. ft., or more than 33·5 sq. ft. Moreover, the length of each grate must not exceed 6ft., and

EVAPORATION IN LANCASHIRE BOILERS.

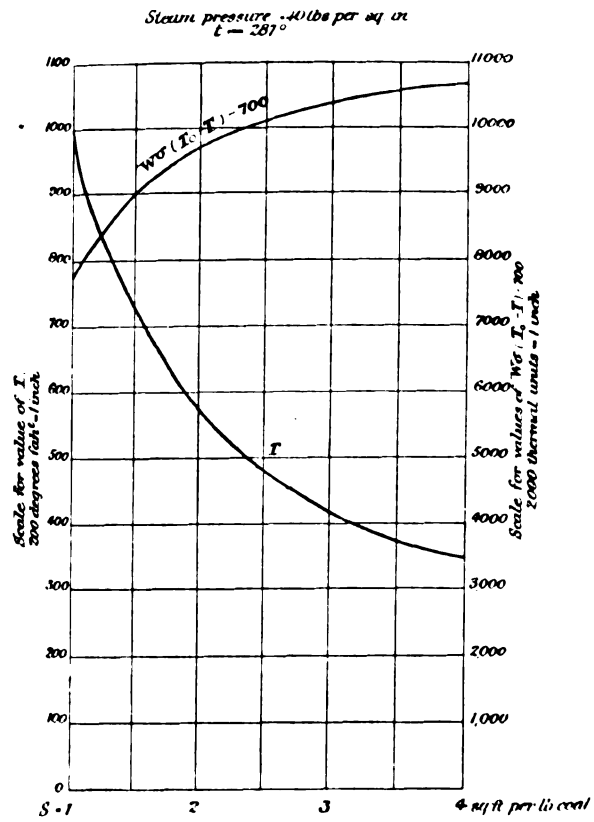

FIG. 1.

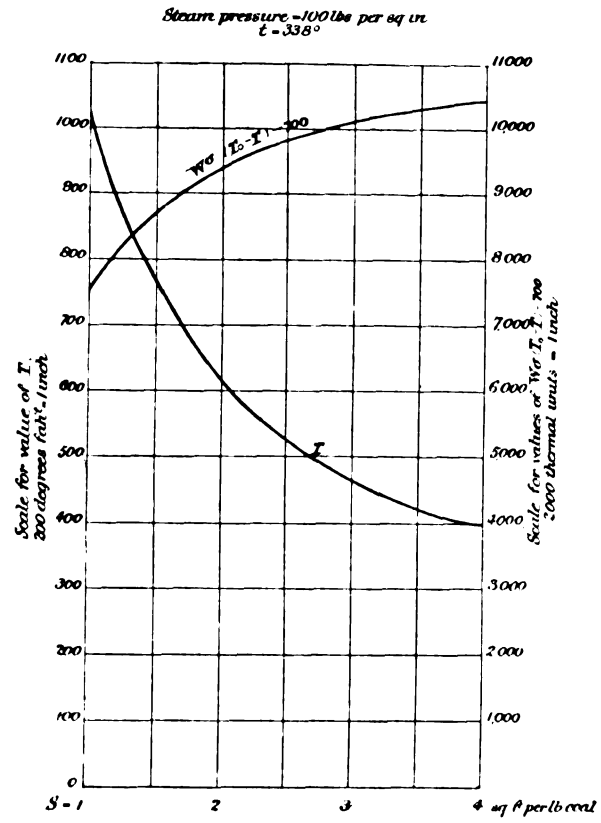

FIG. 2.

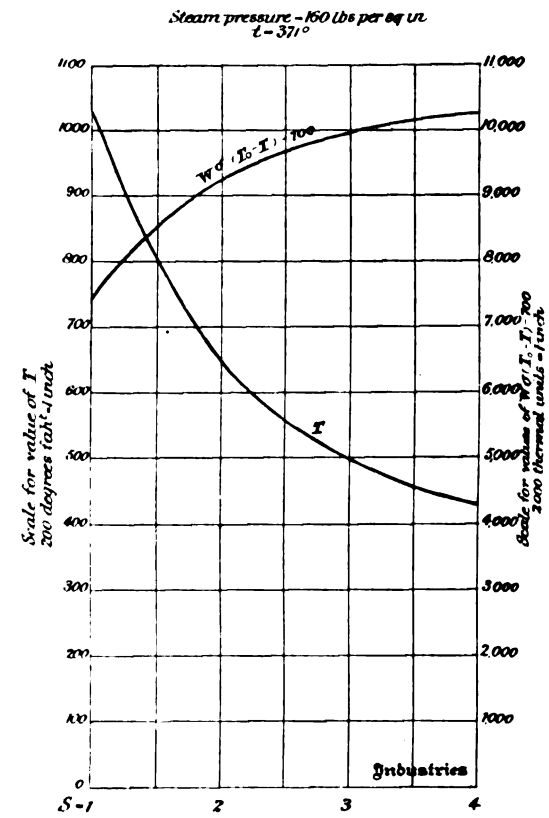

FIG. 3.

should not by preference be less than 3ft. 6in. The best way of fulfilling these conditions would probably be to have two Lancashire boilers, 7ft. diameter by 27ft. long, with internal flues 2ft. 8in. diameter, and grates 3ft. 6in. long, set low in the furnace, especially at the back ends, in order to reduce the mean width to about 2ft. 5in. In order to facilitate this kind of calculation I have drawn up Table IV. for pressures of 40lb., 100lb., and 160lb., giving the values of S, m, T, t, and $W\sigma(T_o - T) - 700$ (= the heat available for evaporation) on the assumption that—

The calorific value of the coal	=	13,500 thermal units.
The losses in the furnace	=	750 ,,
The heat available in the furnace	=	12,750 ,,
Loss by variation	=	700 ,,
The value of $W\sigma$	=	4·7
Temperature of air	=	60°

and from the figures I have plotted the three curves, Figs. 1, 2, and 3; the abscissæ being the values of S, and the ordinates the corresponding values of T, and of $W\sigma(T_o - T) - 700$.

I have now done my best for the engineer, and will conclude my paper with a few practical hints to boiler owners.

1st. Get your boilers designed for the work they have to do, and not made 7ft. 6in. × 30ft. or 8ft. × 28ft. as the case may be, because it is the fashion to have boilers of these particular dimensions.

2nd. Don't stick to 6ft. grates if a shorter length is required to burn the coal at the rate of from 16lb. to 21lb. per hour.

3rd. Reduce your draught as much as the nature of the coal and the smoke inspector will permit. Try and reduce it till the fire is hot enough to melt a piece of steel boiler plate.

4th. Buy your coal dry and keep it dry. Weigh the ashes which come out of the furnaces as well as the coal that goes into them.

5th. Be most careful to stop up air leaks in the brickwork and between the brickwork and the boiler.

6th. Establish a gasometer for collecting gases from the flues and analyse them for carbonic acid, and try to get 10 or 11 per cent. of that gas in the samples by cutting down the draught. The apparatus and its manipulation are of the simplest character, and the information gained will be of great practical utility, and will often lead to considerable economy.

In the discussion which followed the reading of the paper, Mr. Longridge explained that the table of coefficients did not pretend to be absolutely accurate, as the number of experiments were few. It was well known that the conductivity of metal was greater at a low than at a high temperature, and it might therefore be argued that it should be higher at the back than at the front of the boiler. But this reasoning left out the fact that the accuracy of the coefficient depended largely upon radiation, which was, of course, greatest at the furnace end. Again, the mobility of the water and gases was an important element, as both were bad conductors, and if they were in a state of rapid motion they aided the transmission of heat very materially. These conditions prevailed at the furnace ends, where not only was the water more agitated, but the volume and velocity of the gas were necessarily much greater than elsewhere.

Mr. Boswell agreed that engineers did not know as much about boilers as they thought they did. Fashion played an important part in the determination of the size of boilers ordered, and as a proof of this he might say that the boilers used in the Manchester Exhibition having been all 30ft. by 8ft., steam users for a long time afterwards would buy no other size. With reference to the formulæ used, he presumed they referred to the average quality of fuel, but it was known that cheaper coals were being used, and in some cases, with systems of forced draught, "duff" and such like fuel material was employed. The formulæ, therefore, would require amending. He was of opinion that what was wanted was to educate the stokers, and under present conditions the formulæ used would need to have a good margin where careless men were employed. Having given some instances of stupidity on the part of steam users, he said that, as in erecting a building an architect was called in, so in putting in a boiler a skilled maker should in every case be consulted.

Mr. Rea asked if Mr. Longridge meant to imply that a smaller boiler with a small grate was better than a larger one with a large grate. He would like some information as to the size of flues under and at the side of the boiler. In one system the former were made 6ft. high, the idea being to get a slow motion of the gases. What, he asked, was the best speed of gases through the different flues so as to get the greatest effect from radiation? He then referred to the cold zone theory of Mr. Thos. Fletcher, and asked what was the actual loss in transmission through the plates. Was there really much advantage in the corrugated flue or the Galloway tube from the point of view of economy? He thought there was a good deal of heat yet to be saved in boiler practice, and thought it was advisable to pay the stoker good wages in order to get a good man.

Some questions were then asked as to forced draught, and whether the efficiency of the boiler did not depend largely on the velocity of the gases, after which

Mr. Schofield asked for information as to the velocity of the draught. He questioned whether the bridge was of any value, and was inclined to the use of a furnace 8ft. long, in an ordinary sized boiler, but without bars for the last two feet, and without bridge, no air being admitted beyond that point. He did not agree with too great a reduction of the temperature of the gases on leaving the boilers. They should not be reduced below 500° F. To allow this heat to escape was, he thought, a mistake, and the use of an economiser appeared to him to be imperative for good working.

Mr. Longridge, in reply, said that his experiments were, of course, made with good coal, but the formulæ

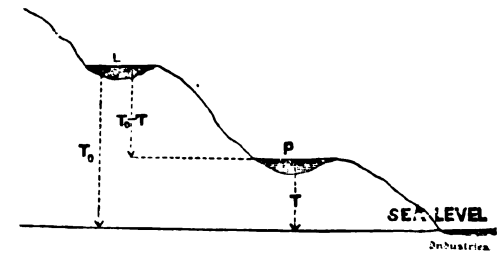

FIG. 4.

equally applied to all kinds of coal, as all that was necessary was to substitute the value of T_o, which could easily be calculated. He agreed with the French method of giving prizes to stokers at an annual competition, which would lead to improved stoking. The size of a boiler was, within certain limits, immaterial; the amount of heating surface determining the economy, and the size of the grate must largely depend on the class of coal used. For instance, Welsh coal being slow burning, and not easily moved about, was not so good to burn as Lancashire coal. It was difficult to fix the proper velocity of the gases, but he thought that an excess of air to the extent of 60 per cent. was the best condition to aim at. The quantity and speed of radiation was necessarily different under different conditions, and a Lancashire boiler being a slow-working machine could not fairly be compared with a locomotive boiler. He thought the Lancashire boiler was nearly perfect, and did not see how it could be much improved. The expression $W\sigma(T_o - T)$ represented the maximum transmission of heat, and was nearly reached. It was not possible to raise the value of T_o very much, as, if it was, dissociation took place. He had known this to occur at 1050° F., and 3 per cent. of carbon vapour to exist in boiler gases. Forced draught might be advantageous with thick fires and hard firing, and with the consequent resistance to the air. He did not think there was much gain in increasing the size of flues, as gas always follows the shortest course, and if the draught was not impeded the smaller the flues the better. The thickness of plates did not much matter, as the resistances occur when the heat was entering and leaving the plate, so that a variation in thickness would make an immaterial difference. Of course, with the extra thick plates about to be used for high pressure, there would be constructional difficulties which would require consideration. The best temperature of a furnace was the highest obtainable, one sufficient to melt a piece of steel being very effective. This could be obtained by a regulation of the draught.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE, PAGE 105.)

PARIS, 28TH JANUARY, 1890.

COAL.—The total imports of coal delivered for consumption in France in 1889 amounted to 7,800,249 tons, against 8,217,511 tons in 1888, a decline of 5 per cent. Of this loss of some 417,000 tons, 145,000 may be placed to English, 152,000 to Belgian, and 114,000 to German account. The coke imports also show a falling off, the total for 1889 amounting to 1,157,440 tons, against 1,186,913 tons in 1888. The falling off is in the trade with Germany, and it is much greater than the difference between these totals, the Belgian imports having increased considerably. The exports of French coal and coke in the year last past amounted to 1,682,527 tons, against 1,464,904 tons in 1888.

IRON.—The situation of the iron trade, now that we have fairly entered on the new year, is found to be satisfactory in an exceptional degree. In all districts manufacturers have their order books well filled, and fresh contracts, often of considerable importance, are being entered into daily. Engineering firms are very busy. Makers of railway rolling stock are overwhelmed with work. Besides the 3,000 goods waggons already contracted for for the Northern Railway, orders for 500 more are about to be placed, while still larger orders are in sight. Among locomotive builders, the Société de Construction de Batignolles and the Société Cail have each secured a contract for 30 powerful engines. In the shipbuilding yards the greatest activity prevails. Founders, too, are everywhere well supplied with work for the next six months. Here in Paris the market is calm, but firmer than it was a week ago. Old rails are quoted 88s. In the Haute Marne plates are in strong demand at 184s. common, and 208s. steel. The price of most articles of ironmongery has been advanced 10 per cent. In the Ardennes bars sell at 156s. and 160s. Tool steel is quoted 52s. per cwt. The declared value of the imports of iron of all sorts in 1889 is £254,360, against £358,120 in 1888, while the value of the exports has increased from £370,240 in 1888 to £907,320 in 1889.

LABOUR.—Paris is likely to be profoundly disturbed ere long by the labour movements. The Great Exhibition attracted large numbers of workmen of all classes to the capital, not only for the construction of the buildings in the Champs de Mars, but for the erection of numerous other structures which were pushed forward for completion last year. A large proportion of these have now no occupation, and there is much discontent and ferment in consequence. The Socialists are turning the opportunity to account to bring about a general strike in the spring. The prospect is contemplated with much anxiety in industrial circles.

SUBURBAN TELEPHONES IN PARIS.—The system of management of suburban telephone centres has hitherto been very vexatious. The details of the old system are, of course, only of local interest, but it may be said briefly that the chief objection lay in the high rate charged for the use of the trunk connecting line, in addition to the necessary subscriptions that had to be paid for the use of the two central offices at each end. These exorbitant charges have now been modified, and the suburban centres are formed into groups which can communicate with each other with less difficulty.

THE EIFFEL TOWER AS A LIGHTNING CONDUCTOR.—Some experiments have been made by electricians for the purpose of ascertaining what amount of protection will be afforded to the city of Paris by the Eiffel Tower. The conductivity of the tower is very great, of course, and the resistance of the "earths" are comparatively small, so that, if lightning conductors are any good at all, the Eiffel Tower ought to be of considerable value.

ELECTRICITY IN PARIS.—The commission of the Paris Municipal Council which has had the granting of licences for public electric installations has inserted a clause in the charters of agreement to the effect that all the machinery and plant used in the installations shall be made by French firms. It appears that all the electric pioneers are making use of the home-made article with the exception of the Popp Company, who are employing some English and American machines. This company, however, established its plant before the decree of the Council went forth.

BERLIN, 27TH JANUARY, 1890.

THE RAILWAYS IN 1889.—The report of the Minister of Public Works for the fiscal year 1888-89 shows a considerable extension of the Prussian railway system, and a notable development of the traffic in that period. The total length of the lines open at the end of the year was, exclusive of narrow gauge "feeders," 23,020 kilometres against 22,466 kilometres in the previous year. The total length of the private lines was 2,647 kilometres. The rolling stock is returned as consisting of 8,797 locomotives, of an estimated value of 393 million marks; 13,953 passenger carriages, valued at 118 millions; 3,791 goods vans, valued at 24 millions; and 174,428 goods waggons, valued at 500 millions. The increase in the passenger traffic was 8·4 per cent. relatively to the preceding year. Of this increase 53 per cent. occurred in the third-class traffic, 33 per cent. in the fourth-class, 10 per cent. in the second-class, and about 0·5 per cent. in the first-class. The increase in the receipts was 5·5 per cent. The goods traffic amounted to 108·4 million tons against 98·9 millions in the previous year, an increase of 9·6 per cent. To fully appreciate the significance of these figures, it is necessary to bear in mind that the goods traffic of 1887-88 showed a large increase over that of 1886-87.

SILESIAN COAL AT LÜBECK.—At a meeting of manufacturers held last week at Lübeck a resolution was passed to the effect that it is desirable, in the interests of the industries of the locality, to open up a trade in coal with Silesia in competition with English and Westphalian coal. By a reduction of the railway tariff from 185s. to 111s. a truck-load of 10 tons, Silesian coal could be sold at Lübeck, at present prices, for from 170s. to 180s., against 225s. for English and 210s. for Westphalian coal. As the Silesian coal is of a quality superior to that of either the English or Westphalian, a good trade could be established if such a reduction of the cost of carriage could be obtained as was recently conceded to the Westphalian importers.

ELECTRIC LIGHTING.—The use of the electric light has become general in the industrial districts of Upper Silesia. Nearly all the mines have their surface works lighted by arc lamps, to enable those engaged in the work of sorting, screening, and washing to carry on operations after dark. At Ruda the greater part of the village is included in the area lighted by the mine owners. Besides mining, the light is used largely in factories, workshops, and railway stations, and about buildings in course of construction. It cannot be doubted that the productive capacity of works is considerably augmented by electric lighting. The town of Hanover has just decided to adopt the electric light, and the council has voted a sum of £75,000 for the commencement of the scheme. The first order for an installation of 15,000 lamps has been given to Messrs. Schuckert.

TELEPHONIC COMMUNICATION WITH VIENNA.—The project for connecting Berlin with Vienna by a telephone line is receiving much attention. The preliminary experiments and tests have been made, and with such success that negotiations have been commenced between the two Governments with a view to an agreement for the immediate construction of the line. There can be no doubt that telephonic communication between these two capitals would tend greatly to promote the trade of both countries. A new form of receiver has recently been tried which makes, it is said, the voice of the speaker heard in any part of a large room.

THE BALTIC AND NORTH SEA CANAL.—At the end of last week the telegraphic communication between all the engineers' offices afong the line of the Baltic and North Sea Canal and the head office at Kiel was completed. The workmen's "barracks" are connected by telephone with the office of the engineer of the section in which they are situate, and also with the residences of the canal inspectors. The work of excavation proceeds apace. The contractor for the section situate between the town of Rendsburg and the Audorf lake had, at the end of 1889, removed 275,000 cubic metres, a quantity greater by 25,000 cubic metres than that to which he was bound by his contract.

MESSRS. IVAN LEVINSTEIN & CO., LD.—The German technical papers are much interested in the news about the formation of Mr. Levinstein's firm at Manchester into a limited company, for it appears that the proprietors of the Actiengesellschaft für Anilinfabrikation and the Farbenfabriken v. F. Bayer & Co., are among the shareholders in the new company. Mr. Levinstein has for a long time been the Germans' strongest rival, and the new departure is, therefore, not without interest.

THE WALCKER ACCUMULATOR COMPANY.—Some time ago mention was made in these columns of a new accumulator which was being placed on the market by M. Walcker. In this battery the plates were arranged as concentric cylinders, and many advantages were claimed for its use. The company which was started to exploit the invention has not met with success so far; it is even said, and it is not at all improbable, that the bank which had a mortgage on their works has taken possession.

THE POPP COMPRESSED AIR SYSTEM.—The savants and engineers at Berlin and Vienna have been merciless on the Popp system for the transmission of power by compressed air. A number of them have sent in reports to the *Allgemeine Electricitäts Gesellschaft* as to the comparative merits of electric and compressed air distribution of power, and it need hardly be said that they are all very much in favour of electricity. One professor stated that as much as 60 per cent. of the power was lost in the Popp distributing mains, which, although a very high figure, is probably not far from being correct.

CYCLE EXHIBITION.—On the 22nd prox. an Exhibition of cycles, &c., is to be held at Leipsic. Most of the leading makers in England, Holland, and Austria have applied for space, and the display of foreign articles will be far more extensive than in any previous exhibition of the sort.

THE NORDDEUTSCHE LLOYD.—During the past year the distance travelled by steamers belonging to this company were as given in the following official table:—

Bremen to New York	726,000	miles.
„ „ Baltimore	300,000	„
„ „ South America	550,000	„
„ „ East Asia	300,000	„
„ „ Australia	340,000	„
Hong Kong to Japan	44,000	„
Sydney to Samoa	65,000	„
Brindisi to Port Said	48,000	„

VIENNA, 27TH JANUARY, 1890.

COALS.—Everything is favourable for the improvement in the coal traffic. The advance in the rates for iron is causing a brisk activity in coal for rolling mill purposes, and the reopening of the Elbe shipping has been followed by an increase of the export. In the Ostrau territory there is such a strong demand that work is being carried on in shafts which for many years have been disused. The Northern Railway is reopening the Georg Colliery, where no work has been done for more than fifteen years. Gutmann Brothers and Archduke Albrecht, both proprietors of large coal works of that district, in a short time will open new shafts. Last year the animated export of Bohemian brown coals caused a shortness in the export of the Zwickau Works, Germany.

IRON.—No change of importance is to be noted as regards the situation of the iron market. There is a steady progress in activity, such as has not been observed for a long time. Prices in several branches tend to increase. Tinned plates have advanced 15fl. per ton. Large orders have been given this week: for instance, an order of the Northern Railway for the iron materials necessary for all the year; the Sud-Nord-Deutsche-Verbindungs Bahn (branch of the North-Western) ordered from a home manufactory ten goods locomotives, with tenders; and the city of Vienna gave an order for iron water mains amounting to 12,000fl.

ELECTRICAL ENGINEERING.—Ganz & Co., of Budapest, have resolved to erect, within their own waggon manufactory, a trial line of the Zipernowsky railway, and the work connected with it has already been begun. Although the demand for glow-lamps is very active, lamp makers are decreasing prices to meet the foreign competition. Last week the price was decreased from 1·85fl. to 1·35fl. Three years ago the price of a 16 c.p. glow-lamp was 3·50fl. The Vienna Agriculture Exhibition, 1890, will be lighted by electricity, and Siemens & Halske are to supply the installation. Besides the ordinary lighting by glow and arc lamps, the company will supply the electric light for the fairy fountains which are being brought from Paris.

EXHIBITIONS.—In September next an Exhibition will be held at Graz, the chief centre of the iron industry in Styria. The exhibits will be mostly the products of the district. The Emperor will be the patron.

BRUSSELS, 28TH JANUARY, 1890.

THE COAL MARKET.—The strikes have now come to an end, thanks to the masters having given way to the men, and work has been resumed at all the collieries. The market is therefore less strained, and business is settling down into its former briskness. During this time of discontent about 300,000 tons of foreign coal have been imported, and worse still, most of the large markets have contracted for the supply of German and English coal for three months longer. It is thus evident that both masters and men will have to pay dearly for their selfishness and folly. The feeling in the market at present is a little mixed, for there is no knowing what turn the prices may take, and until things have gained their legs again some amount of uncertainty will prevail.

THE IRON MARKET.—The iron trade is becoming more settled now in consequence of the termination of the coal strike. The current prices of iron would have been ruinous, and it was impossible to see how an advance could be obtained. It is, therefore, best that the industrial markets should be conducted with method and calmness. Pig iron is scarce, and firm in price. Work is plentiful in the rolling mills and in the workshops, although the prices continue high. Girders, joists, and plates are in the best position, and the tendency is in the most favourable direction. The prices of old iron show a great confidence in the future of the market. The producers have learnt something by the recent scarcity of fuel. For instance, they all confess that they have found the English coals superior to the native qualities.

GLASS WORKS.—During the past week the market has been without movement on account of the possibilities of the makers having to advance their rates. Now that the coal strike has been settled things will go on more in their normal condition. The absence of business from the United States is causing a good deal of surmising, but of course it is to be accounted for by the lower price of glassware at New York.

ELECTRIC LIGHTING IN BRUSSELS.—The disputes as to the granting of the concessions for the electric lighting of Brussels are still raging violently in the Municipal Council, and the two parties are arguing and exposing each other. M. van Rysselberghe explained his system publicly, and he seemed very confident that he could satisfy the council if they would only trust him. The discussion, however, has so far ended where it begun, and altogether electricity has lost some of its vogue.

DÜSSELDORF, 28TH JANUARY, 1890.

COAL.—The situation is again greatly strained, and the uncertainty of the future of the coal market weighs heavily upon trade. The colliery owners having refused to entertain the demand of the miners for a 50 per cent. advance in the rate of wages, the leaders are organising their forces for another struggle. The general opinion is that they will modify their claim to the extent of 25 per cent. and risk another conflict. As the Belgian markets are now practically closed to us for several months to come, the

Digitized by Google

prospect is disquieting. The estimated requirements of the Prussian State railways in the fiscal year of 1890-91 is, for coal and coke, 2,608,818 tons.

IRON.—It can hardly be said that the iron market has improved within the last week, though prices have in some directions advanced a little. The upward tendency which has again become distinctly marked is due, not to a prospect of brisker trade, but to fears of another interruption of the production excited by the threat of the colliers, in both the Westphalian and the Saarbrück districts, to bring all industry to a standstill by another general strike. Consumers, apprehensive of yet higher prices for iron, are seeking te place fresh orders for distant delivery, but sellers are reluctant to entangle themselves in fresh contracts. Hence, though the demand is stronger, business has shrunk rather than expanded. Some disappointment is felt over the railway estimates for the fiscal year 1890-91, which are less than they were expected to be. The requirements are 84,962 tons of rails, 27,838 tons of small iron, and 39,415 tons of metal sleepers, a total of 152,215 tons of iron and steel for the permanent way, the estimated value of which is 22,622,900 marks.

PETROLEUM TANK TRANSPORT.—The firm of J. W. Hannesen, of Ruhrort, importers of American petroleum, have just set in operation a tank transport system between Bremen and Ruhrort. The tank-waggons are of 10 tons (seventy barrels) capacity. The petroleum is run into them at Geestemünde, through pipes laid from the vessel, and discharged into casks at the railway station at Ruhrort, whence it is despatched to consumers in all parts of this division of the country.

LILLE, 28TH JANUARY, 1890.

TEXTILE MANUFACTURES.—The sluggish tendency of business in the market for linen goods appears to be passing away. This week much greater activity prevails, and the turnover will compare very favourably with that of last week. Within the last few days the agents of several important houses, both native and foreign, have arrived at Armentières, and buying has been brisk. As a consequence the tone of affairs has improved, and manufacturers have begun to regard the future hopefully. The latest reports of the woollen trade at Roubaix are also encouraging. The declared value of the linen and hempen fabrics exported in 1889 amounted to £375,920 against £331,680 in the previous year, while the imports increased from £209,920 in 1888 to £237,040. The declared value of the woollen fabrics exported amounted to £13,427,440 last year against £12,935,000 in 1888. In the same time the value of the foreign woollen goods imported declined from £2,607,040 to £2,543,440.

FLAX AND YARNS.—There is now an abundant supply of Walloon, Douai, and Bergues flax in the market, and the demand is active. Prices remain unchanged. Notwithstanding the higher prices of Russian goods, a somewhat increased volume of business has been transacted within the last day or two. The market is quiet for tows. Spinners are trying to obtain higher rates for yarns to compensate the increased cost of the raw material. So far the only result has been a restriction of business. This remark applies also to jute yarns. The influenza epidemic has reduced the production of yarns fully 20 per cent. in the last two weeks.

COLLIERY VALUES.—The state of the market for shares in colliery companies is a good indication not only of the condition of the coal mining industry but of trade generally. The following differences are therefore instructive. The values are in francs per share, and represent the market prices on January 1st and December 31st, 1889:—Aniche, 9,225, 12,040; Anzin, 2,725, 4,250; Bruey, 11,500, 12,100; Bully Grenay, 1,250, 1,750; Courrières, 28,500, 36,000; Douchy, 2,305, 4,500; Dourges, 5,795, 8,710; Lens, 20,355, 23,200; Liévin, 4,255, 8,000; Marles, 14,250, 19,100; Meurchin, 2,400, 3,600; Ostricourt, 215, 350; and Vicoigne-Nœux, 16,550, 20,000.

AMSTERDAM, 27TH JANUARY, 1890.

ACCIDENTS IN FACTORIES.—The King has manifested the greatest interest in the proposed Exhibition of appliances tending to minimise dangers to life and limbs of workmen in factories and workshops, and also in the projected association of factory owners with the same object, to both of which I referred in my last letter. His Majesty has consented to become the patron of this association. Meanwhile, the committee of the Exhibition, to be held in the grounds of the Amsterdam Crystal Palace, has issued a programme, from which it appears that the collection will have an international character, and will form the nucleus of a permanent museum of factory hygienics. An international congress on the same subject will meet in the period during which the Exhibition is held. The Exhibition will be opened on the 16th June, and probably close on the 31st August following. Exhibits have to be forwarded to the Secretary of the Executive Committee, Mr. Van Deinse, at the Amsterdam Crystal Palace, not later than the 26th May next. Space is not to be charged for, but all expenses have to be borne by the exhibitors, and the committee will endeavour to arrange for them special railway and steamboat rates. Medals and the usual other marks of distinction will be awarded by a jury. In connection with this interesting subject, it is to be noted that the Common Council of Amsterdam has passed the local Bill, enacting liability of contractors towards their workmen for all accidents while carrying out works for the town. Various speakers opposed the measure, arguing that the town could not look after the insurance of artisans generally, even those not in the employ of the town authorities, without also stipulating their hours of labour and their rate of wages. Others objected because the town itself does not insure any of its own employés against accidents or death, although a project, also providing for old age and invalidation through sickness, is in course of preparation. But the Bill was carried by a substantial majority.

POSTAL MATTERS.—The Government is preparing a Bill for the better regulation of the Dutch postal service. It is proposed to increase the rates for printed matter, which certainly appear low. A newspaper, for instance, and a visiting card, may be sent for half a cent. As five Dutch cents have the same value as an English penny, the above rate is less than half a farthing.

AGRICULTURE.—The Royal Commission of Inquiry into the economic condition of the agricultural classes in Holland has completed its protracted labours. The Commission will meet in May to consider and draw up its report.

A NEW TIN ISLAND IN EAST INDIA.—The latest reports from Singkep, an island belonging to the Lingga group on the east coast of Sumatra, state that the prospects of finding permanent tin deposits there, similar to those in Banca and Blitong, are highly favourable. The concession for working these mines is in the hands of a private company.

GRINNELL'S SPRINKLERS.—Some Dutch factories have adopted these sprinklers, and others will probably follow after the highly successful experiments that have taken place last week in Amsterdam, large fires being easily put out by them. It was stated by the representative of the patentee that at least 5,000 buildings are now protected by these sprinklers all over the world, although the system was only introduced in 1882, and that insurance companies readily grant a substantial reduction in their premiums where they find them installed.

COCOA IN SURINAM.—The cocoa factories of Holland will be able to produce the manufactured article very cheaply this year, the crop being reported enormous in Surinam.

THE DUTCH SOUTH AFRICAN RAILWAY.—Latest advices show that the works between the Portuguese frontier and Pretoria are now in full work upon the first section to Nelspruit. Many engineers are wanted, so many, in fact, that a sufficient number of Dutchmen cannot be procured, and the directors of the above-named company are consequently thinking of engaging a few foreign gentlemen.

SAVING OF LIFE AT SEA.—Some time ago a committee was appointed to inquire into the present state of the means of saving life at sea in Holland. It has just issued a most exhaustive and instructive report, from which we gather that the service, although entirely voluntary, is very effective. In the main, it is performed by three societies, and the committee does not propose to interfere with their useful work. It proposes that the Government shall not as yet undertake that work itself, but shall continue to pay the small annual subsidy of £240, which commenced in 1881, and shall also assist the societies in every way, by placing at their disposal the best rockets manufactured at the State factory in Delft, and combining the coastguard service with the lifeboat service of the societies. The committee expresses the desirability of making one national society for the saving of life at sea, combined with a fund for encouraging and rewarding the efforts of those who risk their lives in promoting the objects of the fund.

COPENHAGEN, 25TH JANUARY, 1890.

SWEDISH STEAMERS FOR THE ARGENTINE REPUBLIC.—Within the last week or two three Swedish steamers have left Gothenburg *en route* for Buenos Ayres. They are not new steamers but second-hand boats, which used to belong to the Göta Canal Company, and when they have reached their destination they will be used on the La Plata River. Both crews and captains are Swedish.

WOOD PULP IN SWEDEN.—Another wood pulp and paper manufactory is about to be erected in Sweden—viz., at Atrafors, Elfsborg. The concern is a limited company, with a capital of 500,000kr.

STONE INDUSTRY IN SWEDEN.—I have several times drawn attention to the increase in the Scandinavian stone industry. As an instance of this, I may mention that the export of hewn stone during last year from the Bohuslön district amounted to a value of 427,725kr.

RAILWAYS IN SWEDEN.—It appears to be the intention of the Swedish Government to push ahead with the Northern Main Railway Line (Norra Stambauen). This important railway will prove a great boon to a large portion of North Sweden, where means of communication are sadly needed. The last Swedish Parliament raised the vote for the year from 2,500,000kr. to 4,000,000kr., and in the present session endeavours will he made to obtain another handsome vote. A plan has been drawn up by a number of prominent railway officials.

SILVER IN NORWAY.—The Kongsberg Silver Works, which are the only ones of any importance in Norway, have not done particularly well last year. The production of fine silver was only about 5,800 kilog., and, in addition to the smaller output, prices ruled very low; the quotation has ranged between 110¼kr. and 116¾kr. per kilogram. The surplus for the last financial year of the Kongsberg Silver Works only amounted to about 170,000kr., whereas it has averaged about 450,000kr. annually for the three previous years. The present prospects are considered satisfactory. The Armen Mine, which yielded well all last year, continues to give plenty of good ore; the Kongen's Mine, which has now been worked to a depth of 620 metres, is also tolerably good in certain portions; and the third of the Kongsberg old principal mines, the "Gottes Hülfe in der Noth" Mine, has also yielded well, and continues to promise well. Several of the other less important mines have also been worked with more or less satisfactory results.

COPPER IN NORWAY.—The Röros Copper Works, which is the most important establishment of this kind in the country, has lately been considerably extended, and new machinery, &c., has been provided. Last year appears to have been satisfactory, all things considered, and there are very fair prospects of remunerative working for the future. This satisfactory result has only been achieved by adopting the most approved processes, whereby the cost of production has been reduced simultaneously with an increase in the output. Special railways have been built and everything has been done to facilitate the business. Along with the copper production goes a very important export of sulphur ore. There are a number of other copper works in Norway, none of which, however, can compare with Röros, neither as to size nor rational working. Should the price of copper, however, leave a reasonable margin, there are signs of an increase in the Norwegian copper industry, as a good deal of experimental working has taken place of late.

EXPORT FROM THE FÄRÖ ISLANDS.—During the year 1888 (statistics are somewhat behindhand in these parts) the exports from the Färö Islands comprised 30,310cwt. dried fish, 4,389cwt. salt fish, 1,615cwt. turbot, 1,105 barrels of train oil, 137cwt. glue, 1,000cwt. guano, 137cwt. feathers, 5,714 lamb skins, and about 30,000 woollen vests.

A PAPER HOUSE.—A portable house of paper has recently been constructed in Hamburg. The walls consist of double layers of paper, of which the interior one is impregnated against fire, and the exterior one against moisture. The paper is fixed in frames, which can easily be attached to each other. The house is intended to serve as a restaurant, and contains a dining room 90ft. long.

THE STATE RAILWAYS IN FINLAND.—These railways are doing remarkably well. The increase on last year's takings will, no doubt, be about 1,000,000 marks in excess of the previous year's, which were, again, 1,000,000 marks above those for 1887. The net profits had been estimated at 2,400,000 marks annually for the three yearly financial periods 1889 to 1891, but will, no doubt, reach 3,000,000 marks for last year.

TRAMWAYS IN DENMARK.—Few capitals have a better system of tramways than Copenhagen. The oldest of the various companies was an English one, which has now been doing very well for some 27 years; but the later ones are Danish concerns, although one of the newest has been built by an English contractor. The Nörrebro Tramway Company, Copenhagen, has just published its balance-sheet for its 22nd year, which is eminently satisfactory, showing a net profit of between 25 and 30 per cent. on the share capital.

MADRID, 27TH JANUARY, 1890.

DYNAMITE IN SPAIN.—Although there is a large dynamite works at Bilbao, there is a good opening for another such establishment in the centre of Spain to supply the markets of Linares, the coal basin of Belmez, and the large and increasing mining districts in the provinces of Ciudad Real and Estremadura. The greatest inconvenience and delay are experienced in getting regular supplies in consequence of the difficulties of carriage. The dynamite from Bilbao must either pass through two systems of railways, which are not on the best understanding with each other, or must go by sea to Seville, and thence a long distance overland. If making dynamite pays anywhere, it would do so in the centre of Spain. The Bilbao works are reported as having done a good business for many years.

IRON ORES.—The price of iron ores at Bilbao is still looking up, and the last reports are to the effect that sales have taken place at 9s. 3d. for good Rubios, but the worst part of it is that the demand is much above the means of supply. Some of the Mediterranean mines are now making sales at improving prices, but the means of shipping are very far from being equal to the requirements.

THE AURRERA FOUNDRY COMPANY.—This company has been lately organised with a capital of £60,000, and has the best chance of being a very well paying business. The capital was obtained with the greatest ease at Bilbao as soon as the business was offered.

CHEAP RAILWAY RATES.—A most remarkable contract for the carriage of coals is reported to have been made between the Northern Railway Company and the Marquis of Comillas, the owner of some important coal mines in Asturias. The distance to be run from Santullano, the principal Catalonia market, is about 1,200 kilometres, or, in round numbers, 750 miles. The carriage is to be made at the cheap rate of 0.32d. per mile. Other conditions are that the quantity is to be not less than 120,000 tons per annum, to be carried in complete trains, and to pay for that quantity as if it was carried even in case that for any reason it was not offered to the company for carrying. Anyhow, it is the lowest rate that has ever been made in any country in Europe. It is just to say as an explanation that the Marquis of Comillas and his group of financiers are very large shareholders in the Northern Railway Company.

THE WEBB AND THOMPSON STAFF APPARATUS.

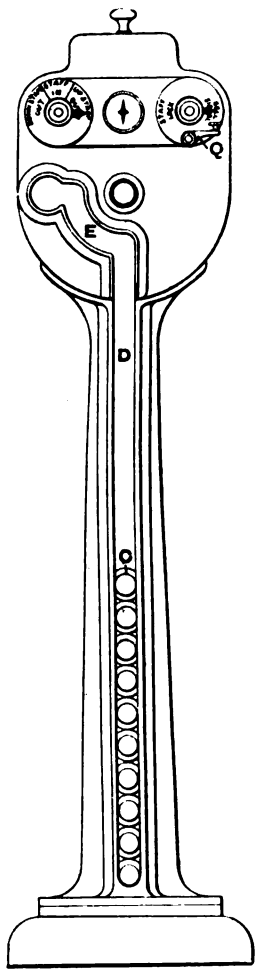

FIG. 1.

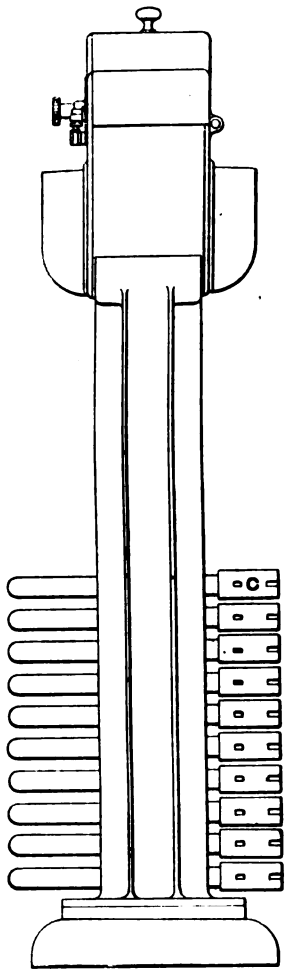

FIG. 2.

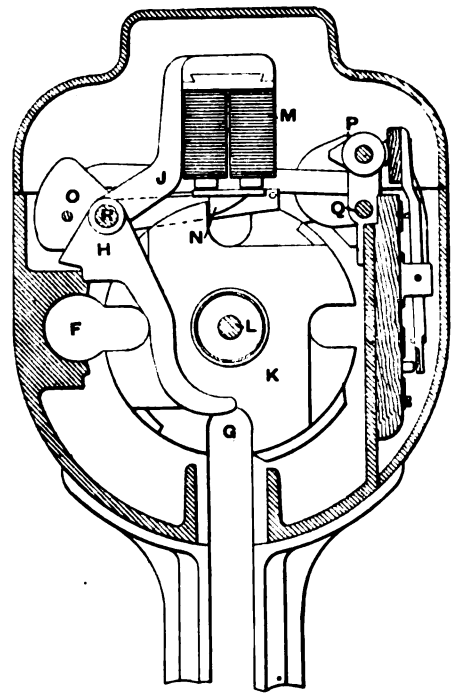

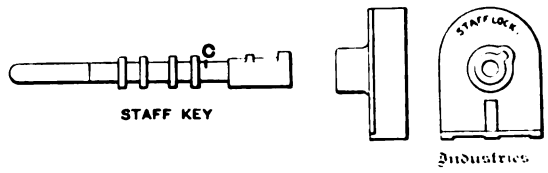

FIG. 3.

THE WEBB AND THOMPSON STAFF APPARATUS.

In view of the recent intimation by the Board of Trade of their intention to enforce their powers as to the completion of interlocking, &c., it will be interesting to railway managers to have a description of a new apparatus which has recently been perfected for the control of trains and the locking of siding points on single lines of railway. The "staff and ticket" system of working single lines is too well known, as also are the delays and inconveniences resulting from its use, to require any explanation; suffice it to say that, after an existence of over thirty years, it may be looked upon—certainly on busy sections of lines—as obsolete, and it has already in many cases given way to the well-known "tablet system." Further experience has resulted in the production of an apparatus similar in principle but much simplified and improved and possessing several special features. From our illustration it will be seen that ordinary train staffs are employed, the railway officers of the Board of Trade preferring the retention of the old-fasioned staff to any equivalent, and these staffs are each provided with a key by means of which sidings connecting with the main line can be securely locked.

It would take too much space, and demand too elaborate diagrams, to explain the action of the apparatus in all its minutiæ, but a general description may be of service. In the case of a single line between two points A and B, there can be no collision if there is one staff which has to be carried by any train passing between them. But if two trains want to go from A to B, and the first carries the staff to B, and leaves it there, the second train is delayed till another comes from B to A and brings the staff back. This apparatus supplies a number of staffs, but is so arranged that there can only be one staff out at a time. Figs. 1 and 2 show a pillar with 10 staffs. To remove a staff it is raised along the slot D, round the curved channel E to the enlargement, where it can be pulled out. In removing it it turns a set of discs, shown in Fig. 3, through a quarter of a circle; as it passes up the curved channel E it moves the notch G to the position opposite F. The discs are notched, as shown in Fig. 3. The discs are locked whenever a staff is removed. For instance, if all the staffs are in, and one is to be taken out, on raising it it is held by the discs which are mechanically and electrically locked. The rings C on the staffs release the mechanical catches, but an electrical catch, J, M, N, has to be released. This is done by a circuit through the other station, a single line wire being employed for both the apparatus and bells. In returning a staff the discs are rotated back a quarter turn. As each set of discs has four notches it can be in four positions. Calling the position of the bottom notches (1) when no staff is out, the notches on the right side (2), the top notches (3), and the notches on the left side (4). Now taking out a staff from A and putting it in at B, moves the A discs to (2) and moves the B discs to (4), another journey moves them back to (1) if from B to A, or to (3) if from A to B. Thus, whenever a staff is out, the two sets of discs are one at an odd number and the other at an even number, but when the staff is put back they are both at an odd or at an even number. The electrical catch can only be liberated when the sets of discs are both at odd or at even numbers, so that more than one staff at a time can never be out. Then again the apparatus is so arranged that a staff may be withdrawn for shunting purposes, which admits of shunting being performed on the single line with absolute safety and the cost of providing covering signals avoided, the staff being replaced when the work is complete. Combined with these special advantages the apparatus admits of a single line being utilised to its fullest capacity, as a staff is always at hand when wanted; and the traffic is not disarranged by specials or trains running out of course, as they can be passed forward without a moment's delay so soon as a preceding train has cleared the section, and as each train carries a staff, and each staff is provided with a key, all siding points can be secured at a trifling cost, and the cost of providing signals avoided; and finally the ordinary block instruments may be dispensed with, the apparatus itself being the most perfect block instrument known. In all apparatus of this kind it is most essential that the parts should be strong and simple in design, and capable of withstanding rough usage, and proof that this has been satisfactorily accomplished is found in the fact that a busy section of line has been worked for two years without any failure, and a set of apparatus put to work in the Paris Exhibition was removed at the close in perfect adjustment and order, although it was in constant use and received no attention. We may add that the apparatus is the joint patent of Mr. F. W. Webb, M.Inst.C.E., and Mr. A. M. Thompson, M.Inst.C.E. It has been approved by the Board of Trade, and has been adopted by the London and North-Western Railway Company.

THE STANLEY CYCLE SHOW.

The thirteenth annual exhibition of cycles and accessories, known as the Stanley Show, was opened at the Crystal Palace on the 24th inst., and closes on the 1st prox. The show was first held last year at the Crystal Palace, and was very successful, and this year the number of exhibitors has grown from 185 to 200. Two-thirds consist of the "safety," or geared-up bicycle type, and the remainder are tandems, bicycles and tricycles for two riders, twin bicycles, tricycles, and ordinary bicycles. The last-named type is coming back into partial favour again, as it is now made with a larger back wheel, and with the saddle placed farther back from the handles, thus giving greater security to the rider. Diamond-shaped frames and half-diamond frames appear to be coming into general favour. Attention is being given to the middle-aged rider by the introduction of a joint in the frame and springs to diminish vibration, and several makers exhibit specimens of this variety of machine.

Mr. J. Marston, of Wolverhampton and Holborn Viaduct, exhibits some neat safeties, in which the frames are made of double tubes ½in. diameter instead of the usual large size tube. With a 30in. front wheel and 28in. back wheel, both with ¾in. tyres, the weight is reduced to 36lb. for a full roadster, whilst a racer of the same pattern is 30lb. This maker shows the lightest machine we noticed, viz., a racer bicycle with 26in. equal wheels, the weight being only 15½lb. In some of the cycles shown by this maker the driving chain can be tightened by means of Marston's patent eccentric chain adjustment. This is accomplished by the bearing of the crank axle being carried in an eccentric which can be turned round as the chain stretches until the tightening length is equal to the throw of the eccentric.

One of the most striking objects in the Exhibition is a Hansom cab on five wheels, the front small wheel being a steerer and the four wheels behind the cab being driven by four riders. This machine is exhibited by the Coventry Machinist Company, and has been manufactured for the Sultan of Morocco. The interior of the cab is well upholstered, and it contains a sliding seat on which the Sultan can sit cross-legged. The machine can be steered from inside the cab or from the rear by the riders. The machine is highly finished, the bright parts being all nickelled, and is a good specimen of what can be done in the cycle trade.

A novelty is shown at the Pneumatic Tyre Company's stand. The usual solid rubber tyres are replaced by hollow rubber tyres 2in. in diameter. These are inflated by a special force pump, and it is claimed by the makers that they deaden vibration. The tyre is not of uniform thickness around its circumference, but is thicker on the wearing surface than elsewhere. A safety bicycle fitted with the special tyre is exhibited by this firm, and though it has been ridden for 1,000 miles the tyre appears to be none the worse for wear. Three or four other firms also exhibit this particular form of tyre.

Among the novelties is a "water cycle," shown at Stand 230. This boat is worked by two riders in the ordinary cyclist manner, who drive a crank shaft which is geared to the paddle shaft. The boat is balanced by a pair of small outrigger floats, one on each side, and they can be raised or lowered by a lever within reach of the drivers. The boat will carry four persons.

A counterpart to the water cycle is to be found in Rudge's "road sculler," fitted with hand-propelling gear and a sliding seat. This machine has been designed for the use of oarsmen. The machine exhibited by the Rudge Cycle Company, Limited, has 40in. side wheels and a 22in. front wheel. This firm has a good show, and in addition to ordinary machines they exhibit their "invalid" tricycle and their "parcel carrier." Their novelties for the season consist of a spring frame and a spring handle.

Mr. George Cousins, Birchington-on-Sea, Kent, exhibits a very light safety bicycle. The frame itself is its own spring, and it is formed of ½in. square steel. The back wheel is large and the front one small. The seat is placed back about 45 deg. from the driving axle, and, instead of the usual small saddle, the machine is fitted with a broad seat and a back rest. The weight of the machine is 48lb.

The Goulden Syndicate, Limited, Clapton, London, show a variety of their "Golden Era" cycles, including

Digitized by Google

a military safety, in which the rifle is simply laid in sockets and not fixed. The frames are rigid, but the vibration is taken up by a spiral spring insulator on the hind wheel.

Mr. John Pollitt, Lower Mosley Street, Manchester, shows several machines fitted with the "Collier" instantaneous change gear. This is a contrivance by which the cycle can be reduced in speed for hill climbing. It contains one pinion only, which drives the chain wheel at the lower speed, which reduces the speed of the machine one-fifth. At the higher speed the pinion remains in gear with the chain wheel but does not work, and the whole is revolved as an ordinary chain wheel. The speed can be changed from the handle bar by a spring catch and levers withdrawing a bolt, which locks the pinion and chain wheel together. The gear is covered by a dust cap in actual work, and can be fitted to any ordinary machine.

Notices of Meetings.

NEXT WEEK.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, February 3rd. Mr. A. H. Allen, "Metallic Compounds of the Phenols;" Mr. Watson Smith, "New Method of Hardening Steel for Projectiles;" Mr. Losawitch, "On Bromanil."

SOCIETY OF ENGINEERS.—Monday, February 3rd, 7.30 p.m. Presidential Address.

INSTITUTION OF CIVIL ENGINEERS.—Ordinary Meeting, Tuesday, February 4th, 8 p.m. Paper to be read with a view to discussion: "Bars at the Mouths of Tidal Estuaries," by W. H. Wheeler, M.Inst.C.E. Students' Meeting, Friday, February 7th, 7.30 p.m. Paper to be read: "Reclamation of Land on the River Tees," by Colin P. Fowler, Stud.Inst.C.E.

CHEMICAL SOCIETY.—Thursday, February 6th, 8 p.m. Papers to be read: "The Oxides of Nitrogen," by Prof. Ramsay, F.R.S.; "Studies on the Constitution of Tri-derivatives of Naphthalene," by Dr. Armstrong and W. P. Wynne; "On the Action of Chromium Oxychloride on Nitrobenzole," by G. G. Henderson, B.Sc., and J. Morrow Campbell, B.Sc.

PRICES CURRENT, 29TH JANUARY, 1890.

Quotations at per ton, unless otherwise specified.

METALS.

Spelter:	Ordinary	£25	2	6	to	£25	5	0
Copper:	British Cakes and Ingots	57	0	0	,,	58	0	0
,,	Chili Bars, G.O.B.'s	48	17	6	,,	49	0	0
,,	Other sorts, G.M.B.'s (equal to Chili Bars)	49	0	0	,,	.....		
,,	Manufactured (strong)	66	0	0	,,	.....		
Lead:	Common Pig	14	15	0	,,	15	5	0
,,	English Sheet	15	15	0	,,	16	5	0
Tin:	Straits	94	0	0	,,	94	2	6
,,	Australian	94	5	0	,,	94	7	6
,,	English Ingots	99	10	0	,,	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER is quiet, without any change in manufactured; ingots and raw copper are slightly lower, for the same reason as mentioned last week, viz., the high Bank rate. The fall in Scotch warrants seems to have affected metals generally, as they are all dull.

TIN: A fair business has been done in Straits, and a considerable quantity has been sold for February. English tin is, however, quiet.

LEAD is lower, and not much doing.

SPELTER keeps fairly steady, though price is about 2s. 6d. per ton lower than last week. There is a fair demand.

PIG IRON.

Messrs. Raby, Fell, & Co., Manchester, quote as follows:—

Middlesbro' Warrants, No. 3		55/6	Cash
Scotch Warrants, m/n		56/2	,,

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—We have to report rather less activity in the demand for general chemicals. Bleaching powder is quiet, but prices are steady, and makers are particularly strong in their ideas for forward business. Caustic soda remains firm, makers having plenty of orders on hand, but not much new business is being done. Soda ash still scarce. Soda crystals dearer. Sulphate of ammonia has fallen and is very depressed. Sal ammoniac has advanced £1 per ton. Benzoles have advanced about 6d. per gallon. Carbolic acids are unchanged. Makers of oxalic acid have had a push of orders, and are, consequently, expecting higher prices. Acetates of lime are quieter.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, Jan. 30.—*Iron.*—The market has been startled by the announcement that the forge masters of the Nord have advanced their rates for bars and joists to 164s. This makes a minimum of 176s. here necessary. There is but little business doing. It is otherwise, however, in the provinces. In the Haute-Marne wire manufacturers are overwhelmed with orders. In the Nord the market is animated, the demand for bars, joists, and plates, particularly the last, being exceptionally strong.

Metals.—The metal market generally is weak. Copper has lost a few points. Chili bars, £54; English best selected, £60. Tin has given way more seriously. Banca, £105; Straits, £100. Lead has followed in the same direction, the current quotations being £14 8s. Havre and £14 16s. Paris. Spelter remains unchanged, at £26 Silesian. The amount of business done in spelter is small.

BERLIN, Jan. 30.—*Bourse.*—The prospect of another general strike of colliers in Western Germany caused a panic in the market for colliery shares, which were offered for sale in overwhelming quantities. Prices fell heavily, and in sympathy all other industrial securities drooped, particularly the shares of iron and steel companies. The downward movement has, however, been checked, and to-day some recovery has taken place.

Metals.—The demand for metals on the part of consumers continues strong and steady. The tendency of the market for good copper is still in favour of sellers. Mansfeld refined, £61 10s. to £62 15s. Tin remains dull at last week's prices. The demand for lead is a little slacker. Clausthol refined, £16 to £16 5s. For spelter the market is active and firm. Regulus of antimony has again advanced: English, £82 to £82 10s.

BRESLAU, Jan. 30—*Coal.*—The colliery proprietors having for the most part spontaneously advanced the rate of wages, the miners are settling down contentedly to work. The market is, therefore, less excited, and prices are steady. The coke ovens are being pushed to their utmost capacity of production. As the whole of their possible output in 1890 is already sold, the market is not sensitive to passing influences.

Iron.—The activity of the iron market tends rather to increase than abate. The demand is particularly strong for plates. A brisk business is being done in steel goods. In consequence of heavy buying of wire and wire nails, the prices of these articles have been again advanced. The current price for bars is 220s. a ton. Foreign orders for founders and machine makers are coming to hand plentifully. The former have advanced their rates 7½ and 10 per cent.

Zinc.—The labour difficulties which arose last week having been removed, the zinc market is steady again. There is no change to report in its general features. Throughout the industry the greatest activity prevails. W. H. spelter has been sold at 502s. a ton, but there is now a backward tendency.

DÜSSELDORF, Jan. 30.—*Coal.*—The situation in Westphalia has improved a little, the miners having decided, in view of the elections about to take place, to put off their proposed general strike till March 1. Prices for coal at the pits are practically the same as they were a week ago; but the merchants, who control a large proportion of the output, are asking higher rates.

Iron.—Business continues very active in all branches of the iron and steel trades. Prices are still advancing, though the movement is now relatively slow. Quotations for pig have not materially changed within the last few days. Foundry pig is more sought after. The total make of pig in Germany in December amounted to 391,523 tons. Total for the year 1889. 4,387,504 tons. Rolled wire and wire nails are in better demand. Rivets for boilers, bridge work, and ship plates are quoted 290s.

BRUSSELS, Jan. 30.—*Bourse.*—The improved aspect of affairs in the coal mining industry is reflected in the business of the Bourse. The market for industrial securities is slowly recovering from the effects of the late scare. Colliery shares are not now pressed for sale, and shares in iron and steel companies, which had dropped several points, are rising again. Shares in the best glass concerns are hardly procurable at the latest published quotations.

CHARLEROI, Jan. 30.—*Iron.*—The iron market is gradually resuming its normal aspect. Confidence in the future has in no degree been weakened by recent events, though much trade has been lost. That the pig iron manufacturers have no misgiving concerning the maintenance of prices is significantly shown by the fact that they are contracting for a year's supply of coking coal at 18s. 5d. per ton, equivalent to 28s. for coke. Business is brisk in plates.

Glass.—The syndicate of glass makers having decided to advance their prices 10 per cent. for the Continental, and 15 per cent. for the English markets, the situation has become more clearly defined, a circumstance which the men are turning to account in the agitation they have set on foot for a rise of 30 per cent. in wages. Frequent meetings are being called to discuss with their leaders the plan of action proposed by the latter.

WE have received an interesting little book from Messrs. Galloways, Limited, Manchester, showing the constructive progress of a boiler at their works. The book is capitally illustrated, and the various processes are described very fully.

HOME INDUSTRIES.

LONDON 30th January, 1890.

The Money Market.—There has been rather a slackening in the tension which has existed in the money market for some weeks. Considerable purchases of gold by the Bank of England have contributed to this result, though in point of fact such purchases do not affect the banking department, but must be held by the issue department against the notes paid out for the gold. The inability of lenders to maintain the high rates ruling a fortnight ago for loans to the Stock Exchange, in connection with the settlement this week, has helped to depress rates in the money market generally. The decrease in Stock Exchange business, due to the money stringency, has been so great that comparatively little money was required to arrange the account. Hence the falling away in continuation rates. The stock markets have improved a little this week after the general fall in the preceding week. Consols have risen as money has cheapened, and most home railway stocks have become a little brisker on account of the same influence, though operating in quite a different way. Foreign securities have fairly maintained their prices: American, Canadian, and Mexican railways have been rather more in favour, but mining, nitrate, and miscellaneous shares show a declining tendency. The fall in nitrate stocks has been especially marked.

Companies.—The following companies have been registered since our last report:—The Barberton Gold Mining Company, Ld., with a capital of £150,000; Aaron's Reef, Ld., with a capital of £200,000, to acquire lands, mines, &c.; Kent Ice Consumers' Manufacturing Supply Company, Ld., with a capital of £5,000; Roberts, Mart, & Co, Ld., with a capital of £40,000, to carry on the business of paper merchants, &c.; The Compressed Air Carpet Cleaning Company, Leeds, Ld., with a capital of £10,000; Oastler, Palmer, & Co., Ld., with a capital of £80,000, to carry on the business of tanners, curriers, &c.; Holroyds, Ld., with a capital of £60,000, to carry on the business of cloth finishers; The Mills Cycle Company, Ld., with a capital of £10,000; Robinson & Price, Ld., with a capital of £10,000, to carry on the business of cycle manufacturers; E. Lloyd, Ld., with a capital of £250,000, to carry on the business of newspaper proprietors, &c.; The Adventurers of Mexico, Ld., with a capital of £50,000, to prospect and explore for minerals, &c.; The Bangor Marble and Limestone Quarries, Ld., with a capital of £15,000; A. Attwood & Co., Ld., with a capital of £50,000, to carry on the business of engineers and contractors; The Bradley Room and Power Company, Ld., with a capital of £20,000, to erect a power loom weaving shed; The Standard Portland Cement Company, Ld., with a capital of £100,000; North Shields and Tynemouth District Tramways, with a capital of £6,000; The Glendinning Syndicate, Ld., with a capital of £10,000, to acquire a certain antimony mine, &c.; West Indian New Gold Mining Corporation, Ld., with a capital of £120,000.

Exhibition of Meteorological Instruments.—The Council of the Royal Meteorological Society have arranged to hold, at 25, Great George Street, Westminster (by permission of the Council of the Institution of Civil Engineers), on March 18th to 21st next, an Exhibition of Instruments and Photographs illustrating the application of Photography to Meteorology.

Junior Engineering Society.—The fifth annual dinner of this flourishing society was held on Friday evening last at the Holborn Restaurant, when Professor John Perry, F.R.S., the President, occupied the chair. Among those present were Sir James Douglas, F.R.S., Professor W. C. Unwin, F.R.S., and Professor T. Hudson Beare. After the usual toasts, Professor Perry, on behalf of the society, presented Mr. W. T. Dunn, the energetic honorary secretary and treasurer, with an illuminated address and a purse of gold, in recognition of his services during the past five and a half years. Mr. Dunn, in acknowledging the presents, briefly referred to the history of the society, and amongst other interesting facts mentioned that the society had quite recently increased in membership upwards of 40 per cent.

The Civil and Mechanical Engineers' Society.—On the 22nd inst. an ordinary meeting of the Civil and Mechanical Engineers' Society, the President, Mr. Henry Adams, in the chair, was held at the Westminster Palace Hotel, when a paper, entitled "The Present Aspect of Electric Lighting in London," was read by Mr. E. C. de Segundo. The author went over the questions of dispute, and described in detail the various installations at present being laid down and in operation.

The Sanitary Institute.—The following weekly lectures, commencing February 18th, have been arranged by the Sanitary Institute for the special instruction of those desirous of obtaining knowledge of the duties of sanitary officers. These lectures are a continuation of the courses previously held by the Parkes Museum, and it is proposed to repeat the course twice each year, to suit the requirements of persons preparing for the examinations of the Institute:—(1) Introductory lecture. Practical Considerations for Sanitary Officers, by Mr. E. C. Robins; (2) Water Supply, Drinking Water, Pollution of Water, by Dr. Louis Parkes; (3) Drainage and Construction, by Prof. H. Robinson; (4) Ventilation, Measurement of Cubic Space, &c., by Sir Douglas Galton, K.C.B.; (5) Sanitary Appliances, by Prof. W. H. Corfield, M.A., M.D.; (6) Scavenging, Disposal of Refuse and Sewage, by Mr. Charles Jones; (7) Food (including milk), Sale of Food and Drugs Act, by Mr. Charles E. Cassal; (8) Infectious Diseases and Methods of Disinfection, by Mr. Shirley F. Murphy; (9) General Powers and Duties of Inspectors of Nuisances—Method of Inspection, by Mr. J. F. J. Sykes; (10) Nature of Nuisances, including Nuisances the Abatement of which is Difficult, by Mr. J. F. J. Sykes; (11) Diseases of Animals in Relation to Meat Supply, by Mr. A. Wynter Blyth; (12) Sanitary Law, General Enactments, Public Health Act, 1875, Model Bye-Laws, by Mr. A. Wynter Blyth; (13) Sanitary Laws and Regulations Governing the Metropolis, by Mr. A. Wynter Blyth. A fee of six shillings for the course will be charged to cover expenses, and students attending the course will be granted free admission to the Museum and Library during February and March.

Electric Light at the British Museum.—For some years the reading room at the British Museum has been lit with arc lights, and the success of the experiment has been so great that the trustees determined to light the whole of the building by electricity. On Tuesday night last the new installation was first tried publicly. There is hardly a place which we could mention where the use of electric lighting is more appropriate, for the building is gloomy at any time, the use of gas is detrimental to the preservation of the many valuable contents, and the hours of admission will become more available to the ordinary mortal. The dynamos, lamps, &c., have been supplied by Messrs. Siemens Bros., and the steam engines by Messrs. Marshall, of Gainsborough. Altogether the new installation is a great success.

MANCHESTER, 30th January, 1890.

The "Hercules" Street Cleaner.—A trial of the machine bearing this name was made in and about the yard belonging to the Manchester Corporation on the 24th inst. The machine consists of a water tank, mounted on a frame sustained by two wheels, supplying a stream of water to a perforated pipe. At the back of the machine is a revolving roller consisting of a number of india-rubber flaps or arms placed helically in the centre boss. The action is that a copious stream of water falls upon the *debris*, and the liquid slush thus formed is thrust at one side by the rotation of the india-rubber roller, by successive stages, until it is placed in the side gullies where the water can drain away and the solid matter collected. The trial was witnessed by a number of members of the Highways Committee of Manchester and of other Corporations. While the roadway was fairly well cleansed, it was not more effectively done than by the brush machine at present in use. The roadways in Manchester being all paved with granite sets do not lend themselves so readily to the action of the india-rubber flaps as do wooden or asphalted pavements, and a considerable drag was put upon the horses by the adhesion of the rubber. The general opinion expressed was that, while for smooth roadways the machine would be serviceable, it was not well adapted to the rough ways of Manchester. The quantity of water used was also a matter requiring consideration, and, as the machine at present in use does not require any water, it was considered to be more suitable for this district.

Automatic Gas Supply.—Messrs. Fletcher & Murphy, of Manchester, are constructing an automatic supply meter, which is receiving a trial in Liverpool. By the use of apparatus similar in character to other machines of this class, a penny dropped into the machine will supply a proportionate amount of gas, the amount depending of course on the cost per 1,000ft.

Boring Machine for Shaft Couplings.—Messrs. Hetherington & Co. have just constructed a handy little machine for boring out the bolt holes in propeller shaft couplings, which, as is well known, are taper. It consists of a light bridge-shaped frame carrying a hollow drill spindle, up the centre of which a bar is passed, in which a slot is formed. The inner end of the boring tool fits the slot, and by giving the latter any desired angle the tool can be pushed outward as the bar is advanced. As the internal bar is prevented from having a longitudinal motion, the movement of the boring spindle inwards causes the tool to project from it in the manner described. The spindle is externally screwed so that a wheel correspondingly threaded acts as a nut, and when revolved feeds the spindle forward. In order to prevent breakage, the feed apparatus is arranged to slip if too great a "bite" is given. The machine is very handy, and can be easily moved about as desired, being kept as light as possible. In the event of a breakdown it is likely to be useful, as, by means of two binding screws, it can be fixed to the coupling in any position.

The Manchester Ship Canal.—The Consultative Committee appointed in 1886 to advise on the probable future of the above work paid a visit to the works near the Manchester end on the 27th inst. The works are now practically complete in some parts so far as the cuttings are concerned, and in the Salford Docks some of the walls are completed. In the case of the Manchester Docks, the concrete walls were put in before the excavations began, and these are far advanced. One of the straight cuts, which was to be filled in a week or two, being nearly finished, has been flooded prematurely, and it is likely that the necessary operations to complete will be dealt with specially by dredging or otherwise. At Barton the Committee found the section completed, and at Irlam the locks are far advanced. Owing to the floods it was not possible to proceed beyond Warburton, but the large lock at Mode Wheel and the construction of the gates for it were both inspected. The Committee will complete their trip on the 6th prox. Mr. Marshall Stevens, the traffic organiser of the company, is arranging for the visits of a number of parties of traders and others, in order to demonstrate the advantages of the canal.

The Linen and Jute Trades.—There is an improvement in the tone of business here, but, owing to the absence of American buyers, few orders are being given on the spot for the United States. In regard to the home trade, the demand for such goods as are produced in Kirkcaldy, Sinclairtown, and other centres, for the manufacture of coarse fabrics, is limited, but greater activity is looked forward to about February, when the wholesale houses will in many cases complete stocks, which up to the present have not been kept up to the full quantity. Damasks, diapers, and napkins have been in slightly better request in the made-up form. The sale of diaper cloths in the piece grows less every year, and the trade, like that of Macclesfield cut-ups, is now transacted through three channels, represented respectively by the manufacturer, maker-up, and wholesale distributor. Including the retailer, there are four intermediaries through whose hands the goods pass before reaching the consumer. The designs in Dundee fancy jute fabrics have proved popular, and the demand promises to develop even more largely than hitherto. There is no new feature of importance in linen threads, which are unchanged in price, notwithstanding the increased cost of production.

GLASGOW, 30th January, 1890.

Iron and Steel.—A lull seems to have supervened in the iron market, and the steel makers, though still busy, have experienced during the last week a falling off in new orders. The withdrawals of pig iron from Connal's stores have been exceptionally heavy within the last few days. On Monday alone there was a decrease of 1,575 tons. There is little new to report in the position of the iron market. Disappointed holders lose heart as they see prices drooping almost daily. The only business doing in shipping brands is of a very retail character, and the question is whether buyers will have to pay the prices asked to meet their requirements or makers will have to come down in price to meet the buyers' views. Prices are irregular; makers profess to be well sold, but holders of second-hand parcels are willing to sell some brands much below. Although good influential buying came into the market a few days ago, in the neighbourhood of 60s, the price continued to fall, quantities of warrants, Scotch, Cleveland, and hematite, being pressed for sale. On Tuesday the market rallied slightly.

Railways.—Rumours are rife about the Caledonian Underground Edinburgh Railway scheme. These suggested the abandonment of the idea, and, though they have been categorically denied by the directors, they are still current. The proprietors of property on the north side of Prince's Street are in arms against the line, and have even raised a voluntary assessment to oppose the Bill in Parliament.

Glasgow Tramways.—At the annual meeting of the Glasgow Tramway Company, the Chairman, referring to the dispute between the Tramway Company and the Corporation as to the terms of the new lease, stated that, if the lease were not renewed, the Company would compete with the Corporation or with any company that might lease the tramways by running services of omnibuses all over the city.

Cassel Gold Extracting Company.—An extraordinary meeting of this company was held on Monday last for the purpose of securing the sanction of the shareholders to the proposal of the directors to increase the capital of the company by £30,000. The chairman intimated that the whole of the amount had been underwritten by the directors and their friends, but that the stock would be offered to existing shareholders at par.

The Clyde Tunnel.—The ground on the south side of the river for the shaft of the Clyde Tunnel has been purchased at the price of £3 per square yard. Operations will be at once commenced.

Minerals.—The Scottish Mineral Oil Association have advanced the price of paraffin scale by ½d. per lb.—The Lanarkshire coalmasters have rejected the demand of the men for an advance.

Pollock's Gold Extracting Company.—A Press inspection of the full-sized machinery took place yesterday, the 29th inst., and a public demonstration takes place to-day and to-morrow. Mr. H. A. Hedley is the manager of the company.

Overhead Electric Wires.—Major Cardew, on behalf of the Board of Trade, visited Glasgow on Thursday last, and inspected the overhead system of wires for the supply of electric light from the central station of Muir, Mavor, & Coulson, Limited. The inspection was made at the instance of the Corporation.

(From our own Correspondents.)

LIVERPOOL, 29th January, 1890.

The Strikes at the Docks.—Considerable inconvenience has been caused by the dock labourers refusing to unload several steamers arriving from Belfast and other ports, where a strike is now going on. Handbills have been posted in different parts of the docks calling upon the men not to unload any of the Irish steamers until the men there have received what they call their "just rights." A large number of the regular men are very indignant at the present dictation of the Union, but as the number of members is so

Digitized by Google

small there is very little fear of the present rising reaching a serious crisis; all the ships get eventually discharged, and the inconvenience is only temporary. The labourers in the Liverpool Grain Storage Company's warehouse at the North End, numbering over 100, came out on strike on Tuesday, on account of the manager refusing to grant an increase of wages.

THE TRAMWAY COMPANY AND ELECTRIC CARS.—At the meeting of the shareholders of the Liverpool Tram and Omnibus Company last Saturday, the chairman, Sir David Radcliffe, referred to the electric cars which were about to be tried in Liverpool, and said the delay in trial was on account of the steep gradients, which necessitated the designing of special cars and apparatus. A letter was read from Lord Bury explaining these points, and stating that the experience gained by his company on the North Metropolitan Tramway at Barking compelled them to design cars of greater power than they had at first anticipated; that the experimental car was nearly completed, and that all the difficulties, as far as they could see, had been overcome.

LEEDS, 29th JANUARY, 1890.

THE IRON AND STEEL TRADES.—Old contracts continue to keep the finished iron and steel trades brisk, though the market is somewhat quieter, the cause being the reaction northwards. There is a disinclination to transact forward business. At the same time the impression is strong that the check is only of a temporary character, and locally quotations have not materially changed. Evidence of the flourishing condition of the engineering trade may be seen on all sides. Some of the large shops are still running a deal of overtime. Messrs. Hudswell & Clarke are well supplied with orders, both on home and foreign account. One of the specialties of this firm is their patent wrought iron pulleys, for which there is always a big demand. Messrs. Kitson & Co., and other firms in Hunslet, have large orders in hand for locomotives, tank engines, &c. Stationary and portable engines for foreign customers, chiefly in Paris and Mexico, are being turned out as rapidly as possible by Messrs. J. M. McLaren, while Messrs. Tannett, Walker, & Co. are maintaining their reputation for hydraulic machinery, and are fully employed on contracts for all parts of the world. Several sets of ponderous hauling appliances are being made by the firm for docks and railway departments. At the present time the orders for traction engines are not very numerous. Colliery proprietors have of late been more ready to renew plant and machinery, owing probably to the circumstance that prices are more remunerative than a few months ago. One of the last branches to feel the effects of any revival is the tool department of the engineering trade, and therefore the activity now prevailing in the tool shops is somewhat significant. There is a less demand for agricultural machinery. In reference to the wages and hours in the Leeds engineering trade, the masters have met the men in a most conciliatory spirit, and matters have been settled without resort to any extreme measures on either side. The minimum rate of wages demanded by the executive of the Leeds Amalgamated Society of Engineers for fitters, turners, and millwrights has generally been conceded. The demand was that the minimum rate should be 28s. a week instead of 26s. Moulders and others are now agitating for an advance.

THE COAL TRADE.—For every class of coal worked in West Yorkshire the demand is such as to give full employment to the miners. In some collieries additional men could be engaged. Steam coal is not so plentiful as fuel for domestic purposes, and coke is still dear and comparatively scarce. With the exception of best household coal, the prices remain firm, and that firmness is likely to be maintained in the face of the demand of the colliers for another 10 per cent. A successful Yorkshire colliery is that worked by the Lofthouse Colliery Company, which on Saturday declared a dividend of 10 per cent., and an addition of £2,000 to the reserve fund, making it £10,000, and leaving a balance of £3,407.

SHEFFIELD, 29th JANUARY, 1890.

THE COAL TRADE.—The growing scarcity of coal and coke, and the consequent increase in value, is giving proprietors confidence to lay down extra plant and machinery. Several new pit shafts are being sunk in this district. A new company has been formed to work the Duke of Portland's top hard coal at Bolsover, entitled the Bolsover Colliery Company, Limited, with a capital of £150,000. The colliery deputies of South Yorks and Derbyshire are forming a union to protect their mutual interests. South Yorkshire surfacemen have demanded a reduction of working hours to 54 per week.

IRON AND STEEL.—The iron market is rather weaker than usual, but there is reason to believe that the depression is only temporary. Makers have large orders in hand. Local makers are working to their full capacity on the best brands, and there is little demand for inferior irons. Heavy sections of steel rails are quoted at £7 10s. per ton; boiler and ship plates, £8 to £9; angles, £7 15s. Shipments to the United States are rather quiet. Messrs. Charles Cammell & Co. are extending their Cyclops Works for the production of tyres, axles, and general steel forgings. The Hadfield Steel Foundry Company are also extending their works for the production of steel castings.

CARDIFF, JANUARY 29th, 1890.

COAL AND COKE.—The steam coal market is firmer, and considerable difficulty is experienced by buyers in getting the vessels they have chartered stemmed for loading. Prices for steam coal are steady at 15s. 6d. to 16s. first quality, 14s. 6d. to 15s. 3d. second quality, and from 13s. 6d. for inferior descriptions. Colliery owners complain that even with these high prices they are not doing so well as would be conjectured, on account of the restriction to the output caused by the men working short time. Coke continues in excellent demand at last week's figures.

IRON AND STEEL.—The general tone of the pig iron market is quiet; in fact, there is no business to be done. Makers are well sold forward, and, for what little they have to spare, are quite independent and firm in their quotations. In fact, owing to the advance in raw material and fuel the cost of production is further increased. On the other hand, buyers are shy, and prefer to wait for lower figures, so it will probably be a question of development of events as to the future of the market. Steel bars are in good demand. Rails are steady. Tinplates are dull, buyers being determined to "bear" the market.

IRON ORE.—Arrivals have been more numerous, and the immediate wants of ironmasters have been satisfied. Prices are high, and about 10,000 tons Rubio has been sold at 17s. c.i.f. Cardiff or Newport, second-class quality. Freights from the ore ports are firmer, Bilbao to Cardiff being 5s. 9d.

MIDDLESBROUGH, 29th JANUARY, 1890.

PIG IRON.—There was full market yesterday, but business was flat. Prices were depressed, and buyers were doubtful about taking even the low figures quoted. During the past few days No. 3 G.M.B. could be got from second hands at 57s. 6d., but it is questionable if that can be done now. For delivery next month 58s. and 58s. 6d. is offered and 59s. is quoted. Warrants are cheaper, rising and falling daily as speculators find themselves placed. The average is about 57s. 6d. Hematite iron also fluctuates in price. Makers hold for 80s., but warrants may be had from 72s. 6d. to 77s. mixed numbers. On Monday, January 27th, the stock in Connal's store amounted to 184,016 tons.

SHIPMENTS OF PIG IRON.—The shipments compare favourably with those of last month, but unfavourably with those of the similar month last year. The main falling off is in the shipments to Scotland, which this year, up to the 27th, amounted only to 8,485 tons, whereas last year, to a similar date, they amounted to 25,088 tons. The total shipments for the month up to the 27th inst. amounted to 37,856 tons, as against 59,654 tons to a similar date last January. The shipments abroad, however, are much about the same.

MANUFACTURED IRON AND STEEL.—These industries are easier, and prices are not so strong. Iron ship plates are at £7 15s., angles £7 10s., bars £7 15s.; steel ship plates £8 15s., angles £7 10s., rails £6 15s., per ton, all less 2½ per cent. discount on trucks at works. The report of the accountant to the Board of Arbitration and Conciliation certifies the average net selling price per ton of manufactured iron, for the two months ending December 31st, to have been £6 1s. 4d., as against £5 15s. 5d. for the previous two months. In accordance with the sliding scale arrangement there will be an advance in the men's wages of 3d. per ton on puddling, and 2½ per cent. on all other forge and mill wages, after the 25th of January. The average net selling prices per ton during the two months were £6 2s. 8d. for rails, £6 1s. 4d. for plates, £6 4s. 5d. for bars, and £5 14s. 1d. for angles, against £5 11s. 7d., £5 15s. 5d., £6, and £5 7s. respectively for the previous two months.

SUNDERLAND, 29th JANUARY, 1890.

SHIPBUILDING AND MARINE ENGINEERING.—The members of the Amalgamated Society of Engineers on the Tyne and Wear have decided to accept the offer of their employers of 1s. per week increase, provided negotiations are at once opened for the remaining shilling demanded and the reduction of the working time on Saturdays by an hour. The other day three of Mr. John Dickinson's workmen were fined £5 each, and costs, for intimidating a fellow workman. No settlement of the drillers' dispute at these works has yet been made. The increased cost of coals may be expected to stimulate the adoption by shipowners of the latest economical development of marine engineering, and at least three of the local engine builders are prepared to take orders for quadruple expansion engines, and in two instances, it is stated, the designs are of the four-crank type.

SHIPPING.—The outward freight market is more active, coal cargoes being more readily obtainable, but there is not much improvement on the rates paid, despite the enormous increased cost of bunker coals, which presses heavily on short voyage steamers. There is a lull in the Black Sea and Mediterranean homeward market, but in a month or so a great improvement may be anticipated. The immense amount of tonnage absorbed by the American market, and the future prospects from the United States and Canada are good, and leave relatively little tonnage available for the Black Sea. The local coal shipments continue to increase, and to approach the normal condition. 70,357 tons were shipped last week, an increase for the week of 3,306 tons, 46,235 tons going coastwise and 24,122 tons abroad Other shipments included 800 tons of patent fuel, 100 loads of teak, 16,000 dozen glass bottles. The imports, timber, pig iron, flour, &c., were below the average.

NEWCASTLE, 29th JANUARY, 1890.

SHIPBUILDING.—Since November inquiries for new steamers have been steadily falling off, until, at the present moment, they are almost as rare as in the days preceding the advent of the existing briskness. The lack of new orders has not, as yet, affected the state of work in the building establishments, and can scarcely do so for some months to come, as the orders in hand at the close of the year were very numerous; but as these get worked out slackness in the yards must, if the present dearth of new business continues, necessarily supervene, as shipbuilders are not likely to fill empty berths by speculative building on their own account. If the opinions of gentlemen who have been all their lives connected with shipping and shipbuilding, and who have the best sources of information at their command, may be trusted, the main cause of the falling off of inquiries and orders is the increased cost of tonnage brought about by the considerable advances of wages that have taken place, combined with the rise in the value of material. The present price of new tonnage, indeed, may be looked upon as prohibitory, and until a fall in the cost of labour or material, or both, enables shipbuilders to offer lower quotations, shipowners are not likely to go in for additions to their fleets beyond what, in certain cases, may be rendered necessary by special circumstances. If the workmen insist on any further advances—and the tendency seems unfortunately to be in that direction—they will only all the sooner bring about that condition of things which will deprive large numbers of employment, and thus precipitate a return to the reduced wages rates which prevailed a couple of years ago.

THE COAL TRADE.—The Northumberland miners have made a demand for a further advance of 20 per cent. on the wages rates, and negotiations are now in progress to arrange a meeting between the representatives of the coal owners and the miners' association to discuss the matter. With respect to this question, it is very generally felt that the miners, having already received, since the commencement of the improvement in trade, several substantial advances, are now trying to exact too much, and unless they very largely modify their demand the resort to a temporary laying in of the pits may be forced upon the coal owners. Such an occurrence would, of course, be disastrous to all concerned, and it is to be hoped that the miners' representatives, who are mostly credited with a fair share of common sense, will use their influence to prevent it. The demand for all descriptions of coal remains strong, and prices still show an upward tendency. The shipment of coal and coke from Tyne Dock for the week ending January 25th amounted to 102,345 tons, being a decrease of 13,309 tons as compared with the shipments for the corresponding week last year.

CHEMICALS.—The chemical manufacturers on the river have not been, since the year began, by any means forcing their productions. The month of January, when compared with former years, will show that there has been a great falling off in extent of alkali, caustic soda, and crystal soda made. The work of demolition at the Tyne Dock works of the Jarrow Chemical Company has already begun, and the whole of the acid and caustic soda plant and machinery is being gradually removed. The stocks of crystal soda held on the Tyne amount to about 2,800 tons, showing, when compared with the same period last year, a decline of 800 tons.

DUNDEE, 29th JANUARY, 1890.

JUTE AND FLAX TRADES.—There has been little change in the condition of the staple industries of this district during the past fortnight. Advices from Calcutta state that the market for baled and loose jute is easier. There has been a considerable business done here on continental account. In yarns there is not much doing, but spinners are not willing to grant concessions, and quotations show little or no change. Only a moderate business is passing in jute goods, and the production tends to outstrip the demand It is reported from New York that prices are rather easier there this week, the price of 40 in 10¼oz. being about ⅛c. less per yard. Transactions in flax, both on the spot and on contract, have been of limited extent, and prices are rather easier notwithstanding an advance on the Exchange. Stocks of yarns are pretty large, and the sale is rather dull. Quotations, however, are unchanged. There has been a better demand for linens, both on home and foreign account, and the outlook is, on the whole, hopeful. The Admiralty contracts placed in this district are of smaller extent than usual. Messrs. Baxter Bros. & Co. have secured the largest share of the canvas and hammocking. The Boase Spinning Company, which carries on business in Fifeshire, has received a share of both also. Messrs. Richards & Co., Aberdeen, and Messrs. Hayward & Sons, Bridport, have got shares of the canvas. Messrs. Jameson & Co., Hull, have received the coal sacking contract. It is not yet known how the contracts for tent, duck, and linen sheetings have been allocated. The quantities of goods contracted for are as follows:—Sailcloth, 700,000 yards, against 825,000 yards last year; hammocking, 160,000 yards, against 150,000 yards last year; and coal sacking, 105,000 yards, against 60,000 yards last year.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, Bedford Street, Strand, London, W.C.*

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," at our London Offices, 358, Strand, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

BOUND VOLUMES OF Industries,

In half calf, gilt lettered, may be obtained at our London, Manchester, and Glasgow Offices, Price 20s. each.

FRIDAY, 31ST JANUARY, 1890.

CHINESE RAILWAYS.

IN our issue of the 18th October last we gave a sketch of proposals for the construction of a trunk railway in China, 700 miles length, intended to be the beginning of a network of railways which had been sanctioned by the Chinese Government. These proposals raised quite a flutter of expectation among financiers, engineers, and manufacturers, as they seemed to open up large expectations, not only of immediate profit, but also of immense future developments. At the time, and also on previous occasions, we tried to moderate these expectations, not only because we knew something of the cautious nature of the Chinese, but also of the involved diplomacy and varied motives which influence the action of Chinese statesmen. Our warnings proved to be justified, for not long after we were informed that the railway scheme, at least in its main features, had been postponed, and in a note in our issue of the 13th December we gave the reasons which seemed to have influenced those who were responsible for the change of policy. We further pointed out that the facts which we gave showed the extreme uncertainty of a continued rate of progress in China for some years to come, and we expressed the opinion that, while there would be a general tendency towards development, it would be slow, shifty, and uncertain, until the mass of the Chinese people are more thoroughly awakened, and we warned those of our readers who are interested in China not to be oversanguine in their calculations. Since the last-mentioned date we have given other instances of the changing policy of the Chinese, and notably in the case of Mr. Little in his endeavour to improve the navigation of the Upper Yangtse. Our opinions have been strongly confirmed by a well-informed correspondent of the *Times*, writing from Pekin, who, like all who have resided in an Eastern country, seems to have been very much amused at the brilliant flashes of utter nonsense which are emitted from time to time by the London daily papers when they write on Chinese matters, as it is generally observed that they allow their imaginations to run off with them, and found calculations based on suppositions which are altogether unwarranted. On the other hand, while this is true, we very often find that correspondents residing in foreign countries are one-sided. Sometimes they are too sympathetic with the native Government, and too much in love with the people, to allow them fairly to see all the difficulties in the way of any industrial or other enterprise. Oftener, however, they have been soured by disappointment, or disgusted with official routine and what to them seemed senseless inertia, and their prognostications are usually unnecessarily gloomy. The fact of the matter is few foreigners are able to judge fairly of Chinese official action. We admit that some of it may seem to be, or may be, due to craft or duplicity but, on the other hand, a considerable experience with Chinese officials of the higher class has shown us that they have thought deeply on the problems connected with Western civilisation. They clearly recognise the advantages of it, but at the same time they are not blind to the disadvantages, and they hesitate before they commit their country to the problems with which we are now confronted. This we believe to be the real reason at the bottom of the inertia which irritates foreigners, whatever the apparent reason may seem. In a recent article in the *Nouvelle Revue* the eminent economist, M. Leroy-Beaulieu, has a most interesting article on the Paris Exhibition, in which he gives the opinions of imaginary people of different nationalities on the lessons to be learned from the Exhibition. Although M. Leroy-Beaulieu wrote the supposed journals or letters himself, they are no doubt founded on a careful study of the opinions of people of the different nationalities. The Chinese Commissioner is supposed to tell his master that the Westerns are far behind the Chinese in all the useful arts, especially in the arts of government, but in machines the Westerns excel, and he says that what the Chinese must do is to adopt the machines, but to take very good care to prevent the importation of the Spirit of the West, for he thinks that steam and electricity have a habit of getting into the heads of men who use them; and hence the mania for movement and for agitation which has destroyed the stability of the French State.

It is well known, and it has been mentioned by the *Times* correspondent, that for some years past there have been in China crowds of people, of all nations and classes, who have been presenting schemes for railway projects with one hand, and offering unlimited cash on the most alluring terms with the other. Indeed, he remarks, the way great capitalists, through more or less authorised agents, have been forcing money on the Chinese without success has afforded proof of a degree of public virtue in China which would hardly have been credited by those who knew the corruptness of the individuals who compose the Government, and that these contractors, promoters, and financial adventurers have little realised the actual state of affairs; that the railway question has been merely used as a football between various competitors for power and wealth, and has not yet been once seriously taken on its merits. We would not care to hold up the Chinese officials as examples of purity and incorruptibility, but we are strongly of opinion that those who speak most on such matters have little occasion to be accusers, and we have no hesitation in stating that the foreign financial adventurers should not make accusations, as in many cases they have done their best to bribe officials to come to their terms. We are glad to say that in our opinion British merchants have seldom condescended to such ways of doing business, and in this we agree with the *Times* correspondent, who states that so far the Chinese oyster has proved a disappointment to the adventurers. Germans, French, Americans have made strenuous but vain efforts to open it. The English have held aloof, either from apathy or latent wisdom, and in the end they will perhaps be as near the goal as their competitors.

As to the rivalry for power between Chinese statesmen, we are not sure that it is any greater or any worse than with the average statesman in any country. Naturally, a policy of railway extension, which would alter the whole social, industrial, and economic conditions of the country, is likely to be made the plea for discussions and opinions on all sorts of subjects. The *Times* correspondent admits that the Imperial family, Li Hung Chang, with the Governor of Formosa, and possibly one or two other officials throughout the Empire, are thoroughly imbued with the railway spirit, and do all they can to give practical effect to it, but he thinks that the mass of the officials are indifferent on the subject. On the other hand, he says, there is an active remnant of influential men who have no creed, no principles, and no policy, except greed of money for themselves and bitter envy of all

Digitized by Google

possible rivals, and that this huge faction, actuated by purely personal motives of the most sordid kind, constitutes a real barrier to any sort of progress in the country. We think he has greatly exaggerated the two latter classes. The great mass of the officials may be indifferent on the subject, but not more so than in any other country, and they only require a start and direction to convert them into willing workers. The opponents of the railway schemes are likely to include many men who have thought over the matter very carefully, and are neither sordid, corrupt, nor envious, and would be quite willing to agree to Western methods if they could prevent the importation of the Spirit of the West, and keep steam, electricity, and money from getting into the hands of men who might misuse them. We believe that the crowds of adventurers who have found their way to China have done more to stop real progress than the Chinese obstructionists, as their methods and manners have disgusted all thinking Chinese. The *Times* correspondent states that the scheme to which we alluded in the articles we have named has been stopped in the meantime by two causes—jealousy of Li Hung Chang, and opposition on the part of the common people. No doubt there is a certain amount of jealousy, but it will gradually be overcome, and the scheme will be carried out as the opposition melts away. The superstitious reverence which the common people have for the graves of their ancestors, or "Fung Shin," as it is called, is no doubt a very powerful obstructive, and has a firm hold on the people in all places and of all classes, as they imagine that cuttings in hills and through graveyards would awaken the whole invisible fraternity and produce the most disastrous consequences. This feeling is, however, gradually disappearing, and they are beginning to see that railways are no worse, from this point of view, than roads and canals, with which the country abounds in all parts. Of course in China we find the same objections from the carters and the boatmen, and others engaged in the carrying trade, as we had in this country when railways were first proposed. But these will also soon disappear. The real cause of the stoppage in the meantime of the great railway scheme is, in our opinion, the financial one. The Chinese people have not sufficient confidence in the Government to supply the money, and the Government, on the other hand, wishes as far as possible to avoid foreign loans. If money had not been pressed on them to the extent that it has been, they would have had more faith in the good intentions of the lenders, and no doubt would have availed themselves to a considerable extent of foreign capital. In the meantime, the seventy-mile line between Tientsin and Tungchow is being proceeded with, and this will afford a most useful object lesson, and will do more to overcome opposition than any other arguments which could be used. We have a great respect for the intellectual powers of the Chinese, and we feel convinced that if they could get over the preliminary stage, they would enter on a steady, although slow, progress, which would make their country one of the great nations of the world, its immense resources and population giving it great possibilities for the future.

THE SCIENTIFIC WORK OF JOULE.

The first of the weekly evening meetings for the present year of the members of the Royal Institution took place on the 24th inst., when Professor Dewar, F.R.S., delivered an address on "The Scientific Work of Joule." Professor Dewar began his address by stating that, as the Royal Institution had always been associated with the great workers of physical science, it was thought that the death of Joule should not be allowed to pass without its recognition. The period between 1838 and 1843 was that within which Joule educated himself in experimental methods, and at this time he was principally engaged in the study of electricity and electromagnetic engines. His researches led, in 1840, to the discovery of the true law representing the relation between electric energy and thermal evolution. His great success was achieved by an elaborate examination into the relations of supply of electricity and its distribution, not only in the conductors exterior to it, but also in the battery cell itself. This law, which seemed so simple, was of the greatest importance. It was that the amount of heat produced by a given amount of electric current varied as the square of the intensity of the current, and directly as the resistance, always provided that a given unit of time were used. Joule saw that this was easily proved in a relative degree, but to account for the whole of the distribution of the current was more difficult. This led him to the study of electrolysis; and it was marvellous that, with the great difficulties which the method presented, he was able to discover all the impediments to an electric current, and to prove conclusively that the whole distribution of energy could be accounted for. In 1841 he had practically completely analysed the distribution of energy in the electric circuit; and he had discovered the law regulating the distribution of heat in all parts of it. In 1842 he had really his great discovery in hand, as was shown by a foot-note to a paper written on the 25th of January, 1842. It seemed extraordinary that always the most difficult and complex methods of dealing with a subject were at first taken; and to any one who read Joule's paper on the determination of the mechanical value of heat by means of an electric current it seemed astounding that he should ever have overcome his difficulties. To produce a thermal effect was easy enough; but the difficulty was to prove the permanent and persistent relation between the energy expended and the heat produced through the electric current. There were the fluctuations of the current, the effects of radiation, the movements of the air, and other circumstances to be allowed for; and Joule had to depend on very small variations of temperature, using, therefore, very delicate thermometers. By the end of July, 1843, Joule was able to state the quantity of heat capable of increasing the temperature of a pound of water by 1° Fahrenheit, and that was equal to, and might be converted into, a mechanical force, capable of raising 770lb. through a vertical height of one foot. After his first determination of the mechanical equivalent of heat, he stated that he had arrived at a nearly similar determination by a more direct method—namely, by the friction of water passing through small tubes. In all great scientific discoveries it was difficult to distribute merit exactly. There were those who, while admiring the broad and rapid generaliser, could not understand the patient and plodding experimentalist. Joule never pretended to be anything else but an experimentalist. He would go step by step through intricate masses of work and research and never generalise until he was perfectly sure. It was difficult to know how it was that Joule's great discovery had not been anticipated. Rumford, who first clearly defined the relation between the constant production of heat and the loss of motion from friction, went near to doing so. Sir Humphrey Davy continued Rumford's experiments in a different manner, and entirely dissipated the idea of the separate existence of caloric; and Young did much in analysing the position. After 1843 Joule several times, up to a late date, made fresh determinations of the mechanical value of heat, on each occasion varying his methods and ever reaching nearer to exactness. Thus in 1878 he stated that he found that 1lb. of water would be raised in temperature 1° Fahr. by 772·55 foot pounds of work. Besides the work on his mechanical equivalent, Joule was conducting in the forties elaborate investigations on the maximum density of water, specific gravity, and atomic volume. Joule's last research was long and laborious, extending over a period of nearly ten years, and was conducted with Sir William Thomson. The one subject of their research was the study of gases passing through narrow apertures, and the other the study of the velocity of bodies through air, and the temperature the bodies would ultimately attain by moving through air.

THE FORTH BRIDGE.

On Friday last, the 24th inst., the first passenger train passed over the Forth Bridge. The train left Edinburgh shortly before ten o'clock in the forenoon, and proceeded by the New Corstorphine and Dalmeny line to the Forth Bridge Station at South Queensferry. The following travelled by the train: Lord Colville of Culross, Chairman of the Great Northern Railway Company; the Marquis of Tweeddale, Chairman of the North British Railway Company, and the Marchioness of Tweeddale; Mr. Matthew P. Thompson, Chairman of the Midland Railway Company and of the Forth Bridge Railway Company; Mr. Wieland, Secretary of the North British Railway Company; Mr. Holmes, Locomotive Superintendent, and Mr. William Arrol. On the arrival of the train at the Forth Bridge Station, it was joined by Sir John Fowler, Mr. B. Baker, Mr. F. E. Cooper, Mrs. Cooper, Miss Cargill, Mr. Joseph Phillips, &c. The train passed on to the south approach viaduct at 10.20, and at 10.25 reached the south end of the South Queensferry cantilever. At 10.29 the train passed on to the north approach viaduct, thus occupying four minutes in crossing the bridge proper. The engine used was a recently built one, and was driven by Mr. Robert Ramsay, of the Locomotive Department, Cowlairs. During the passage of the bridge the Marchioness of Tweeddale, Lord Colville, Mr. Thompson, Mr. Arrol, and Mr. Holmes were on the locomotive, the Marchioness moving the regulator lever to start the engine. The train afterwards returned to Edinburgh with the party. The details of the arrangements for the official opening of the bridge by the Prince of Wales on 4th March next are not yet definitely settled, but it is understood that they will be somewhat as follows:—The Prince of Wales, the Duke of Edinburgh, and Prince George of Wales will arrive at Waverley Station, Edinburgh, on Monday, the 3rd March. The royal party will stay at the New Club, and on the evening of the 3rd the directors of the Forth Bridge Railway Company and the engineers of the bridge will dine with the Princes at the Club. The royal train will leave Edinburgh in time to reach the bridge about eleven o'clock in the forenoon of the 4th. After the train has crossed the bridge it will go on over the new approach railway to Inverkeithing, from which it will return to the bridge. At the connecting girder on the north side, the ceremony of driving the last rivet of the bridge will be performed by the Prince of Wales. At Inch Garvie the party will alight, and, should the weather be favourable, embark on board a steamer for the purpose of viewing the bridge from the Firth. The party will again join the train at Inch Garvie, and on regaining the approach viaduct at South Queensferry the Prince will declare the bridge open. After the ceremonial a banquet will take place at the works.

THE LATE MR. JAMES STEWART.

The death of Mr. James Stewart, of the well-known firm of iron tube manufacturers, of Coatbridge and Glasgow, will be regretted by a wide circle of friends. He died on the 12th inst., at his residence in Glasgow, in the 51st year of his age. For some months previous the deceased gentleman had suffered from anæmia, and to this he succumbed whilst yet in the prime of life. The firm of Messrs. Andrew & James Stewart is one of the oldest and most important of the tube manufacturing firms in the kingdom. The business was started in a very humble manner in 1861 by Mr. Andrew Stewart, who opened a modest workshop in St. Enoch's Wynd, Glasgow, where he limited himself entirely to the manufacture of gas tubes. He soon found ample employment there for the workpeople with whom he started, and encouraged by this success naturally sought to develop his business by taking up another department. But his premises in St. Enoch's Wynd did not admit of any increase of the work carried on there; and the production of boiler tubes, to which he was now anxious to direct his attention, had to be provided for elsewhere. Before the decade of 1861–71 was half run Mr. Stewart, having in the meantime taken in as partner his brother James (whose death we now record), looked about for a suitable site on which to make a fresh departure, and found it at Coatbridge. On the ground selected a workshop was erected which was the nucleus of the present extensive premises of the firm. The four acres which were then secured have since expanded into three times that extent, and the little workshop into a vast pile of buildings fitted with the most perfect appliances for carrying on the manufactures for which the firm is now well known. In close proximity to the works model dwellings for the workmen have been erected by the firm, and every acre of available ground around the original buildings has been acquired in order to meet the increasing demand for room which the expansion of the firm's operations has created.

Until 1882 the firm continued its business under the old designation, but in that year the concern was converted into a limited liability company, with a very extensive capital, held exclusively by the two gentlemen already named, and by seven of their managers and principal employés, who had been associated with the firm for many years past. The company thus remained practically a private one, and, apart from the loss occasioned by the death of Mr. James Stewart, remains to-day the same as when formed.

Mr. Stewart, who was the first Dean of Guild of the burgh of Coatbridge, and who at the time of his death was a Justice of the Peace for the county of Lanarkshire, a member of the School Board, and also held other public offices, was a man whose untiring zeal and industry made him superior to all ordinary obstacles.

THE LATE HORATIO ALLEN.

On New Year's Day the death took place of the oldest of American engineers, Mr. Horatio Allen, the most noteworthy feature of whose life was his participation in the introduction of the locomotive into America. He was born in 1802, and, after receiving a college education, he took up the study of civil engineering, and entered the service of the Delaware and Hudson Canal Company. During his connection with this firm both he and the chief engineer, Mr. John B. Jervis, were attracted by Stephenson's experiments, which were then taking place in England, and they recognised the fact that the locomotive steam engine had a great future before it. Therefore, in the year 1828, Mr. Allen sailed to the Old World, and purchased two engines, and on their arrival at Honesdale, Pennsylvania, in the following year, Mr. Allen conducted a trial himself. It was, however, found that the roads were not heavy and strong enough, and the efforts of Mr. Allen were turned to reducing the load per wheel, and he invented a type which has since been modified into the "Fairlie" engine. In conjunction with Mr. Jervis and Mr. Winans he introduced many improvements, and the three of them together were the promoters of most of the early American lines. In later years Mr. Allen devoted much of his time to hydraulic engineering, and he was also the leading member of the well-known firm of Stillman, Allen, & Co., of the Novelty Ironworks, New York, who supplied the heavy engines to the American steamers before the time of Cunard. For the portrait which we give above we are indebted to the *Engineering News* of New York.

THE INSTITUTION OF MECHANICAL ENGINEERS.

The forty-third annual meeting was commenced on Wednesday, Mr. William Anderson in the chair, when the report of the Council was read. The number of members gave a total of 1,856, being 50 in excess of last year. The reports of the Research Committee dealt with the subjects of a standard system of marine engine trials, the value of the steam jacket, the friction of pivot bearings, and the application of the periodic law to the mechanical properties of materials. The Council have had under their attention the question of the taxation of machinery, which of late has acquired very great importance through the efforts of professional valuers to increase the rateable value of factory property by including the machinery. The voting for the election of officers was then taken, and Mr. Joseph Tomlinson was announced as President. The summer meeting of the Institution will be held in Sheffield. The first paper read at this meeting was by Mr. Thomas Urquhart, superintendent of the Grazi and Tsaritsin Railway, South East Russia, on

The Compounding of Locomotives Burning Petroleum Refuse in Russia.

The author of this paper, with a view to satisfy himself on the question of the utility of compounding in locomotives, obtained the sanction of the Russian Government to alter one of the petroleum-burning locomotives running on the Grazi and Tsaritsin Railway in South East Russia according to his own plans. This altered goods engine was put to work on the 1st September, 1887, and subsequently tested, under similar conditions, against a non-compound of the same type, with the result that the compounded engine burned 22 per cent. less fuel than the other. On this practical basis the compounding of other locomotives was at once proceeded with. At the end of 1889 there were in daily use in the regular train service of this line twelve compound goods engines with six wheels coupled, and three compound passenger engines with four wheels coupled, while four other goods engines and two passenger engines were in the shops undergoing reconstruction.

The saving of fuel effected by the compounding was found to be, for the twelve goods engines, 18½ per cent. as a mean. This question has not yet been determined for the three passenger engines, but the author believes it cannot be less than 20 per cent. in the second or third notch of the reversing lever.

In the drawings of one of these compounded 36-ton goods engines illustrating the paper, the diameter of the high-pressure cylinder is 18½in., and that of the low-pressure 25⅝in., the piston areas being thus about 1 to 2. The original stroke of 24in. has been retained, and the boiler pressure kept at 135lb. to the square inch above the atmosphere. With the original eccentrics giving the valves a maximum travel of 4½in., and having an angle of advance of 30°, the indicator diagrams showed excessive compression in the high-pressure cylinder and too early a cut-off in both. These defects were remedied by extending the travel to 4¾in., and making the angle 20°. Indicator diagrams were given to show the useful effect of the changes made. In all these diagrams the author has added 10 per cent. to the mean pressure in each cylinder to allow for the effect of the pipe connection from the cylinder to the indicator.

To ascertain the correctness of the common opinion that the compounding of existing locomotives, while retaining the original boiler pressure, and also retaining one of the original cylinders to serve as the high-pressure cylinder in the compound, necessarily results in a considerable loss of tractive power, and at the same time to determine what are the relative tractive powers of compound and non-compound locomotives, a series of comparative trials were made by the author in the summer of 1889 with both passenger and goods engines. The results were shown in tabulated form, from which it appears that in the compound passenger engine the tractive power undergoes the following diminution relatively to the non-compound in the five successive notches of the reversing lever:—Loss in the first notch, 42 per cent.; in the second, 28 per cent.; in the third, 17 per cent.; in the fourth, 7 per cent.; and in the fifth (full gear), 5 per cent. For the compound goods engine the losses were 27, 17, 10, and 5 per cent. in the first, second, third, and fourth (full gear) notches respectively.

Besides the economy of fuel, the author believes that the compounding of the locomotives will result in a saving of not less than 25 per cent. in the cost of repairs, because the initial stresses are not so great on the bearings and other mechanism in the compounds, and because the force exerted by the pistons is continued upon the crank pins for a greater distance during each stroke. Moreover, the friction of the slide valves is much less in the compounds, the back pressure of about 60lb. per square inch under the high-pressure slide valve tending to ease it off the face, while the low-pressure slide valve is loaded to less than half the boiler pressure.

The author observed that a very small difference in lap of a slide-valve, outside or inside, has a great effect on the fuel consumption. In the drawings a longitudinal section is given of the two valves in that one of the twelve goods engines which showed the best results. In this case we have: High-pressure valve, outside lap 0·79in., inside clearance 0·06in.; low-pressure valve, outside lap 0·61in., inside lap 0·08in. The drawings show two different devices for relieving the pressure of the slide-valves on their faces.

The first four engines compounded had their high-pressure crank leading and the low-pressure following in forward running. But it having been observed that one of these seemed to work better and to develop greater tractive force when running backward, the order was reversed in those subsequently altered, with very satisfactory results. The author believes that the sequence of cranks has never before been taken into consideration. The only objection he sees to the low-pressure crank leading is that it gives too much power to the large cylinder and too little to the small, thus putting the engine out of equilibrium. This defect may, however, be in large measure remedied by increasing the capacity of the receiver.

To prevent a vacuum in the receiver being formed by the low-pressure piston when running down hill with the regulator closed, an air inlet-valve was placed in the receiver, and arrangements were made to mix with the cold air entering through this valve some of the hot gases from the smoke-box to avoid the cooling effect which would result from the admission of cold air. There is a starting valve of very simple construction on the receiver, worked by hand, for admitting boiler-steam direct to the low-pressure cylinder.

The first passenger engine compounded had a receiver capacity equal to the volume of one stroke made by the high-pressure piston; but in those subsequently altered the capacity was increased to 1·3 of that volume with good results, the indicator diagrams for the low-pressure cylinder coming out fuller. More recently, in the case of one of the goods engines compounded, the receiver capacity was further increased with still better results.

The author's experience leaves no doubt in his mind that compound locomotives are the engines of the future in all countries.

At the invitation of the President, a discussion on this paper was commenced, but the evening being far advanced it was, after a few remarks, adjourned till the following day.

Mr. Schönheyder doubted the accuracy of the results in so far as the 10 per cent. addition to the pressures allowed for the connecting pipes was concerned. He had known a loss of 30 per cent. in such cases. It would be desirable in future trials to eliminate that source of error. He was also of opinion that the slide-valve relief arrangements were not to be relied upon.

Mr. Beaumont said it was not clear how the 10 per cent. referred to was taken account of in the indicator diagrams. He would like to know why the author of the paper had increased the receiver capacity, for he, the speaker, failed to follow his argument in that particular. It would appear from what had been said that a progressive increase of the receiver capacity was accompanied by a corresponding increase in the power of the locomotive, a result which, to him, was not easily to be accounted for.

Mr. Tomkins thought that the saving in fuel seemed to be compensated by the loss in tractive power due to compounding. As for the economy in the matter of repairs, that was a question to be decided by experience. The author of the paper had adduced no practical results to support his opinion that there would be, as he states, a saving of fully 25 per cent.

Letters to the Editor.

WILLIAM MURDOCH.

To the Editor of "Industries."

Sir,—I thank you for your insertion of my letter of last week on "The Sun and Planet Motion of William Murdoch." To aid me in a sketch I am preparing of this distinguished man of science I shall be glad if you will kindly extend your courtesy still further by permitting me through your columns to ask your readers to favour me with any items of fact or anecdote bearing on his life and inventions. Besides being the inventor of the sun and planet motion, the D slide valve, which displaced the older cumbrous and complicated arrangement of levers and valves, and other equally radical and important improvements on the stationary engine, he was the first to discover and apply coal gas as an illuminant and as an economic substitute for oil and tallow.

Yours, &c.,
Alex. Murdoch.

2, Berlin Place, Pollokshields, Glasgow,
28th January, 1890.

STEAM BOILER LEGISLATION.

To the Editor of "Industries."

Sir,—Certain facts in connection with the "Halesowen" explosion have come to light, and from them I find I was in error in one of the statements contained in my letter of the 13th inst. The company who insured the boiler which exploded in the s.s. "Perseverance" is not defunct, as stated by me, but probably soon will be if there is a repetition of such disastrous events as have recently occurred. Trusting you may find room for this correction, so that the saddle may be placed on the right horse,

Yours, &c.,
Manchester, January 28th, 1890. S. Boswell.

COMMUNICATION BETWEEN ENGLAND AND FRANCE.

To the Editor of "Industries."

Sir,—I notice in your issue of the 10th inst. a letter signed "T. C.," in which the writer refers to a project for crossing the Channel, which, if I am not mistaken, tallies with a proposal made about sixteen years ago by my late brother, Mr. Theobald Obach, and his associate, Mr. B. Lebret, civil engineers, of Vienna. Since your correspondent, as he himself admits, writes solely from memory, it happens that his description is not quite accurate, and he makes the proposal appear more venturesome than it really is. The idea was to erect a floating bridge, some 40ft. below low water, so that the largest vessels could pass over it, and to provide it with rails, acting as guides to a kind of floating ferry. The latter has a covered platform sufficiently high above water, so as to be beyond reach of the highest waves. On this platform the railway carriages are placed and thus carried from shore to shore. The ferry is propelled by means of a towing chain resting on the middle of the guide bridge and passing round a drum driven by steam on board the ferry. The passengers are not to be shut up in water-tight compartments and supplied with compressed air, as your worthy correspondent seems to imagine, but, on the contrary, would be able to enjoy not only the fresh sea air but daylight also.

I can quite believe that submerged guide bridges, similar to that proposed by my late brother and his friend, may one day prove to be a valuable addition to the existing modes of crossing the waters, and it would perhaps be worth a trial at some suitable

Digitized by Google

place. *A priori*, one would expect a submerged bridge, out of harm's reach, to be more durable than a pontoon bridge, of which there are many in existence.

In conclusion, I may mention that I do not intend entering into any lengthy discussion about the merits or demerits of my brother's proposal, but content myself with having drawn the attention to it, which it certainly deserves, even if only for its originality. Those readers of your valuable journal who have more than a passing interest in the matter I refer to an illustrated pamphlet, published by the inventors in 1874, under the title "The Channel Railroad Ferry," and printed by Messrs. Vacher & Sons, of 29, Parliament Street, London, where it may probably still be obtained.

Yours, &c.,
EUG. OBACH.

Woolwich, January 25th, 1890.

THE BAILEY-FRIEDRICH STEAM MOTOR.

WE give two views in Figs. 1 and 2, on the opposite page, a new steam motor which is being extensively made by Messrs. W. H. Bailey & Co., Limited, of Salford. The machine is complete with boiler, which forms a base for the engine. The boiler consists of a number of Field tubes fixed into a steel plate, which is suspended, by means of steel bolts, from an upper plate of the same material. The coal is fed by the hopper shown, and moves slowly upon the fire-bars, which are angularly placed. It is found that the emission of black smoke is prevented, owing to the gases passing over the coked fuel at the back of the fire. A heavy charge can be put into the hopper, and this slowly falls on to the bars. An interval of an hour may occur between the charges. Owing to the peculiar construction of the boiler—no rivets being employed—it is easily repaired, and if the pressure rises much higher than the fixed amount—viz., 70lb.—the expansion of the steel tube plates causes leakage, and thus renders the boiler inexplosible. Also, by an ingenious arrangement, a flap over the air door, placed at the top of the hopper, is opened or closed if the steam falls below or rises above the normal pressure, thus automatically regulating the combustion. The engine is, as shown, of an ordinary vertical kind, and is controlled by a sensitive governor of the high-speed type. The governor sleeve has a cam groove formed in it by means of which an automatic rotary cut-off valve is regulated. By means of a screw valve the supply of steam can be accurately regulated, and the cut-off arranged as desired.

The chief feature of this motor is, however, to be found in the treatment of the exhaust steam. There is a surface condenser fixed in a vertical position, round the tubes of which a continuous current of water is passed. The water supply is obtained from a tank or cistern similar to those used with gas engines for supplying the water jacket, so that the water can be used over again, with occasional replenishments to compensate for the slight loss by evaporation, which, however, is not great. After the engine has been working for some short time, the water becomes of a temperature of 100° to 150° Fahr., and it is found that a considerable mineral deposition takes place where salts exist in the water. The steam being condensed, the water so obtained is pumped back into the boiler, and it is found possible to maintain an unvarying water line in the boiler. The same water is used repeatedly, and if it were not for the slight loss resulting from escapes of steam through the stuffing boxes, &c., there would practically be no fresh water needed. It has been established by experience that about two quarts of water per horse-power per day is all that is necessary to supply all loss in the engine or boiler. This quantity is obtained from the condenser by means of a sight drop feed, the rate of the dropping being regulated by a valve. In this way the feed water is kept pure, and incrustation of the tubes prevented. The small consumption of water is remarkable, but is verified by a large number of users in various parts of the world. If necessary the boiler can be arranged to burn petroleum, the consumption being about one quart per horse-power per hour. The makers have not hitherto made many of these motors for this country, but have sent a large number abroad. They have made several in combination with dynamos, including one for the Thomson-Houston Company. A motor has also been sent to the Williamson Electric Company, of Sydney, of which Mr. Williamson, late superintending engineer for the Edison Swan Electric Light Company, of Manchester, is the founder. The motor has also been applied to pumping, and, generally, there have been a number of combinations made. Messrs. Bailey have given some results of a number of daily tests made at their works with a motor supplying power for 40 16 c.p. incandescent lamps, the fuel used being gas coke. The fire was lighted at 3 p.m. each day, and the current finally switched off at 9 p.m., during which time the fuel used was 135lb., the cost being 6d. per cwt., or equal to 1d. per hour. This is a remarkable result, and one probably the makers would not guarantee, but if it is even approached should be of sufficient importance to justify the adoption of the motor for small powers. The motor is made in three sizes, developing respectively 4, 8, and 12 brake horse-power.

INSTITUTION OF ELECTRICAL ENGINEERS.

ON the 23rd inst. the discussion on the President's address on "Magnetism" was continued by

Mr. Shelford Bidwell, who referred to the portion of the paper relating to the influence of stress on magnetisation. If a long thin iron wire be suspended vertically and subjected to longitudinal magnetising forces, its curve of magnetisation, resembling Fig. 1, is easily obtained. If now the wire is stretched by a weight, the curve of magnetisation rises more rapidly at first, but subsequently bends over and cuts the ordinary curve, and remains below it as the magnetising force increases. The point of intersection is known as the "Villari critical point," and the change in the relative permeability is called the "Villari reversal." Converse effects were obtained by Joule in 1840, who showed that a bar is lengthened by magnetisation until the magnetising force reaches about 120 c.g.s. units when no further elongation was observed. Some time ago he had misunderstood Prof. J. J. Thomson's argument, for quite recently the latter had predicted a "Villari reversal" when cobalt was compressed, and this was verified by experiment, whereas he had published a contrary prediction.

Prof. Roberts-Austen said that even pure electro-deposited wrought iron on cooling does not evolve heat as carbonised irons do at 858° C. Osmond has, however, shown that there are at least two perfectly distinct phenomena which may be observed in cooling masses of iron. First, there was the transformation of hard β iron into soft, or α iron; and secondly, the "recalescence" of Barrett. Heat is evolved at both points, but the first is variable in position according to the chemical composition of the mass, and is that at which the magnetism reappears. The second point, the true recalescence, occurs at a fairly constant temperature of about 640° C., and it has, Prof. Austen considered, no appreciable effect on the magnetic properties of the mass, but is essentially due to a change in the relations between the carbon and the iron.

Professor S. P. Thompson said the behaviour of the nickel-iron alloy reminded him of a specimen of natural alloy of the same two metals shown to him some years ago by M. Becquerel. This differed in its magnetic properties from Dr. Hopkinson's samples, for although it was non-magnetic when first obtained, it became magnetic on being heated and allowed to cool. Dr. Thompson said that, in a paper on the Mechanism of Magnetisation, Chivolson had endeavoured to distinguish between temporary and subpermanent magnetism, and his curves show that the former increases regularly at first, and afterwards more slowly, whilst the latter makes a sudden rise when the magnetising force reaches a certain value, and afterwards remains nearly constant as the force increases. The sum of the two effects gives the usual magnetisation curve. The speaker also described a simple apparatus for measuring permeability by measuring the attraction due to the induction over the cross-section of the sample.

Professor Ayrton asked Dr. Thompson whether the character of the surfaces in contact affected the results obtained by his new apparatus. He also inquired whether the President had tried if the magnetic properties of iron were regained at a white heat, for Dr. Wormwell said that such was the case. On roughly trying the experiment by heating a piece of iron in a blowpipe flame and bringing a magnet near it, he had only found one out of three pieces to give any signs of magnetisation, and of this he was not quite certain.

Mr. J. Swinburne, alluding to Weber's theory of magnetisation, inquired if any experiments had been made with the object of setting the axes of all the magnetic molecules parallel by first magnetising the sample at right angles, and thus reducing the angle of the cone within which, for a given magnetising force, they must all be. As a method of doing this, he suggested that a wire be subjected to circular and longitudinal magnetisation successively. Referring to the terminology of the subject, he said the term "magnetisation" generally conveyed very vague ideas to the average mind, and thought its use should be avoided.

Mr. W. H. Preece described the methods of testing magnet steel used by the Post Office authorities, and promised to add a table of tests to his remarks as printed in the Journal. The tests are made by two methods—1st, by determining the force required to detach an armature; and, 2nd, by the magnetometer method. A great improvement, he said, was made in the magnetic quality of steel by the addition of about 3 per cent. of tungsten, the influence of which was brought into prominent notice by the Alvarre steel exhibited at the Paris Exhibition in 1881. The subject, he thought, required the careful attention of manufacturers, and he hoped that immediate steps would be taken to improve the quality of magnet steel. On examining the numbers obtained by Continental observers, he found that the maximum value had been obtained by Kohlrausch, and was 3,900.

Mr. S. Evershed said he was one of those who thought there was no need to use the word magnetisation in its present ambiguous sense, and that the ideas of polarity, magnetic moment, free magnetism, &c., were not required, except, perhaps, for permanent magnets; even with them, now that the President had given a definite meaning to "coercive force," this value of H, together with the permeability, seemed to him to give all the necessary information. He also thought the word "induction" should be defined to mean what is generally called "total induction," and a new name should be given to density of induction, or induction per unit area.

Mr. A. P. Trotter asked the President whether the sample of nickel iron alloy, whose properties were represented in Fig. 11, was unique, or whether other alloys have been found to give similar results. The remarkable peculiarities of this specimen suggest the possibility of copper, lead, &c., being cooled low enough to become more magnetic than Mr. Preece's magnet steel.

The President, in replying to Sir W. Thomson's remarks on recalescence, said that in heating the metal a considerable absorption of heat occurs at about 30° C. above the temperature at which recalescence takes place on cooling, but his experiments proved that the changes in the magnetic properties follow precisely the absorption and liberation of heat both in ascending and descending. Referring to Professor Ewing's remarks on what he called the "hysteresis of nickel steel," shown in Fig. 11, Dr. Hopkinson said he thought the word hysteresis not very appropriate when applied to this phenomenon, for he considered the peculiarity more analogous to change of state from liquid to gas, or *vice versa*, as in the case of water, for example, these changes can be considerably retarded by adopting suitable precautions. Professor Roberts-Austen had, he said, alluded to the liberation of heat when iron changed from the non-magnetic to the magnetic state. The phenomena accompanying this change seemed to him (the President) to be analogous to "boiling with bubbling," where the temperature of the liquid is first raised considerably above the boiling point, and a sudden liberation of vapour brings down the temperature. As regards Professor Ayrton's question relating to the return of the magnetic property at high temperature, he could only say that he had not observed it, but the greatest temperature attained in his experiments was about 950° C. Referring to the revision of terminology by several speakers, Dr. Hopkinson thought there was no necessity for this, for the terms "pole," "magnetic moment," &c., were most convenient when talking of permanent magnets; whilst "induction" and "permeability" were preferable when the magnetisation of iron was under discussion. In reply to Mr. Trotter, he said that many other alloys had been tried, and one specimen of nickel-steel, containing 5 per cent. of nickel, gave very similar results to that shown in Fig. 11, but the range between the critical temperatures was considerably shorter, these temperatures being 650° C. and 800° C. respectively. The same sample tested for recalescence was found to absorb heat about 800° C., and on cooling heat was liberated about 650°, thus showing the close connection between these phenomena and magnetisability. Since last meeting he had tested the variation of specific resistance of nickel-steel with temperature, and found that a considerable reduction was produced by cooling it in solid carbonic acid. On heating its resistance increased slowly and uniformly at first, and afterwards with increasing velocity, until a temperature of 600° was reached. At this temperature a sudden change occurred, and the resistance increased more slowly and uniformly as the temperature rose. On cooling the specimen its resistance fell uniformly until at the ordinary temperature it returned to its initial value. The whole cycle could be repeated by again cooling in carbonic acid and proceeding as before. Fig. 6 shows diagrammatically the character of the changes. Other samples were tested for tensile strength, and when in the ordinary state gave an average breaking stress of 50 tons per square inch with an extension of 30 per cent. Specimens which had been chilled broke at 85 tons with an extension of only 8 per cent. This fact, he said, was of vast importance from an engineering point of view, for if such changes in the nature of a mild steel were brought about by its being subjected to a hard frost, the consequences would be very serious if such a metal were used in structures.

GRAPHIC CONSTRUCTIONS FOR DYNAMOS AND MOTORS.

BY PROFESSOR ROBERT H. SMITH.

III.

(*Continued from page* 91.)

Provided that k be not small as compared with R, then the external voltage ϵ changes very little with the external current a if the condition be fulfilled that $R\frac{\tau}{t}$ be only slightly greater than k. If $R\frac{\tau}{t}$ nearly equal k, then, of course, k must be much greater than R, because τ is always made much larger than t. Since this is a most important case, approximately constant voltage machines being more needed than any others, it is specially illustrated in Fig. 8. The approximately constant external voltage ϵ is only a little less than E_k. The variation of ϵ is less the flatter the $E\alpha/^1$ curve is beyond the point E_k. As k decreases with the speed, and starts from the value ρ at the first speed at which the machine begins to work, it is evident that, for every machine in which $\tau > t$ and $R\frac{\tau}{t} < \rho$, there is a theoretically possible velocity at which this result is obtained. In order to fulfil this condition, and at the same time obtain a high value for ϵ or E_k, it is necessary that $R\frac{\tau}{t}$ should not be large, which can be economically done only by making R, the internal resistance, very small.

In the other case, see Fig. 9, in which $R\frac{\tau}{t}$ is a little less than k, the same general variation of the quantities takes place so long as ϵ, the external voltage, lies below E_k. When $\epsilon = 0$, E is at its maximum, the machine being short-circuited between the terminals and there being no current in the shunt. As ϵ rises, E, A, and a all decrease as in the previous case. When $\epsilon = E_k$, the line $R\frac{\tau}{t}$ cuts the curve $E\alpha/^1$ at two places; the higher intersection, however, being the one that has a physical meaning, because it alone has physical continuity with the intersections obtained when ϵ was less than E_k. Still continuing the rise of ϵ, the higher of the two intersections, giving the corresponding E, still sinks and proceeds towards the left-hand. This continues until the line $R\frac{\tau}{t}$ becomes tangent to the curve E/α^1. At this position its lower end (or intersection with line ρ) gives the maximum possible value of ϵ. Continuing the left-hand movement of the intersection of the $R\frac{\tau}{t}$ line with the E/α^1 curve, the value of E still decreases, but ϵ now begins to decrease. At the same time $(E - \epsilon)$ continues to decrease as before, and therefore so also does A and a. Note that during this fall of ϵ, the intersection on the curve further to the right-hand has no physical meaning. It is thus evident that there is no ambiguity between these two intersections. The two belong to quite different values of A and a, and of, therefore, τ, the external resistance; these different values, however, corresponding to the same value of ϵ.

It is evidently by this arrangement that the nearest approach can be made to constant external voltage. Roughly speaking, this result is reached by making $R\frac{\tau}{t} = k$. As already mentioned, k can be made equal to a given value of $R\frac{\tau}{t}$ (within certain limits), by regulating the speed to make it so. But this is not the proper procedure. The speed should be settled among the first elements of the design in accordance with the energetic requirements to be fulfilled by the design. So also are settled the elements which fix the form of the curve E/α^1, and also R and ρ and τ (τ depending chiefly on the "efficiency" demanded). There remains, however, t undetermined by these more fundamental considerations. Therefore, the nearly constant external voltage is obtained by making $t = \frac{R}{k}\tau$.

Or, rather, t is to be made a little greater than this value. How much greater can be determined exactly with great ease by half of the diagram. The ends of the stretch of the E/α^1 curve to be used in ordinary working are first determined by considering the values of E required for the machine to work as may be desired in the two extreme cases of minimum and maximum resistance ever used. The slope of the chord joining these two points of the E/α^1 curve is to be used in the equation instead of k, and the number of turns thus determined for the series coils will give the greatest possible constancy to ϵ consistent with the other elements of the design already determined.

In motors compound wound, and with the series coils inside the shunt terminals, the value of α^1 for the E/α^1 curve remains the same as for generators—viz., $\alpha^1 = \alpha + A\frac{t}{\tau}$. But ϵ is now greater than E and $A = \frac{\epsilon - E}{R}$. A line from the point at the height ϵ on the ρ line (and therefore with horizontal ordinate α) to the point on the $E\alpha/^1$ curve at height E, slopes downwards to the right hand; that is, it has a negative tangent of inclination to the horizontal axis, this tangent being as before $\frac{\epsilon - E}{A\frac{t}{\tau}} = R\frac{\tau}{t}$. Fig. 10 illustrates the construction of the characteristics, internal and external. The parts of the curve E/α^1 and the line ρ below their intersection have evidently no application here, because throughout this part of the diagram no line can cross from a *higher* point on the ρ line with a *negative* slope to a *lower* point on the curve. All values of $R\frac{\tau}{t}$ used as a negative slope give possible results, the limiting case being again the pure shunt wound machine in which the line $R\frac{\tau}{t}$ is vertical.

It must be noted as one of the most remarkable distinctions between generator and motor working that in the motor it is not necessary that the initial slope of the E/α^1 curve should be greater than ρ, as was seen to be the case in generators. If it be less, the construction of Fig. 10 may be followed down to the origin where both ϵ and E become zero. If it be greater and the curve cross the ρ line at height E_k, this is the lowest value of ϵ and E_k at which the machine will work at that speed as a motor. At this limit $\epsilon = E$, and, therefore, no current passes through the armature; it all passes through the shunt coils. The shunt current magnetises the field so that at this speed the counter-electromotive force just balances the external positive voltage between the terminals. Since there is no armature current, there is no mechanical moment being driven and no horse-power being developed in the motor; it is running "empty" at the given speed. At this limit the external current equals the shunt current α. With a diminished external current the machine could be run as a generator in series with the other generator in order to reinforce its action

Digitized by Google

—of course, on the condition that mechanical power is *supplied* by the belt to drive it.

From Fig. 10 it will be noticed that after the armature current A has been found by placing $(\epsilon - E)$ under the R line, the external current a is found by *adding* a to A instead of subtracting, as in the case of the generator.

It should also be noted that the same machine run as a motor has an E/a^1 curve a little higher than it would be when the machine is run at the same speed as a generator, because for equal ampere-turns on the magnets the motor has the smaller armature current, and, therefore, also smaller armature self-induction and cross-magnetisation.

(To be continued.)

DOUBLE-POLE TWO-WAY SWITCH.

Our illustration shows a new form of switch, made by Messrs. Woodhouse & Rawson, which is likely to find favour with those who advocate the double-pole arrangement of switches. Its construction contains one or two interesting novelties. It will be seen that the brushes are built up in a somewhat different way from the well-known multiple brush hitherto employed in switches of Messrs. Woodhouse & Rawson. They are given a still greater individuality of movement by separating each part from the adjacent one with a washer in the centre, and for simplicity of construction they are made with square corners in place of round. The crossbars which connect the two brushes are of vulcanite, which possess sufficient strength and the necessary elasticity and insulating properties. The method of attachment for the cables is the very convenient movable socket form into which the cable is sweated. The switch appears to be well designed for a class of work which is in common demand.

NOTES ON ALLOYS.

I.

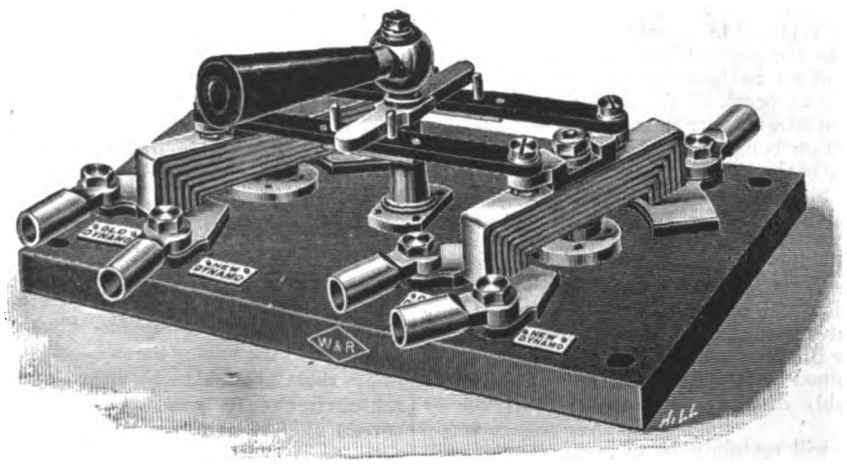
We propose reviewing from time to time the progress made in the manufacture of alloys or in their industrial application, but in this our first notice we do not intend to do more than briefly note the direction in which improvements are now being made, reserving for future descriptions details of the more important patents and developments as they are brought before the public.

By far the most interesting alloys from an industrial point of view are the special steels which have been introduced within the last year or two, and which have originated from the careful analyses of many chemists, who have shown that minute percentages of foreign elements have an important influence on the quality of the iron and steel containing them. Considerable attention has been devoted to these new steels in France, and several French manufacturers are now making these steels of definite composition and possessing definite physical qualities. They are known commercially under the names of manganese-steel, silicon-steel, chrome-steel, copper-steel, tungsten-steel, titanium-steel, and nickel-steel. We have in a recent article (see *Industries*, Vol. VII., page 526) drawn special attention to the last of these, and have there pointed out that the increase in the visible supply of nickel will no doubt tend to induce manufacturers to turn their attention to this remarkable alloy. We do not propose to discuss the merits of these other steel alloys, but refer the reader to the summary of their properties and composition as at present known to the appendix of Howe's treatise on "The Metallurgy of Steel," which has recently been published by *The Engineering and Mining Journal*. Visitors to the Paris Exhibition must have been struck with the specimens of ferro-chrome and chrome steel that were then exhibited, and noticed that Holtzer and the manufactory at Firminy have used these alloys to a considerable extent for the manufacture of projectiles and thin plates for protection against musketry. Chrome steel is also used for the manufacture of files and other cutting instruments. Most of this chrome steel is at present made in crucibles, although some French makers have adopted the basic open-hearth furnace with success.

The establishment of the manufacture of aluminium on a sound commercial basis has also given an incentive to the study of the alloys of this metal, and has introduced into the market a series of copper-aluminium alloys which are competing with the older brasses and bronzes. These alloys, varying in content of aluminium from 12 to 2 per cent., differ widely in their physical properties, and seem to have a wide future before them. The alloy containing the smallest percentage of aluminium has been used by Christoffle in Paris for many years for casting models of works of art, while those containing a larger quantity of aluminium are in use for bells, musical instruments, and as a substitute for gold; and that with 10 per cent. of aluminium has a hardness, ductility, and elasticity equivalent to that of the best kinds of steel. An admirable *résumé* of our present knowledge of these aluminium bronzes has been contributed to a recent number of Dr. O. Witt's new journal *Prometheus* by D. E. Heim.

In the manufacture of alloys, as is well known, great care is required to prevent the oxidation of the more oxidisable metal present, and also to avoid the introduction of foreign elements which may deteriorate the quality of the metal produced. Many ingenious patents are continually being applied for to cover these difficulties, and we shall hope to discuss them as they come before us from time to time. Brin, in a patent last year for the manufacture of the triple alloy of copper, iron, and aluminium, has claimed the use of an atmosphere of aluminium chloride, or a mixture yielding the same to avoid the loss of metal by oxidation, and as an illustration of methods for the removal of foreign elements from alloys we may cite what appears to be a valuable patent of Professor Roberts-Austen and others, who claim to purify the alloys of iron from sulphur by treating the molten metal with an alkaline mixture containing a cyanide or cyanogen compound. With these rapid strides in the manufacture and application of new alloys little has been done towards contributing to our knowledge of the chemical composition of these important bodies, but we should think that with the increase of data now obtained further research will before long formulate a theory which will generalise our present empirical data in a way which will be the means of indicating the direction in which future fresh discoveries may be made. We drew attention some time past to a communication by Mr. A. P. Laurie on the constitution of the copper tin alloys, and he has recently communicated to the Chemical Society the results of a further investigation on the constitution of alloys. It appears from these experiments that the electrometer method confirms the conclusions arrived at by Matthiessen, that lead, tin, zinc, and cadmium do not combine with each other when mixed together. It will be remembered that in his earlier paper the author pointed out that from the behaviour of copper-zinc and copper-tin alloys in a voltaic cell it is evident that compounds of the formulæ Cu_2Sn and Zn_2Cu exist in these two alloys. The text-books usually give the formula Sn_3Pb for the lead-tin alloy, but the author finds that the composition of the alloy, as well as its electrical behaviour, does not warrant this statement, and Spring, in a recent paper, states that he does not believe that these metals form a compound. The usefulness of the lead-tin alloys for wiping a joint is owing to their behaviour on cooling, one alloy apparently crystallising out after another, so that they remain in a pasty state for a considerable range of temperature.

THE EXAMINATION OF COMMERCIAL GLYCERINE.



In the United States a different import duty is imposed on crude and refined glycerines, which renders it necessary for the United States Laboratory to analyse every import of crude glycerine, in order to prevent possible attempts to enter through the Custom House a partially refined glycerine as the crude article. Mr. Wainwright, in a recent article published in the journal of the American Chemical Society, after reviewing the methods at present adopted for deciding this point, advocates the use of the following tests as extremely reliable and admitting of very nice distinction between crude and refined (or distilled) glycerine, which may be valuable to buyers of glycerine in this country. A 10-grm. sample is heated in a tared platinum capsule until it inflames, when the source of heat is removed, and it is allowed to burn spontaneously. Distilled or refined glycerine will yield from 0 to 0·5 per cent. of carbonaceous residue, rarely more than 0·5, and never as much as 1 per cent., whereas crude glycerine frequently yields as high as 10 per cent. The ash may be determined by igniting this carbonaceous residue, but he points out that Sulman and Berry's conclusions on the value of the ash determination will not apply to a crude glycerine which has been made by the saponification of fats with steam. He also advocates the use of the silver nitrate and basic lead acetate tests, which he uses as follows:—5 c.c. of the sample is dissolved in 20 c.c. of distilled water, and 5 c.c. of a 2 per cent. solution of silver nitrate is added, and the mixture allowed to stand at rest for an hour. Crude glycerines give a flocculent precipitate, while refined glycerines give a darkening of the solution accompanied with a slight reduction of silver. The lead acetate test consists in adding to a basic solution (made by adding 10 grms. lead acetate, 8 grms. litharge, to 500 c.c. distilled water, then boiling and filtering) its own volume of a solution containing equal volumes of the sample and distilled water, and shaking and allowing to stand at rest for one hour, as in the silver test. Refined glycerine remains unchanged, whilst crude glycerine will always give more or less of a flocculent precipitate. Refined glycerine should also give no reaction with ammonia, ammonium oxalate, barium chloride, nitrogen peroxide (gas), or Fehling's solution, whilst crude glycerine often responds to these tests.

THE ESTIMATION OF OXYGEN DISSOLVED IN WATER.

Dr. Thresh, in a recent communication to the London Chemical Society, has described an entirely new process for estimating the oxygen dissolved in water, which is of great simplicity, and apparently gives as accurate results as the elaborate method used by Schützenberger, and subsequently modified by Dupré and Dibdin, Roscoe and others. The process is based on the observation that whereas, in absence of oxygen, nitrous acid and hydrogen iodide interact to form iodine, water, and nitric oxide; in presence of oxygen the nitric oxide becomes reoxidised, and, serving as a carrier of the oxygen, an amount of iodine equivalent to the oxygen present is liberated, in addition to that resulting from the initial action of the nitrous acid. The solutions employed are (1) a solution containing ·5 gram sodium nitrite and 20 grams potassium iodide in 100 c.c.; (2) a solution of 7·75 grams sodium thiosulphate (hyposulphite) in 1 litre, 1 c.c. of which corresponds to 0·25 milligram of oxygen; and (3) a solution of starch and (4) dilute sulphuric acid (1:3). The apparatus consists of a wide-mouthed glass bottle of about 500 c.c. capacity, fitted with a four-holed india-rubber cork. Through one of these holes is fitted a separator, containing the water to be

DOUBLE-POLE TWO-WAY SWITCH.

Constructed by Messrs. Woodhouse & Rawson, London.

Digitized by Google

examined and 1 c.c. of the nitrite iodide and 1 c.c. of the acid solution, while through a second hole passes a glass tube fitted to a burette containing the standard th osulphate solution. The third and fourth holes contain inlet and exit tubes for coal gas, which is introduced into the bottle for some time before the experiment in order that all the air in the apparatus may be expelled. After fifteen minutes have elapsed the stopper of the separator is removed and is replaced by a cork fitted with an india-rubber tubing to the gas exit tube in the bottle, which prevents access of air to the water as it flows into the bottle when the stopcock of the separator is opened. The water is then titrated with the thiosulphate solution, the starch solution being added through the separator when the colour of the iodine is nearly destroyed. Concordant results are easily obtained by this process, and the author has found that the small quantity of oxygen present in coal gas does not interfere with the accuracy of the method. By previous blank experiments, and allowing for the effect of the oxygen in the thiosulphate on the assumption that as much oxygen is dissolved in it as distilled water would contain at the same temperature, the author has obtained results which closely agree with those obtained by Roscoe and Lunt for the oxygen content of freshly distilled water at different temperatures.

The method will certainly be of great value for determining the quantity of oxygen present in river waters and sewage by those chemists who have only occasionally to make this determination, and also in those cases in which it is desirable to make an examination of the quality of a water immediately the sample is taken, as the apparatus can easily be removed and fitted up at short notice.

Notes.

STANDARD SMALL SCREW THREAD,

The Electrical Section of the London Chamber of Commerce has appointed a small committee to push the adoption of the British Association threads.

EXCHANGE OF INFORMATION.

Mr. R. E. Crompton is anxious to arrange that the various electrical supply companies should exchange information as to costs of working. The Electrical Section of the Chamber of Commerce will, it is hoped, bring this useful exchange about, not only with reference to supply, but to other branches of electrical business and manufacture.

A NEW CANAL IN HUNGARY.

Her Majesty's Consul-General at Budapest has sent to the Foreign Office the conditions on which the Hungarian Minister of Commerce applies for tenders for the construction of a navigable canal near the Iron Gates of the Danube, and for the removal of obstructions in the river, and for other works connected with these undertakings. For the canal and some of the other works tenders are to be sent in by March 31st, while tenders for methods of, and apparatus for, blasting were to be sent in before to-day. Forms of tenders in German and Hungarian can be seen, and further information obtained, by personal application at the Commercial Department of the Foreign Office.

THE ESTIMATION OF PHOSPHORUS IN IRON AND STEEL.

Mr. Norris has modified the method recently proposed by Dr. Drown, in the journal of the American Institute of Mining Engineers, which renders it much superior to and more rapid than the Emmerton process usually adopted. The following is an outline of the process :—Five grams of pig iron or steel are treated in a large covered beaker with 90 c.c. of nitric acid (s.g. 1·135) for steels, or 120 c.c. for pig irons. After heating on an iron plate until all action ceases, and the solution begins to boil, 20 c.c. of a solution of potassium permanganate containing 8 grams to the litre are added. After boiling for a few minutes, a precipitate of manganese dioxide appears, indicating that excess of permanganate has been added A small crystal of tartaric acid is next added to dissolve the manganese dioxide which has been thrown down, and the solution transferred to a half-litre spherical flask, and 10 c.c. of nitric acid (s.g. 1·40) is added. The solution has then a volume of about 90 c.c., but in the case of pig iron the solution is first made up to 100 c.c. with water, the graphite filtered off, and 80 c.c. of the filtrate is treated with the 10 c.c. of nitric acid. The solution is then heated to 90° C., and 80 c.c. of ammonium molybdate solution added, the flask stoppered, wrapped in a cloth, and agitated for five minutes. The precipitate is then reduced with zinc, and titrated with permanganate, as in Emmerton's process. The molybdate solution is prepared from 100 grams of molybdic acid dissolved in 400 c.c. of strong ammonia, and then mixed with 1,200 c.c. of nitric acid (s.g. 1·20).

APPLICATION OF ELECTRICITY TO TRAMWAYS.

It is said that Edison has prophesied that in twenty-five years electricity will in great part have displaced horses, and it looks as if that prophecy was likely to be fulfilled. In Scranton, Pennsylvania, electricity has almost banished animal power from the street railways. The People's Street Railroad Company, which now works all the lines in the city, has twenty-five miles of railway under its charge, and the whole arrangement is found to work in a very satisfactory manner, as the cars run very smoothly, and do not experience any difficulty in climbing the steepest gradient. In the United States there are said to be 600 miles of electric tram and railway track in daily use, and on the Continent there are several electric tram lines in operation. In this country, however, comparatively little progress has been made, although there are now signs that the purely experimental stages are past. The few instances which have been carried out are the short railways at Brighton, Blackpool, and Portrush, and the recently inaugurated electric tramcars at Northfleet, and those on the Barking line of the North Metropolitan Tramway Company.

ARTIFICIAL MANURES.

According to *Kuhlow's*, the convention among the artificial manure manufactures has been very disadvantageous to the German agriculturists. This is especially marked in the ground Thomas slag trade, as the expiration of the contract with the German Agricultural Society was followed by a considerable rise in the price of that article. At the end of 1887, under the contract, the price per 1,000 kilos. had been fixed at 310 marks, while at the end of last year 510 marks was the price demanded. The manufacturers, by selling their slag meal to foreign countries at abnormally low prices, have been enabled to keep up the high prices in their home market. Phosphoric acid has also advanced in price, and last year in Germany it amounted to 80 per cent. increase on the former year. The artificial manure consumers have therefore been advised to buy from England and Belgium, where these products are far cheaper, and we understand that several contracts have been made for supplying Germany with Thomas slag meal from this country. Our competition in Germany will therefore be to the advantage of the German farmer, and probably result in the manufacturers restoring their prices to a fair level.

MACHINERY FOR CLEANING COAL.

This subject has been inquired into by a Committee of the Mining Institute of Scotland, and visits have been paid to numerous collieries in England and Scotland. The Committee has reported, and gives an account of the machinery in use at each of the places visited, but, with the proverbial caution of Scotchmen, do not commit themselves to a statement as to which of the systems is the best. They say what they saw, and leave the selection to the reader of the report. The following general deductions are made :—In the first place, the methods and appliances most suitable depend very largely upon local circumstances. The best results are obtained where attention is paid to the form of hutch and tumbler, the inclination of screens, and the drop into waggons. The best contrivance for screening where a large output has to be dealt with is the single or double jigger, or shaking machine, going at about 100 strokes per minute. For picking a shaking screen, or the travelling band, or both combined, is more economical. The dry process is universally employed for round coal—say above 1¼in. cube—and can be successfully applied to nuts from ¾in. upwards, where the refuse does not exceed 2, 3, or even 4 per cent. In the wet process, it is desirable to have the arrangement so that the small coal can be delivered direct from the screens into the washing tanks without the intervention of waggons. Where the coal and the refuse approach each other in specific gravity, the trough washer gives the best results. The felspar washer is the most effective for removing refuse from the smaller sizes—say under ¾in. The Robinson washer is cheap as regards first cost and up-keep, and requires little water, but a good deal of attention. Generally speaking, more elaborate machinery is effective in avoiding waste in preportion to its cost.

SULPHUR COMPOUNDS IN CRUDE PETROLEUM.

In the last number of the *Ber. d. deutsch Chem. Gesellschaft* Charles F. Mabery and Albert W. Smith have contributed a note on the results of their investigation on the sulphur compounds of the crude petroleum from the Ohio oil field. They find that on fractionating the crude oil, the sulphur compounds collect in the portion boiling between 200° and 300° C., and that they can be easily separated from this fraction by the addition of concentrated sulphuric acid. From this acid solution, after neutralising with lead carbonate or lime, the compounds separate on warming. They appear to be very unstable, but when the aqueous solution is distilled, a yellow oil collects in the distillate, which contains 14·97 per cent. of sulphur. When they attempted to distil the oil, it decomposed, evolving sulphuretted hydrogen. Under diminished pressure the oil was fractionated into portions, which, on being tested, contained no thiophene or mercaptan compounds, but consisted of various organic sulphides. The portions having the lowest boiling point yielded on distillation a hydrocarbon which formed a bromine addition compound of the formula $C_{17}H_{14}Br_2$. By the addition of alcoholic mercuric chloride they also succeeded in isolating the double compounds of methyl, ethyl, and propyl sulphides, and obtained indications of the presence of buryl sulphide.

SEMI-JUBILEE OF A GLASGOW LOCOMOTIVE FIRM.

The semi-jubilee of Messrs. Dubs & Co.'s Glasgow Locomotive Works took place recently, the works having been started in 1864. During the interval the firm had sent out 2,500 engines, and these are running in every part of the world, and by their working showed that Dubs & Co. turned out work which was second to none of its kind. Measured by the number of men employed, Messrs. Dubs & Co. now hold the second position in the kingdom among locomotive builders. In the month of September last the following were the number of employés in the leading establishments in Great Britain :—

Neilson & Co., Glasgow	2,166
Dubs & Co., Glasgow	1,744
Beyer, Peacock, & Co., Manchester	1,735
Sharp, Stewart, & Co., Glasgow	1,330
Kitson & Co., Leeds	1,260
Vulcan Foundry Co., Newton-le-Willows	538
Nasmyth, Wilson, & Co., Patricroft	518
Manning, Wardle, & Co., Leeds	389
R. Stephenson & Co., Newcastle	300
Hunslet Engine Co., Leeds	286

BUTTER SHOWS.

A very interesting series of butter shows has been organised at Copenhagen, by Professor Fjord, the well-known director of the Dairy Section of the Danish Agricultural Department, the first of which was opened on the 18th of November last. It appears that the shows hitherto held had not been of much practical benefit, and with a view to maintaining the position of that country as a producer of first-class butter, and effectually tracing to their source any faults in manufacture, an entirely new system of shows has been started, in which a large number of dairies, dairy experts, and leading butter merchants of Copenhagen and the provinces will co-operate in endeavouring to advance the general interests. It is expected that the evidence and practical information thus collected can hardly fail to be most instructive to all concerned. In the printed prospectus, setting forth the aim and general arrangement of these shows, Professor Fjord states that, while in many of the countries with which Denmark has to compete the most strenuous efforts are being made to improve and develop the yield of butter, the produce of his country has not gained in quality by the rapid increase in the number of associated dairies, whose members, he says, are often not competent to look after the important interests entrusted to them. Complaints, it seems, are not unfrequently heard of want of good keeping qualities and presence of water in butter; and now that the export of this article has become one of the principal sources of the country's income, it is held to be of the utmost importance that every means should be taken to maintain the acknowledged position which it has acquired in the markets of the world.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents).")

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

13th January, 1890.

570. Roots, J. ..... Rotary engines.
580. Brown, A. G. ..... Compound engines.
583-4. Tosh, G. ..... Rolling mill.
585. Meredith, T. ..... Type-writing machines.
592. Honegger, J. ..... Carding engines.
603. Asbeck, W. ..... Friction coupling.
606. Brock & Minton ..... Filter presses.
609. Priestman, Priestman, & Morgan ..... Dredging or lifting machinery.
614. Hood, J. ..... Wheel gearing.
619. Haddan, R. ..... Axle boxes (*Dory*).

14th January, 1890.

624. Eccles, R. ..... Looms.
628. Sloan, R. A. ..... Switches for railways (*Norton*).
629. Moore, B. R. ..... Street car motors.
631. Hartley & Wilson ..... Shuttle boxes.
645. Thornycroft, J. I. ..... Steam generators.
647. Dodge, M. B. ..... Crushing mills.
649. Dodge, M. B. ..... Rock breakers.
650. Dow, G. E. ..... Multiplex pumps.
655. Hall, R. ..... Ordnance.
662. Southgate, T. ..... Breechloading small arms.
666. Bonnard, J. B. ..... Apparatus for cleaning grain.
668. Rigby & Wylde ..... Apparatus for separating solids and liquids.
671. Clark, A. M. ..... Cutting stone (*Foerster*).
672. Wilkinson & Hague ..... Machines for tunnelling.
673. Von Babo, A. ..... Transmitting power.
676. Apostoloff, L. ..... Elevator for fluids and solids.
677. Rawsthorne, T. ..... Carding engines.
680. Maxim, H. S. ..... Armour-piercing projectiles and shells.
684. Crossley, F. W. ..... Gas engines.
685. Simon, Parkinson, & Parkinson ..... Apparatus for treating grain.
686. Mewburn, J. C. ..... Implements for imparting rotary motion (*Low*).
687. Mewburn, J. C. ..... Combination implements (*Low*).
697. Lake, H. H. ..... Looms (*Stafford*).
699. Lake, H. H. ..... Milling machines (*Woodruff*).
700. Lake, H. H. ..... Crushing machines (*Krom*).
704. Colvin, R. J. ..... Rail joints.
706. Scaife, W. L. ..... Lock gates and dams.
707. Lawson, G. ..... Machines for cutting rock.

15th January, 1890.

712. Greaves, W. McG. ..... Furnaces.
728. Bergmann, T. ..... Firearms.
729. Bergmann, T. ..... Locks for firearms.
731. Clifford, W. ..... Pressure gauges.
732. Brown, B. ..... Boiler flues.
739. Bartlett, C. H. ..... Weighing apparatus.
740. Clark, W. G. ..... Watertight ports and scuttles (*Clark*).
743. Feather & Greenwood ..... Hank dyeing machine.
745. Greaves, W. McG. ..... Furnaces.
749. Pritchard, J. ..... Cast iron mould.
752. Austin, H. K. ..... Dust shields for rolling stock and machinery.
753. Healey, Milne, & Healey Reeling machines.
754. Healey, Milne, & Healey Swifts for reeling machines.
757. Rogers, W. H. ..... Axles.
758. Wingen, A. ..... Combined hydrant and sluice valve.
766. Michaud, J. ..... Printing machine.
774. Jones, D. ..... Securing tubes in plates.
780. Emery & Brigham ..... Anti-friction devices for car axles.
785. Chance Brothers & Co., & E. F. Chance ..... Machinery for rolling glass.
787. Scott, A. E. ..... Rail for railways.

16th January, 1890.

799. MacLellan, J. A. ..... Moulds for casting.
801. Blance, R. P. ..... Propellers.
810. Schofield, H. ..... Glands of piston rods.
811. Truswell, W. ..... Furnaces.
813. Imray, H. ..... Rolling metal bars (*Moerchen*).
814. Allison, H. J. ..... Printing machines (*Morris, Gould, Fairchild, & Roberson*).
818. Fortune & Bentham ..... Drilling and punching machinery.
822. Tetlow, H. ..... Textile machinery.
823. Barlow, H. B. ..... Spinning machines (*Scott*).
824. Krause, G. M. ..... Gas engines.
825. Albert, W. ..... Machines for drying textile materials.
826. Muncaster, H. ..... Balanced slide valves.
832. Hope, G. F. W. ..... Sand separators.
835. Thomson, T. ..... Dams for retaining water.
837. Mannesmann & Mannesmann ..... Transmitting power.
838. Mannesmann, R. ..... Composite guns.
839. Mannesmann & Mannesmann ..... Driving shafts.
840. Mannesmann, R. ..... Metal furnaces.
841. Mannesmann, R. ..... Feeding and mixing metal in furnaces.
842. Mannesmann, M. ..... Fire bars.
843. Mudgemarchant, R. ..... Fluid-pressure engines.
856. Kluge, A. ..... Crank shafts.
861. Harfield, W. H. ..... Steering gear for ships.

17th January, 1890.

870. Garrett, G. W. ..... Vapour engines.
876. Darling & Darling ..... Brake.
877. Elliott, D. ..... Furnaces for heating iron.
883. Skett, M. ..... Breechloading small arms.
886. Ogden, J. E. L. ..... Metallic packing.
894. Mewburn, J. C. ..... Air-compressing machines (*Proell & Kummel*).
908. Thoms, W. A. ..... Drawn or rolled metal articles.
909. Morgan, W. M. ..... Elevated railways.
912. Horn, W. W. ..... Piston rod packing (*Grob*).
916. Ballard & Fisher ..... Railroad scales.
917. De Rechter, F. ..... Railway vehicles.

18th January, 1890.

922. Holden & Ashworth ..... Machinery for winding yarns.
927. Pilkington, W. W. ..... Glass annealing kilns.
928. Tweedale, S. ..... Carding engines.
930. Bradbury & Tonge ..... Looms.
931. Kendal, G. C. ..... Boiler furnaces.
935. Austin, H. K. ..... Axle boxes.
943. Wise, W. L. ..... Steam plows (*Brown*).
947. Urry, E. C. ..... Steam engines.
948. Howard, T. H. ..... Ordnance.
952. Grimston, G. S. ..... Oil burners for furnaces.
953. Hart & Baynes ..... Carding engines.
958. Ferrière, L. Le G. ..... Rotary engines.
959. Davy, C. ..... Pumping engines of presses.
960. Saunderson, H. P. ..... Machines for cleaning corn.

ELECTRICITY.

13th January, 1890.

600. Mewburn, J. C. ..... Dynamo-electric machines (*Carriere*).
607. Peacock & Langb ..... Electric motors.
615. Evered & Rudling ..... Electric lighting.

14th January, 1890.

665. Crampton, P. J. R. ..... Electric motors.
693. Currie, S. C. C. ..... Electric motors.
694. Clegg, J. ..... Electric lamps.

15th January, 1890.

718. Nichols, A. E. ..... Electric lamp holders.
761. Dahl, O. ..... Electric batteries. (17th June, 1889.)
771. Oesterreich & Genest ... Telephone system.

16th January, 1890.

804. Gardner, W. J. ..... Electric brake.
836. Gwosdepf & Bunge ..... Telephonic circuits.
847. Graham & Allen ..... Electrical communicators.

17th January, 1890.

872. Perry, J. ..... Alternating dynamo.
873. Perry, J. ..... Electric supply meters.
878. Swinburne, J. ..... Dynamo machines for producing electric energy, ventilation of culverts for distributing it, accumulators for storing it, and motors for utilising it.
882. Patterson, G. W. L. ..... Linesman's detectors.
911. Pitt, S. ..... Insulating conductors (*Atherton*).

18th January, 1890.

941. Lineff & Bayley ..... Electric tramways.
950. Thompson, W. ..... Dynamo machines.
962. Swinburne, J. ..... Cars worked by accumulators.

CHEMISTRY.

13th January, 1890.

575. Ginster, M. C. ..... Manufacturing manure.

14th January, 1890.

656. Templeman, J. ..... Soaps.
670. Domeier, A. ..... Purifying salt (*Mitting*).

15th January, 1890.

715. Wolseley & Punshon ... Explosive compounds.
724. Hummel, J. J. ..... Red dye.
735. Bang, A. ..... Dyestuffs (*Dahl & Co.*).
764. Barnes, W. H. ..... Paints.
779. Leigh, H. H. ..... Alumina and phosphoric acid (*Lorenzen, Stuhr, & Heinz*).
788. Horn, W. W. ..... Washing gas (*Jarrell*).
792. Guignard & Hédouin ... Alcohol.
794. Maxim & Sedgwick ..... Carburetting gas.

16th January, 1890.

858. Roth, C. ..... Ammonium and sodium salts.
859. White, W. ..... Aluminium.

17th January, 1890.

907. Thoms, W. A. ..... Electro-deposition of alloys.
910. Freund, E. ..... Manufacture of gas.

18th January, 1890.

933. Feld, W. ..... Caustic soda.
938. Lewis, G. H. ..... Distributing oil on waves (*Banzett*).

MISCELLANEOUS.

13th January, 1890.

574. Garniss, F. ..... Spindles.
598. Wynne & Morrison ..... Dry gas meters.
618. Smith, W. E. ..... Alarm signalling.

14th January, 1890.

643. Tullis, J. K. ..... Leather belting.
679. Lockwood, C. S. ..... Belt fasteners.
703. Haddan, R. ..... Dyeing textile materials (*Leplat*).

15th January, 1890.

711. Greaves, W. McG. ..... Ventilator.
768. Teuber, C. ..... Fire escape.
769. Dunn, M. ..... Fire escapes.

16th January, 1890.

800. Tarbath, H. ..... Fire escapes.
864. Lorrain, J. G. ..... Extinguishing fire.
865. Lorrain, J. G. ..... Saving life from fire.
866. Duncan & McLaren ..... Miners' safety lamps.
869. Ball, J. ..... Deep-sea trawling gear.

17th January, 1890.

880. Foster, R. ..... Marine signalling.
893. Ford, A. N. ..... Insulating and waterproofing composition.
903. Charles, E. ..... Vats for dyeing.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1888.

14901. Dougherty.
16486. King.
17220. Jones.
18211. Vaughan (*Weiller*).
18357. Herbert.

1889.

489. Myall (*Judd*).
598. Fisher.
813. Diehl.
935. Leeming & Wilkinson.
954. Capell.
1013. Craig.
1046. Willcox (*The Farbenfabriken vormals Friedrich Bayer & Co.*).

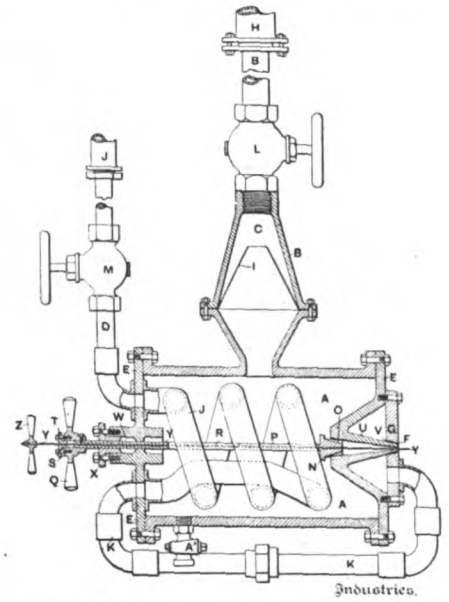
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.



ENGINEERING.

Wire Ropes.—*E. E. Bird, London.*—This improvement consists in making wire ropes of an elliptical section. In such a rope greater flexibility is gained in comparison to its strength than if the rope was circular, and from the fact that the rope will bend in the direction of its greatest flexibility the tendency to revolve will be obviated. Claims: (1) The manufacture of a core for a wire rope, band, or cable, of an elliptical or oblong shape, having its major diameter in the same plane throughout its entire length; (2) the drawing of a core through a tube, or through a collar, and between a pair of rollers, to ensure its major diameter being in the same plane throughout its entire length; (3) the manufacture of wire rope, band, or cable, of an elliptical or oblong shape, or as nearly as possible elliptical or oblong as is consistent with the ropes laid or twisted round a core, and having its major diameter in one and the same plane throughout its entire length.—No. 2464. February 12th, 1889.

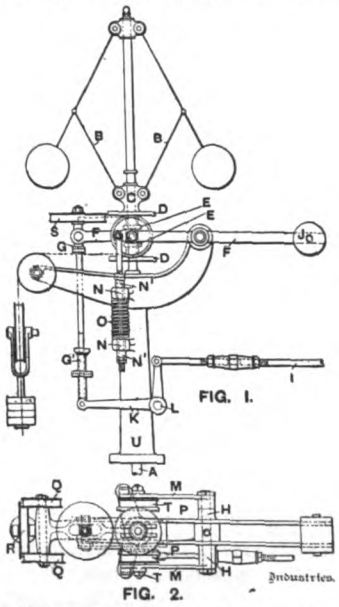
Bending Plates.—*D. R. Radcliff, London, & J. M. Garvey, Liverpool.*—The machine here described enables the plates to be bent to the required shape without removal from the bending table. A suitable cylinder or shaft of metal, turning on journals, is mounted upon bearings on the bending table. From this cylinder a fourth is removed, the part removed being such as would be contained by two planes passing through the axis of the cylinder at right angles to each other. Another part of the cylinder similar to that removed is detached from the rest, but held in position by being bolted to eccentric plates, which are mounted on the journals of the cylinder. The eccentric plates hold the detached portion, which constitutes the former, in its original position, and they are connected to the main portion of the cylinder by catches. The face of the detached part or former nearest the cylinder is reduced to permit the plates to be bent being passed between the two. The surface of the bending table is level with and projects to the centre of the cylinder. The operation of the machine is as follows:—The plate is passed along the bending table into the slit between the former and the cylinder until the point at which it is be bent is at the centre of the cylinder. The cylinder and former are now revolved together, and the plate being held between the two is bent on the edge of the table at the centre of the cylinder. When the plate has been bent the cylinder is released from the former by the catches, and the cylinder thus assumes its original position by revolving backwards upon its journals. As the cylinder revolves backwards the eccentric plates cause the former to be raised, and so enable the plate bent to be easily removed. Four claims are made.—No. 17,362. November 1st, 1889. 8*d.*

Lubricators.—*E. D. Bangs, Milwaukee, U.S.A.*—The lubricator here described is intended for those parts of engines which have reciprocating motion. The body, or container, for the lubricant is of cylindrical shape. In a thickened portion of the side of the container is made a small vertical channel which extends from within and at the top of the cylinder to and through its bottom, and a screwed projection on the bottom for attaching the ubricator to the part to be lubricated. On the top opening of the channel, within the cylinder, is an adjustable sliding piece, which is made to partially close the channel, and so regulate the flow of oil to the part lubricated. This sliding piece has a cup-like aperture, which collects and guides the oil to the channel. Upon the opposite side of the container to that in which is the channel is fixed a piece of bent plate similar in shape to a spoon. The action of the lubricator is due to the reciprocating motion of the part to which it is attached throwing the oil up by the aid of the spoon unto the mouth of the channel. From the channel it trickles down into the part to be lubricated. An advantage of such a lubricator is that it only feeds whilst the part is in motion. Five claims are made.—No. 17624. November 5th, 1889. 8*d.*

Feeding Liquid Fuel to Furnaces.—*G. R. Young, Charlton, Kent.*—An important feature in this invention is the employment of a jet of steam at the top and bottom of the discharge nozzle for drawing the liquid fuel out in a spray into the furnace. Another feature is the provision of appliances for separating from the liquid fuel any impurities and any ammonia or water contained in it. The illustration shows a central vertical section upon the

side elevation of the apparatus. A is a cylindrical or other suitably shaped chamber or receptacle for the tar, oil, or other liquid; B is a pipe communicating with any suitable supply of tar, oil, or other liquid fuel; C is a strainer or filtering chamber placed between the said pipe and the chamber or receptacle A; D is another pipe communicating with any convenient source of steam supply. The steam passes from the pipe D, round the coil J, along pipe K to the chamber U, from the chamber U it passes out through the opening F from between the nozzle and the plate G. The opening in the plate G is oval, whilst the nozzle is round, thus the openings F for the discharge of the steam are of a crescent shape. The discharge of the steam through F induces a flow of liquid fuel through the nozzle, the flow being regulated by the adjustment of the rod Y and valve N in a manner apparent from the drawing. Eleven claims are made.—No. 8118. May 15th, 1889. 8*d.*

Governors.—*A. W. Cooper, Dundee.*—The inventor describes a form of governor preferably adapted to control the action of trip valve motions. Upon the vertical shaft is a collar C, which slides upwards and downwards with the motion of the balls. The collar C slides upon a feather fixed in the shaft, and it is constructed with flanges D and a groove E. In the groove E



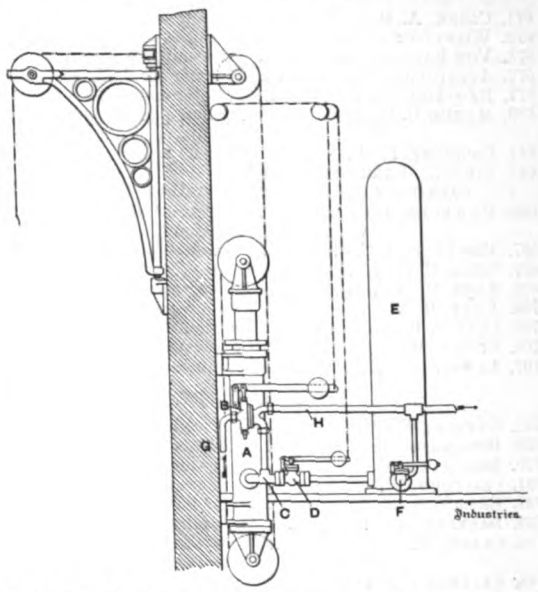


FIG. 2.

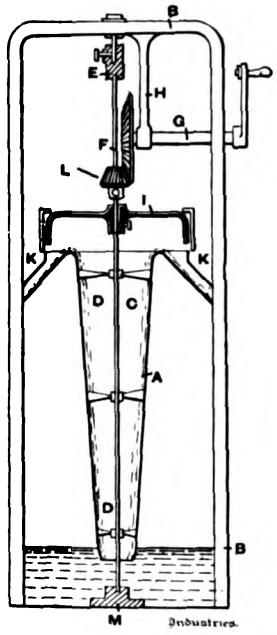
works part of a weighted lever F, and between the flanges D are rollers T. Upon one end of the lever F is a pulley S, whose revolution operates an adjustable joint G^1 which controls the valve motion through the lever K and rod I. Round the pulleys S T Q and tension pulley R passes an endless band. The action of the appliance is as follows:—As the rollers T only just clear the flanges D, any distinctive rise or fall of the latter causes the former to be revolved in one of two ways. The revolution of the rollers T gives motion to the endless band, and thus also to the pulley S. The pulley S revolving, operates the adjustable joint G^1, and so the trip valve motion is controlled. Claims: (1) The improvements for the automatic regulation of steam distribution within steam engines as prime movers; (2) the employment of floating stirrup spanners with discs for transmitting motion; (3) the employment of floating collar, with discs gearing with vertical rods; (4) method of adjustment for floating of disc by springs between brackets and adjusting nut; (5) tension arrangement for lever arrangement.—No. 1360. January 25th, 1889. 8*d.*

Spinning and Doubling Machines.—*J. Dickinson, Manchester.*—The object of this invention is to prevent what is known as "ballooning" on ring frames, especially when spinning or doubling upon bobbins of more than five inches in length. The method of carrying this into effect will be seen from the following claims. Claims: (1) So mounting the guide wire flaps or lappets of ring spinning or doubling frames that they can be brought down below the horizontal position to within a very short distance from the tops of the spools when commencing a fresh set of cops, and then raised up above the horizontal position, either by hand or automatically, as the winding proceeds; (2) refers to a form of guide wire flap, constructed by inserting the guiding wire into one end of a block of wood which is attached at the other end to a short piece of tube. The tube is supported by a rod passing through it, making a hinged like joint for the flap. A pin passes through a slot in the tube into the supporting rod, to keep the flap in place and at the same time permit it to be turned up for piercing up. The rod is attached to a hand lever by which it is turned and the wire guide raised or lowered; (3) refers to a modified form of the invention; and (4) to automatic arrangement for raising and lowering the guide wire.—No. 3321. February 25th, 1889. 8*d.*

Hydraulic Cranes.—*H. C. Walker & R. Carey, London.*—An improvement is here made in the method of bringing back the crane chain when the crane has been used for lowering goods. By the use of an air reservoir the water in the lifting cylinder is used to bring back the chain without any other pressure being expended on it but that caused by the lowering of the load. Referring to the illustration, A is the lifting cylinder and B its controlling valve, with inlet G and exhaust outlet H. The lifting cylinder is also in communication with an air vessel E through the pipe C and its controlling valve D. The valves are shown to be worked by chains. When lowering a load the water in the cylinder A is allowed to escape into the air vessel E by raising the valve D. The water passing into the air vessel E compresses the air contained in it, and stores up energy. When the chain is

to be brought in, the valve D is reopened and the water passes back from the air vessel into the lifting cylinder under the pressure of air previously formed. To bring the chain back to its greatest height, an automatic valve may be arranged to admit water under pressure to the lifting cylinder at the end of the stroke. Claim: In hydraulic cranes, hoists, and the like, the employment of an air vessel or vessels of suitable capacity, together with the necessary valves and pipes, in order that the lifting cylinder may exhaust into or be supplied from this said air vessel or vessels at will.—No. 2282. February 8th, 1889. 8d.

Reading and Punching Jacquard Cards.—*C. A. Town, Nottingham.*—This invention relates to apparatus used in reading and punching cards used in jacquards, lace making, weaving, &c. Improvements are made in the means for attaching and detaching the wale strings to the selector needles of the changing frame or punching machine. The ends of the selector needles are formed to receive detachable end pieces, which are fitted to the needles by a male and female joint and retained by a spring catch. These detachable end pieces are carried in holes formed in an additional box, the holes corresponding to the position of the selector needles. The box slides freely on and is held in position by two pins secured to the back of the needle box, and is provided at the back by a sley with holes of a reduced size for preventing the withdrawal of the detachable end pieces from the box by the wale strings. The wale strings are permanently attached to the detachable pieces of the selector needles, and the two are, together with the box in which the detachable ends are carried, removed to insert lathes by reading in the usual manner for punching a fresh pattern. By this arrangement the process of hooking on is entirely done away with. Six claims are made.—No. 3275. February 23rd, 1889. 8*d.*



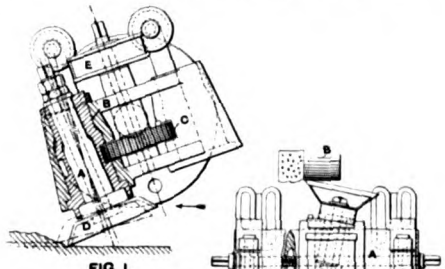
Pistons.—*W. G. Kent & H. S. Price, London.*—The piston is formed with a circular plate fitting the bore of the cylinder. On each side of the disc is a washer of leather, rubber, or other elastic material. These washers are shaped with one or more suitable corrugations around the outer part, so that the washers touch the disc at their centres and edges, but are bulged away from the disc between those parts. A metal plate of the same form in cross-section as the elastic washers is fitted over each of them. Holes are cut in the metal plates in the bulged part.

Digitized by Google

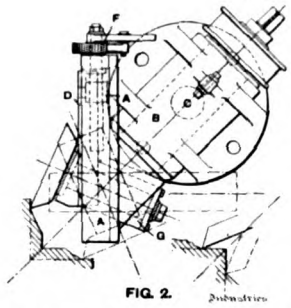
The tendency of the steam in the cylinder when the engine is at work is to enter the holes in the bulged part of the plates and compress the bulged part of the elastic washers, thus causing their periphery to be pressed against the cylinder and make a steam-tight jacket. Five claims are made for the form of piston described.—No. 2772. February 16th, 1889. 8*d.*

GRINDING ROLLS IN TINPLATE MILLS.—*J. H. R. Ritson & W. Jenkins, Neath.*—Hitherto it has been difficult to polish the rolls of tinplate mills without stopping the mill and allowing the rolls to cool. The inventors propose to remedy this by attaching to the mill an appliance which will grind the rolls without allowing them to cool if so desired. Suitable brackets are attached to the framing of the mill upon each side, and support one or more rods and a screwed shaft, which reach across the mill parallel to the rolls. The rods act as guides for a bracket, which carries the block of emery or material for grinding the rolls. The bracket is screwed to receive the screwed shaft, by which it is fed gradually along the faces of the rolls from end to end. The block of emery is shaped to suit the contour of both rollers, and can be adjusted in its supporting bracket to press against them in any position required. In place of the emery block as above described, a pair of emery polishing wheels may be used, and rotated by a strap driven from a drum pulley fixed in the mill-framing above the rolls. The screwed shaft might be substituted by a rack, and the supporting bracket for the polishing block provided with a wheel gearing into the rack. Claims: (1) In machinery or apparatus for polishing or grinding rolls used in tinplate and other machines, the polishing surfaces or blocks mounted and carried by travelling mechanism as and for the purpose described; (2) in machinery and apparatus for polishing grinding rolls used in tinplate and other machines, the arrangement of mechanism described and shown for regulating and operating the polishing surfaces as described.—No. 3551. February 28th, 1889.

CENTRIFUGAL PUMP.—*J. Martinez-Ancira, Paris.*—The pump is constructed of a vertical rotating tube open at both ends, and its diameter increasing from the bottom upwards. The illustration gives a vertical section of the apparatus. D is the tube mounted upon a vertical shaft which is rotated in any suitable manner as shown. By rotating the tube it may be seen that the water will ascend close to the side of the tube. Over the tube is a deflector I, for deflecting the water, as it is delivered from the tube, down into the delivery pipes K. Claims: (1) The improved centrifugal pump as described; (2) in a centrifugal pump



the use of a vertical conical tube which dips into the liquid to be raised, and is carried by a central vertical spindle, to which rotary motion is communicated in any convenient manner; (3) in a centrifugal pump the use of a rotating vertical conical tube, to which is attached internally a spiral; (4) in a centrifugal pump the combination of a vertical conical tube, to which rotary motion is communicated in any convenient manner, with a collector surrounding the upper end of said tube; (5) in a centrifugal pump, in which a rotating vertical conical tube carried by a central spindle is employed, the use of a deflector I, mounted adjustably on the same spindle.—No. 17505. November 4th, 1889. 6*d.*



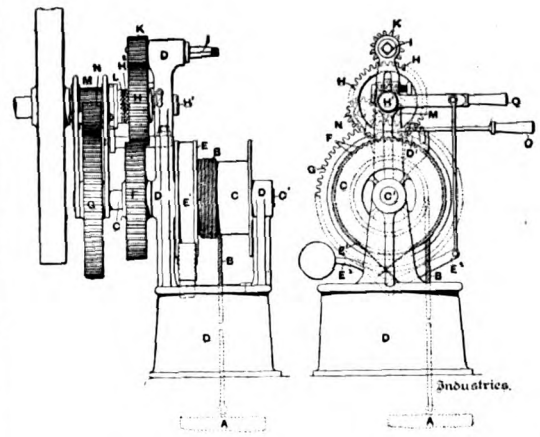
PADDLE-WHEEL BOATS.—*J. S. Baker, New York.*—The novelty of this invention lies in the arrangement of the paddle wheels horizontally—that is to say, with their axes of rotation vertical. The wheels are fixed in recesses in the hull of the vessel below the water line. The blades of the wheels are arranged in planes inclined to the wheels' axes to tend to lift the vessel forward and get more effective pressure from the water. Claims: (1) The combination with a boat of a horizontal paddle-wheel projecting from a recess in each exterior opposite side of the hull below the water line, and located forward of the middle and where the shape of the hull has a parting action on the water, and the wheels have buoyant effect upon the bow; (2) in a boat having horizontal paddle wheels located in and projecting from recesses in the side of the hull below the water line, and located forward of the middle, said wheels constructed with a spiral pitch of the paddles directed so that the reactionary effect of the water has a lifting action on the wheels; and (3), (4), (5), and (6) referring particularly to the method of fastening the blades to the disc or discs of the paddle wheels, and for the construction and arrangement of paddle wheels as described.—No. 11106. July 10th, 1889. 6*d.*

GAS ENGINES.—*M. J. Adams, York.*—The improvement consists of an arrangement by which the pressure obtained by the explosion of gas, petroleum, or other vapour is utilised to drive a motor. The gases are exploded in a chamber and then allowed to pass into and accumulate in a reservoir. From the reservoir they are drawn off as desired to the cylinder of the motor.

Claims: (1) The combination of a reservoir of suitable size with a chamber in which ignition or explosion of gas or vapour shall take place, such reservoir supplying to the working cylinder of an engine the pressure necessary to impart motion thereto; (2) the arrangement and design of parts as shown and figured in the specification of the patent.—No. 3331. February 26th, 1889. 6*d.*

MACHINERY FOR WORKING STONE.—*F. Trier, London.*—Improvements are here described in the tool holders for circular rolling cutters. The objects effected are—1st, the skewing of the cutter to the plane of the stone; 2nd, the cutting in steps by means of one cutter; 3rd, the production of internal and external angles by one cutter. The first of these objects is attained by fitting the spindle A which carries the cutter D within the bush B, such that the axis of the one crosses the axis of the other. The bush B may be turned on its axis by the gear wheel C, and thus give the cutter any desired screw. The second object is effected by turning the bush B halfway round at the end of each stroke, and so shifting the cutter D from the position shown in full lines to that shown by the dotted Fig. 1. An advantage of this arrangement is that a roughing cut is taken as the stone or the cutter travels in one direction, and the finishing cut as the stone or cutter makes the return movement. The semi-rotation of the bush B may be made automatically by the method known as the "Jim Crow" movement. A rope is passed round the pulley E, and connected to the movement. To effect the third object, a slide A, Fig. 2, is mounted upon the trunnion B at an angle of about 45° to the directions in which the trunnion

slides. The trunnion is made to swivel upon its centre C. On the slide A is a second slide D carrying the circular tool-holder G. The slide D is worked backwards and forwards upon A by a screw and ratchet wheel arrangement F, which is itself actuated automatically. When one side of the angle has been cut, the slides and cutter holder are turned into the position shown by the dotted lines by swivelling the trunnion, and the second side is then cut. Fig. 2 also shows the application of the cutter to the work in cutting outer angles. Fig. 3 shows an improved grindstone dresser, the chief improvement being the employment of a tubular slide A. The apparatus is shown at work upon a grindstone B. Claims: (1) The manner of giving skew to a cutter substantially as described; (2) step-cutting with one cutter; (3) the construction of the tool-holder substantially as described and illustrated by Fig. 1; (4) cutting internal and external angles with one cutter substantially as described with reference to Fig. 2; (5) the construction of a grindstone dresser using rolling cutters with a tubular slide and movable feet substantially as illustrated and described with reference to Fig. 3.—No. 355. January 8th, 1889. 8*d.*



ROLLING MILLS.—*H. H. Lake, London.* (*The Proprietors of the Copenhagen Horse-Shoe Manufactory.*)—In this invention a device is described for feeding the blanks of horse-shoes to rollers. A disc of metal is fixed before the rolls with its axis vertical, and in the edge of its upper surface are inserted perpendicularly pins or studs of metal. The blank in a heated state is placed upon the disc, and the disc revolved until the blank has assumed the proper position for passing between the rolls; the blank is then pushed forward by the attendant, and is taken in by the rolls. The vertical pins are for the purpose of keeping the blanks from falling off the disc. Claim: A feeding device for rolling mills for rolling small articles, consisting of a disc, a fixed or rotary standard for the same to revolve upon, and a stand for supporting the whole as described.—No. 1185. January 22nd, 1889. 6*d.*

JOURNAL BOXES.—*J. F. Morell, Camden, New Jersey, U.S.A.*—The journal is constituted by a number of anti-friction rolls and rings, having concave and convex surfaces to keep them in proper position, and permit, in the case of car wheels, the car to oscillate without injury to the bearings. The main shaft is turned with its surface raised and convex. The convex surface of the shaft works in the exterior and concave surfaces of two annular rings. The inner surface of each annular ring is flat and works against a number of small rollers kept in position by a second annular ring concentric to the first. The rollers are also in contact with a supporting stud or axle upon which the whole are supported. The axles of the small rollers work in slots in the second annular ring, thus being kept at their proper distances from each other. When the shaft is in motion, the first annular rings rotate in contact with the shaft and the small rollers, and the rollers are caused to revolve upon the surface of the supporting stud. Claims: (1) A journal of the form of a frustum, of a circular spindle, and a roller or bearing for the same, having a concave periphery to receive said journal combined and operating as described; (2) a hollow friction roller for a journal or axle, containing a circle of friction rollers and having a concave periphery in combination with a journal of the form of a frustum, of a circular spindle occupying said concave periphery, as described; (3) the combination of the journal with the hollow rollers, the axles within said hollow rollers, and anti-friction rollers within the said hollow rollers and bearing on the inner face of said rollers and on the axles, as set forth; (4) a hollow friction roller for a journal or axle, containing friction rollers and slotted rings for supporting the said rollers as described.—No. 18504. November 19th, 1889. 6*d.*

LOOMS.—*L. H. Marsden & J. H. Frost, Manchester.*—The improvements refer to the slackening motion for slackening the dupe thread in weaving leno work. Upon the top rail of the loom are fixed brackets to support a shaft parallel with the top rail. To this shaft are attached two or more levers, the ends of the levers being flattened surfaces, which are arcs of a circle described from the centre of the shaft or thereabouts. These levers are made in two parts, so that their radii are adjustable. To the curved surface of these levers are attached cords, which support a horizontal rod whose ends slide in guides. This rod carries the dupe or leno thread as it comes from the yarn or warp beam. The rod is lowered for the purpose of slackening the thread by dropping the curved ends of the levers. To drop or raise the levers another lever or finger is attached to the shaft and projects from it in a contrary direction to the curved levers. To the end of this finger is attached a spring for depressing it and a cord for raising it. The cord for raising it is attached to the tappit, dobbie, or jacquard, which causes the lever to be raised or lowered at the proper time, and so the thread to be slackened, &c. Claim: The arrangement of parts as described—either with adjustable or non-adjustable curved ended levers—for lowering the rod over which the leno thread passes from the yarn or warp beam, to give the slackening required for the twist of the thread.—No. 18733. November 22nd, 1889. 6*d.*

STARTING ENGINES.—*B. Smith, Bath.*—An appliance is here described for attaching to engines operated by gas or oil for giving them the impetus necessary to set them working. The appliance is constructed to accumulate energy when the engine is stopped, and expend it in revolving the crank shaft when the engine is required to be started. Fig. 1 is a side elevation of the apparatus attached to the crank shaft, and Fig. 2 a front elevation. Upon a shaft C^1 are keyed a double drum and two spur wheels F G. The smaller part of the drum C received a rope B by which a weight A is suspended, whilst the larger part of the drum E constitutes with the band E^1 a friction brake. The spur wheel F is in train with two other wheels H and K. The wheel is fixed to a spindle which revolves in a bearing in the frame and

FIG. 1. FIG. 2.

terminates in square shank I. The wheel H is free to revolve upon a shaft H^1, and has upon one side a serrated boss H^2 which constitutes with a similar face L a clutch. The spur wheel G is in train with the wheels N M. By the lever O the wheel M^1 may be put in and out of gear with the wheel N, and by the lever Q the friction brake and clutch are operated. When the appliance is being wound up the wheel M is put in gear, and the weight is raised, as may be seen from the drawings. To start the engine the wheel M is taken out of gear, the clutch put into contact, and the brake released, permitting the weight to descend and revolve the engine shaft. When the engine has reached its working speed or the weight has fallen to the bottom the clutch is disconnected and the brake applied. The square shank I permits the appliance to be wound up by a hand crank. Seven claims are made.—No. 2762. February 16th, 1889. 8*d.*

REVERSIBLE ROPE DRIVING GEAR.—*R. Hornsteiner, Prague.*—The inventor describes a method of driving and reversing the motion of shafts, by gut, rope, or such like bands. A V-shaped grooved pulley is fixed upon the shaft to be driven, between two other loose pulleys, which are grooved by a circular-shaped groove. An endless band passes round one of the loose pulleys, and round two guide pulleys, back again to the fixed pulley upon the shaft. The endless band always runs in the same direction, and its motion upon the fixed pulley is contrary in direction to that upon the loose pulley. From this it may be seen that if the turn upon the fixed pulley is shifted to the other and unengaged loose pulley at the same time the turn upon the loose pulley is shifted to the fixed, the motion of the fixed pulley is reversed. One of the guide pulleys may be the driving pulley. The bands are shifted by two forks fixed to slides in the usual manner, but operated simultaneously by pins upon each slide working in grooves in a third sliding plate. The fixed pulley may be made with two V-shaped grooves, one with less diameter than the other, to make the motion more rapid in one direction. The loose pulleys then would have to be of corresponding diameter to the diameters of the grooves. In the case of a single grooved fixed pulley, the loose pulleys may be double grooved, to permit the fixed pulley to be thrown altogether out of gear. In this case the turns of the band would be upon alternate grooves. Claims: (1) The driving and reversing gear described in combination with the transmission or guipe pulleys described; (2) in the construction of driving gear as aforesaid, the combination of two pairs of

Digitized by Google

pulleys of different diameters as described, the two fixed ones being attached to each other or separate; (3) in the construction of driving gear as aforesaid, the combination of three pulleys of equal diameter, the inner and fixed pulley single grooved, the outer and loose pulleys single or double grooved, for the purpose and in the manner described; (4) in the construction of driving gear as aforesaid, the combination and arrangement of two loose pulleys, so fitted as to be alternately coupled to the shaft; (5) the general constructions, combinations, and arrangements of parts together constituting the improved reversible driving gear. —No. 18116. November 13th, 1889. 6*d*.

GAS PRODUCERS FOR MARINE STEAM BOILERS.—*G. Scott, Glasgow.*—The gas producers are placed before each furnace of the marine boiler to supply it with combustible gas. The usual fittings of the furnace are removed, and, in place, a number of narrow channels are built with refractory material one above the other in the bottom of each furnace. These channels communicate at the back of the boiler with the atmosphere, air being permitted to enter and pass up in a zigzag manner to the upper half of the furnace just under the entrances for the gas. The channels for the admittance of air become heated by the combustion of the gases in the upper half of the furnace, and so the air becomes heated by passing through them. The furnace is entirely closed, except for the entrances mentioned, and adjustable openings in the front to regulate the supply of cold air to the furnace. The action is as follows:—Gas is produced in the gas producer and admitted as desired to the furnace, in which it meets with a supply of hot and cold air and is consumed, the products of combustion being conducted through the boiler in the usual manner. Claims: (1) In the generation of steam in marine steam boilers, the employment of gas producers for the purpose of supplying the boiler furnace or furnaces with gas for combustion; (2) in the generation of steam in marine steam boilers, the general arrangement and construction of the various parts constituting the improvements as described.—No. 18714. November 22nd, 1889. 6*d*.

MACHINE FOR DRAINING LAND.—*J. H. Rimell, Chipping Campden, & F. Clements, Weston-sub-Edge, Gloucestershire.*—The machine is designed for making channels below the surface of the land to convey away the water to the various dykes, &c. The tools proper are mounted upon a frame similar to that of a plough, and are worked either by horse or steam power. In the illustrations Fig. 1 is an elevation, and Fig. 2 a plan of the machine. The first tool B upon the frame A is for the purpose of cutting and turning aside the turf. The second tool C is a sharp cutting blade, which penetrates sufficiently deep into the ground to make

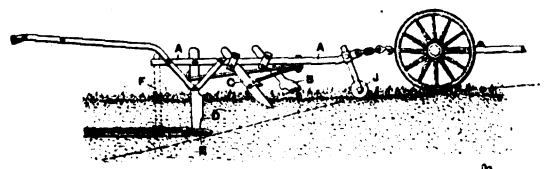


FIG. 1.

FIG. 2.

a vertical slit to ease the work upon the last tool D. The tool D terminates in a bullet-shaped head E which forms the channel. Behind the tool D may be placed a fourth for sleeking the channel and removing any obstacles that remain in the channel. The depth of the channel is determined by adjusting the wheels F and J, and the wheel F is placed in the position shown by the dotted lines for removing the appliance on roads, &c. Claim: An improved machine for draining land by horse or steam power substantially as and for the purpose herein set forth and shown upon the drawings.—No. 18144. December 12th, 1888. 8*d*.

APPARATUS FOR COOLING CLOTH.—*A. Armitage & T. Carter, Huddersfield.*—The cloth which has become heated by the process of tentering is cooled by passing cold air through it by an apparatus of the following description: The cloth as it leaves the tentering machine is passed over a roller through a flat rectangular box. In opposite sides of this box are pierced holes in a direction perpendicular to the surface of the cloth. These holes are in communication with an air fan, which blows air into the rectangular box through the holes, and out by slits in the ends of the box where the cloth enters and leaves the box. Claims: (1) For the purpose of cooling cloth which has become heated during the tentering process, the employment of a rotary fan blowing cold air into a cooling box through which the cloth passes, the cooling box being provided with air passages and slits opening upon the cloth being cooled, all the various parts being constructed and operated in the manner described; (2) an apparatus for cooling cloth after it has passed the tentering machine, the general arrangement and combination of the rotary fan with the air passages and slits in the cooling box, and a regulating tongue, for distributing the air over the cloth.—No. 3194. February 22nd, 1889. 6*d*.

IRON AND STEEL FURNACES.—*L. Roberts & J. Jones, Stockton-on-Tees.*—The inventors here describe an apparatus for introducing pig and scrap iron into a steel or iron furnace, the object being to obtain a more uniform and methodical feeding than is possible by hand. A charging peel is slung from a travelling frame which runs on overhead pulleys and which is supported on a rail. The rail is of such a length and is arranged in such a manner that the peel can easily pass through the feeding hole and be withdrawn to a sufficient distance for receiving its charge. The peel is in the form of a shaft which has a shovel at one end and a two-pronged handle at the other. On insertion in the furnace the handle is turned and the charge of pig or scrap iron is overturned. In order that the charging peel may be supported inside the furnace within a short distance of the shovel the travelling frame is constructed to follow it into the furnace. The frame is made of two horizontal bars which extend from a common vertical bar. The upper arm of this frame is secured to the overhead pulleys which run upon the rail, and the charging peel is slung upon the end of the lower arm. Claims: (1) In combination with open-hearth furnaces the construction and use of apparatus or combinatfon of mechanical appliances in which a charging peel is slung from the arm of a travelling frame by which means it is inserted into and withdrawn from and otherwise manipulated for charging the furnaces; (2) the use of bogies constructed with troughs or channels formed between ridges upon which the pig iron or scrap metal is lodged to enable the peel to be inserted underneath.—No. 2369. February 11th, 1889. 8*d*.

ELECTRICITY.

ELECTRIC SWITCHES.—*S. Z. de Ferranti, London.*—The switch is designed of small dimensions, yet capable of passing currents of very high tension to or from either one or other of two pairs of conductors from or to a third pair. Fig. 1 is a side elevation of the switch, Fig. 2 an end elevation, Fig. 3 a plan, and Fig. 4 a diagram showing clearly the working of the switch. A B are two short lengths of conductor carried at a distance apart from one another by a slide C, which can be slidden to and fro along two fixed parallel rods D. E F^1 F^2 E^3 are metallic brushes with which the upper ends of the conductors A B can be brought into contact. The brushes E E^1 are coupled with one another by a conductor I, and the brushes E^2 E^3 by another conductor J. The conductors I J have coupled to them two conductors Z Y of an electrical circuit, say from a dynamo electrical machine. F F^1, G G^1 are four metallic brushes with which the lower ends of the

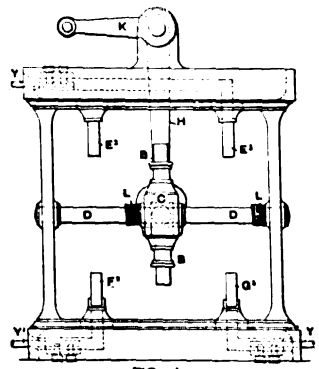

FIG. 1.

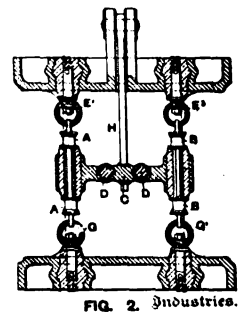

FIG. 2. Industries.

conductors A B can be brought into contact. The brushes F F^1 have conductors X^1 Y^1 leading from them, and the brushes G G^1 have leading from them other conductors X^2 Y^2. When the conductors A B are brought into contact at the top with the brushes E E^2, and at the bottom with the brushes F F^1, the conductors X^1 Y^1 will form continuations of the conductors Z Y, but when the conductors A B are at the top in contact with the brushes F^1 E^2, and at the bottom in contact with the brushes G G^1, the conductors X^2 Y^2 will form continuations of the conductors Z Y. In this way whenever the slide C is moved so as to carry the conductors A B away from the brushes E E^2, F F^1 or E^1 E^3, G G^1, the circuit will be broken at four points. The slide C is shown as being moved along the guide rods D by a lever arm H turning on a pin. The lever can be

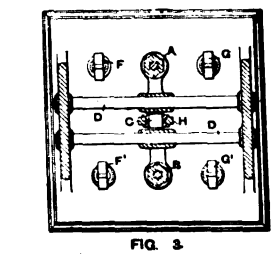

FIG. 3.

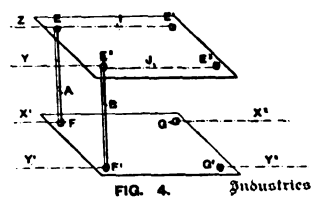

FIG. 4. Industries

rocked by a second arm K upon it, to which movement may be given in any suitable way. L L are spring stops or buffers for the slide C to strike against at one or other end of its movement. Claims: (1) A switch for putting one pair of conductors into connection with either one or other of two other pairs of conductors in which whenever one or other of the circuits is broken it is broken simultaneously at four different points; (2) the arrangement of the coupled contact brushes E E^1 and F^2 E^3, the brushes F F^1, G G^1, and the conductors A B, which can be shifted either into a position to put the brushes E E^2 into connection with the brushes F F^1 or with the brushes G G^1; (3) the construction of electrical switches as described.—No. 915. January 17th, 1889. 8*d*.

PRINTING TELEGRAPHS.—*J. E. Wright & J. Moore, London.*—In the ordinary forms of column printing telegraphs the type wheel shafts are such that a good deal of friction is caused as the type wheel slides along it. The inventors, therefore, make the shaft with two or more knife edges, so that not only is the friction reduced, but the shaft is made lighter. A knife-edge bar is also used for the propelling mechanism of the type wheel to slide upon. It is also stated that these knife edges also prevent the usual shake of the type wheel. Claims; (1) The construction of the type wheel shafts of column printing telegraphs with two or more longitudinal V or knife edge projections or grooves for corresponding grooves or projections on the type wheel to bear upon to reduce friction and peripheral shake during the operation of printing; (2) the combination of the type wheel shaft having longitudinal V or knife edge projections or grooves, the type wheel with corresponding grooves or projections, the carriage sliding upon a bar similarly formed with projections or grooves, and the arm from the carriage entering a groove cut around the circumference of the type wheel.—No. 2413. February 11th, 1889. 6*d*.

INCANDESCENT ELECTRIC LIGHTING.—*J. Hartness, East Boldon, Durham.*—The inventor's object is to localise the electric light by attaching it to some convenient part of the body of man or beast, thereby securing portability, and bringing the light as near the work in hand as may be desired. The lamp may be secured to the cap or headgear of the operative requiring its light, a peak intervening of sufficient length to shade the eyes. The lamp is attached by a swivel or knuckle joint, and connecting to the main leads of an electric generator by branch wires, which are slack to allow the operator to have free movement. The lamp is designed for the use of operatives having such work to perform as the examination of chains, anchors, and fine work. Claim: The combination with the dress head-gear or person of the user of an electric lamp or lamps supplied with current from an electric generator.—No. 3330. February 25th, 1889. 6*d*.

CABLES FOR ELECTRIC CONDUCTORS.—*S. Pitt, Sutton, Surrey (A. Dey, New Brunswick, New Jersey, U.S.A.).*—The improvements in this invention are described in the following claims: (1) An electric cable, comprising a conductor or multiple conductors, each covered with a spiral wrapping of paper ribbon, and the whole being enclosed in an impervious sheath, such for instance as lead; (2) an electric cable, comprising multiple conductors, each wrapped spirally with insulating ribbons of manilla paper, the conductors being twisted in pairs, and all the twisted pairs then twisted together, and an impervious sheath, such for instance as lead, closely enveloping all the conductors. —No, 18,748. November 22nd, 1889. 6*d*.

CHEMISTRY.

MANUFACTURE OF CHLORINE.—*T. Parker & A. E. Robinson, Wolverhampton.*—The inventors here describe a new process for the manufacture of chlorine by electrolysis. The electrolysing vessel is divided by means of a porous diaphragm, and the two adjacent spaces are filled with solutions of common salt and a metallic sulphate respectively. The most convenient sulphate for ordinary use is that of iron, though copper or zinc sulphates may be used if there is any particular advantage in so doing. On a current of electricity being sent through the bath the sulphate and chloride are decomposed, the iron and chlorine are liberated in the separate compartments, and the sulphuric acid combines with the sodium to form sulphate of soda. The chlorine and the sulphate of soda are abstracted in any suitable manner. The inventors claim (1) the production of chlorine by the simultaneous electrolysis of common salt and a metallic surface in the vessel described; and (2) the vessel composed of two compartments separated by a porous diaphragm for the purpose described.—No. 2310. February 9th, 1889. 4*d*.

CYANOGEN COMPOUNDS.—*T. Parker & A. E. Robinson. Wolverhampton.*—The inventors here describe an electrolytic method of producing cyanides from sulphocyanides. The sulphocyanide is first treated so as to give up free sulphocyanic acid, and the liberated acid is split up into sulphuric and hydrocyanic acids by the action of a current of electricity. The hydrocyanic acid is condensed either in water to form the acid of commerce, or in an alkali to form a cyanide. The inventors also describe a commercial method of producing these chemicals from gas liquor. Two claims are made.—No. 2383. February 11th, 1889. 4*d*.

ARTIFICIAL SILK.—*J. H. du Virier, Paris.*—The inventor describes a method of making artificial silk filaments from pyroxyline. After the cotton has been trinitrated it is dissolved in glacial acetic acid, and is mixed with a solution of gutta percha in bisulphide of carbon and with a solution of isinglass in glacial acetic acid. After this mixture has been kneaded together with a small proportion of castor oil and glycerine, it is ejected under pressure through small orifices into a reservoir of water. The filaments thus formed are led through a series of baths, for the purpose of cleansing and strengthening them, and they are afterwards reeled in the usual way pursued with silk fibres. There are five claims.—No. 2,570. February 13th, 1889. 8*d*.

MISCELLANEOUS.

SPINDLE BEARINGS.—*B. R. Bond, London.*—This invention relates to apparatus described in Patents No. 5605 of 1888 and No. 14868 of 1888, for measuring and otherwise manipulating cloth; and the present invention relates to improved methods of mounting the spindles upon which the cloth is intended to be wound. The axle consists of a bar of metal, or other suitable material. The ends of the axle are supported by revolving plates, which work in bearings formed in stationary plates fixed to the framing of the apparatus. The revolving plates may be made in two parts and bolted together, so as to revolve in a circular opening in the stationary plate, or the revolving plate may be a single plate, revolving in a groove formed in the stationary plate. There are four claims.—No. 19001. December 29th, 1888. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

WIRE COVERING MACHINE.

THE machine which we illustrate in Fig. 1, and in front elevation and part section in Fig. 2, and partial transverse sectional view in Fig. 3, is expressly designed to effect the covering of wire for electrical purposes.

A machine of this class is usually constructed with several heads or sections, each of which is independent to a large extent of the rest. One of these will be described. On the driving shaft J, which extends along the machine, a number of discs M are keyed, there being one to each head. Adjoining each disc, and to a certain extent covering it, is a grooved disc or pulley N. One side of this disc is hollowed and has a circular leather plate fixed in it, which acts as a frictional surface by which N is driven when pressed up to M. Over the pulley an endless band K is passed, the course of which is shown by the dotted lines in Fig. 3, and which drives the two rotating spinning heads B and C in opposite directions. The grooved disc can be slid upon the shaft by means of the lever F, by moving which to the left contact of the frictional surfaces is established or *vice versa*. The wire is drawn from the reels A—shown in place at the upper part of the machine in Fig. 1—and is passed through the hollow spindles of the spinning head, after which it follows the course shown until it reaches the draw roller E, on which it is taken a complete turn. The rate of rotation of the draw roller regulates the speed of covering, and the reels G, upon which the covered wire is wrapped, are driven by a band from the shaft on which the draw roller is fixed, so that the speeds of the two are relatively proportionate. The covering material is carried in spools fixed upon pins fastened in the face of the spinning discs L. Instead of driving the shaft O and draw roller by bevel gearing, they are driven by a worm and worm wheel, the former being fixed on the driving shaft. In this way a regular speed of traverse is obtained, entirely free from the irregularities arising from back lash when ordinary gear wheels are used. This is important for the reasons previously given. The stop motion consists of a small finger U, attached to the spinning disc in such a way that as the latter is rotated the finger tends to assume a perpendicular position. It carries an eye, through which the yarn is passed, the tension upon the latter being sufficient to prevent the finger from taking the position named. As soon as the end falls the finger assumes the perpendicular, and in its rotation strikes one end of the small lever V, which is oscillated through an arc of 90 deg. The movement communicated to V causes the part X to descend and press a small weight D, which is suspended by a cord in a slot of the lever B. On the latter is a projection, in front of which the weight is forced, and is thus brought into the path of a cam on the driving shaft. In this way the lever is pressed back, and by means of the connecting rod S^1 it raises and releases the lever F^1, so that it can be drawn over by a spring, and the section is thus stopped in the manner previously described. To restart the machine it is necessary to piece up the thread and restore the small lever V X to its original position. This is done by a small lifting rod Z, specially provided and arranged to act for both discs.

The machine we have described has been found to possess many advantages, and an important works in the neighbourhood of Manchester has been fitted with it. It is capable of a larger turn-out than other machines, owing to the regularity of its working and the rapid stoppage of the heads, which obviates winding back and facilitates piecing. The covering can be guaranteed to be satisfactory, and the cost of labour is reduced by each head being worked automatically. The makers are Messrs. Thomas Barraclough & Co., Limited, of Manchester.

NOTES ON PATENTS.

II.

COMPULSORY LICENCES.

IF a patentee refuses to grant licences on reasonable terms, the Board of Trade may compel him to do so in either of the following events:—(*a*) That the patent is not being worked in the United Kingdom; or (*b*) that the reasonable requirements of the public with respect to the invention cannot be supplied; or (*c*) that any person is prevented from working or using, to the best advantage, an invention of which he is possessed. The above is the effect of the 22nd Section of the Patents Act, 1883. The object of this section seems threefold:—To foster English labour and industry; to compel owners of patents to supply public demand; and to enable a person who is the owner of an improvement patent to utilise his invention.

There are, in many European countries, provisions as to the working of patents in the particular country; and in some countries the importation of the articles manufactured abroad according to the patent destroys the validity of the domestic patent. The effect of this has, however, been considerably restricted by the International Convention, which the following (amongst other) countries have joined—viz., France, Spain, Portugal, Italy, Belgium, and Great Britain. Article V. provides as follows:—"The introduction by the patentee into the country where the patent has been granted of objects manufactured in any of the States of the Union shall not entail forfeiture. Nevertheless, the patentee shall remain bound to work (*exploiter*) his patent in conformity with the laws of the country into which he introduces the patented objects (*où il introduit les objets brevetés*)."

It has been said that the provision which practically forces a manufacture in England is a return to Protection. The slightest consideration shows this to be incorrect. Protection means favouring manufactures at the expense of consumers. A compulsory licence would benefit consumers, and certainly not injure them. It is the duty of a State, in granting an inventor a monopoly, to see that the monopoly is not abused, and to grant it subject to such reasonable restrictions that the community at large are not unduly injured. If a patentee does not manufacture in Great Britain he should be compelled to grant licences to manufacture here on reasonable terms. There can be no doubt that the absence of such a provision works great injury to an industry. Take, for instance, the aniline colour trade, the foundation of which was laid by our countryman, Mr. Perkins. At the early stages of the manufacture the industry, for the great part, was in England. Subsequent discoveries in Germany, founded on Perkins' inventions, took away to a great extent the industry from England. The German manufacturers, by patenting in England, completely prevented competition. This is the direct result; but the evil does not rest there. The effect is felt in the next generation, as the manufacture, being in German hands, prevents English chemists from learning their business. The absence of a law to compel working of the patents in England may be said to be one of the main reasons why the greater

Digitized by Google

part of the colour industry of the world is in Germany instead of in England. There are important colour manufactories near Manchester and Huddersfield; but they are small when compared with the combined forces of the Badische Anilin und Soda Fabrik of Ludwigshafen, the chemical industry of Basle, Actien Gesellschaft für Anilin Fabrikation of Berlin, and Farbenfabriken vorm. F. Bayer & Co. of Elberfeld, Messrs. Casella & Co., and Meister, Lucius & Brüning.

Up to the present time there have been no compulsory licences by the Board of Trade. This does not prove that the section is without value, as it acts as a lever to patentees to grant licences on reasonable terms, or to start works in England. The works in England must of course be genuine works, and not merely a depôt into which goods manufactured abroad are received. Reference was made in a recent issue to the important decision under the Merchandise Marks Act, 1887, which would seem to completely protect the English manufacturer against any such fraud. It was held that a manufacturer incurred the penalties of the Merchandise Marks Act by selling as his own manufacture goods purchased from abroad, and that the label "made in Germany" ought to have been placed on the cylinders into which they were eventually placed. The following may be cited as an instance of the second event in which the powers of the Board of Trade can be called into play. It not infrequently happens that a manufacturer buys up a patent to prevent a rival from working it. In such a case the public do not get the benefit of the invention, which is locked up and useless for fourteen years. The third event in which the Board of Trade can grant compulsory licences seems a very just one. An inventor may make an important improvement on, say, the telephone, and may be unable to put his invention into use so long as the master patent exists. The Board of Trade would probably only exercise its jurisdiction in case of an important improvement, and then only on such terms as are just. A provision such as this seems desirable as it promotes invention. Previously the inventor of an improvement, however important, had only one market for his invention, namely, the owner of the patent on which his was an improvement. The two patentees will now be able to treat on more equal terms.

A consideration of these remarks will show that the compulsory licence clauses of the Patent Act are likely to benefit, not merely the manufacturer and the labour market, but also the public and subsequent inventors. The rights of patentees are abridged, but we think patentees may rest assured that their interests will be fully protected by the Board of Trade, whenever their jurisdiction is invoked; and that fair and equitable terms and conditions will be inserted in any licences that may be granted.

THE INSTITUTION OF MECHANICAL ENGINEERS.

On Thursday evening, the 30th ult., the discussion on Mr. Urquhart's paper, "On the Compounding of Locomotives Burning Petroleum Refuse in Russia," was resumed.

Mr. J. Head, who spoke on the previous evening, said that he tried, many years ago, the piston arrangement for the relief of the valve shown in the drawings illustrating the paper read. It worked well for a time, but it soon failed by giving way at the connecting link.

Mr. J. A. F. Aspinall said that Mr. Urquhart was working under favourable conditions in compounding his engines, because where liquid fuel was burned we could have a large blast-pipe, and get rid of the back pressure in the low-pressure cylinder. Another advantage lay in the fact that his engines had outside cylinders. In the narrow space allowed by inside cylinders it was difficult to properly dispose the parts of a compound, so that one could not, so readily as he had done, take old locomotives from the lines in this country and compound them. He, the speaker, had made some trials with liquid fuel, using gas-works tar for the purpose. The results were very satisfactory in all respects except cost. In this country, where relatively coal was cheap and liquid fuel dear, he did not think that the latter could be advantageously adopted.

Mr. Le Page thought that Mr. Urquhart had done wisely in giving greater capacity to the receiver. A further increase would probably be attended with good results. As for compounding with inside cylinders, the difficulty mentioned by Mr. Aspinall was not great. He himself was then engaged on a design in which one set of valve gear was adapted to the two cylinders. He did not see why high pressures should be considered necessary for the efficient working of a compound engine.

Mr. Walker could not understand why there should be so much difference of opinion among engineers as to the advantages of compounding. It seemed to him that the question was to be settled by reference to the coal bills. If Mr. Urquhart found that compounding saved him from 18 to 20 per cent. of fuel, he wanted no further evidence of the merits of the system. As for his own opinion, he had long ago convinced himself of the advantages of compounding, and he recommended that engineers should not allow themselves to be cramped by existing forms and modes of construction, such as inside and outside cylinders, for example; but that they should boldly launch out into something new and more favourable to the conditions involved in expanding in two cylinders.

Capt. Fairholm informed the meeting concerning trials of compounded locomotives made in Germany since 1885, the results of which were similar to those arrived at by Mr. Urquhart, the saving in fuel being from 18 to 20 per cent. In response to a suggestion from the President, he promised to endeavour to obtain, for publication in the Transactions of the Institution, drawings of a new form of valve gear of extraordinary simplicity, designed by Herr Klein, of Chemnitz.

Mr. Young said that the receiver should have a capacity not less than three times that of the high-pressure cylinder. Mr. Urquhart might, therefore, continue with advantage for some time longer on the lines on which he was now moving. He thought, however, that the proper way to equalise the power of the cylinders was to regulate the cut-off with the low-pressure valve.

The President, in closing the discussion, said that, in considering the relative merits of the single cylinder and the compound systems, the conditions under which the engines worked must be taken account of. For marine engines, and for all engines the work of which was regular, the compound was beyond doubt the better system. But for locomotives the advantages were not so clearly apparent. The work of a locomotive was of the most irregular character. In the run from Paddington to Swindon, for example, fully 50 per cent. of the way was downhill. As for the saving in fuel, it was difficult to see how it could be greater than about 15 per cent. at the best. The wear and tear in the compound must certainly be greater than in the non-compound. Possibly not much greater; but it was vain to look for less. There was a source of error in estimating the saving of fuel that more or less vitiated the conclusions drawn from observed facts. He would explain what he meant by quoting instances. Two men were set to drive in turn the same engine over the same line, and in the same circumstances. One always burned 32lb. of coal per mile, the other never exceeded 26lb. In 1847 he, with others, selected eight drivers, and to each of these in turn the locomotive was entrusted for three days, twice repeated. The difference between one man and another in fuel consumption was as great as 22 per cent. Now, in Mr. Urquhart's trials, if the compound was not run by the same man who drove the non-compound engine, we did not know to what the saving was attributable.

The next paper was read by Mr. Michael Stephens, on

The Burning of Colonial Coal in the Locomotives of the Cape Government Railways.

The discovery of the South African coal fields dates back only about sixteen years, when the line known as the Eastern system of the Cape Government was in course of construction. To ascertain the possibility of working this line with Colonial coal known to exist in an outcrop in the Stormberg Mountains, at the spot where the village of Molteno now stands, a mining engineer was engaged to survey the country. His survey was interrupted by the outbreak of the Kaffir war in 1877; but fresh discoveries made within the last few years have added much to the information which he gave in a report issued in 1878. From this it appears that the quantity of coal which can be made accessible by a branch railway from the Eastern system will suffice for the requirements of the existing Colonial railways at the present rate of consumption for about three hundred years. Moreover, outcrops occur in various places, indicating an extension of the coal field far beyond the limits of the recent surveys. Mr. W. Galloway, of Cardiff, in a report to the Cape Government in 1889, says:—"The coal field of South Africa covers a fairly symmetrical area, embracing parts of the Cape Colony, the Orange Free State, Transvaal, Natal, and the whole of Basutoland. . . . . The greatest length and breadth of the coal field within this boundary line are 500 and 200 miles respectively, and its area is about 56,000 square miles. . . . . Up to the present, its fringe has just been touched in a few isolated and far-distant points. It is certain that further systematic researches will be rewarded by the discovery of great stores of mineral fuel, capable of supplying the wants of South Africa for many generations."

The Eastern Railway system, some 300 miles in length, is at present supplied with coal from the two Stormberg mines known respectively as the "Molteno" and the "Cyphergate." The latter, being in direct communication with the railway, furnishes the greater quantity. The cost is 14s. a ton at the mine. The Cyphergate coal is bituminous and gaseous, gives out great heat, and generates steam rapidly as long as the grate is fairly clean; but it contains about 29 per cent. of incombustible matter, which becomes partially fused and forms a pasty mass underneath the incandescent coal, and thus checks the generation of steam by preventing the admission of air between the fire-bars. Attempts were made to overcome the difficulty by means of tipping grates, rocking bars, and other contrivances; but these were not successful, and hand labour was resorted to. The firemen were selected for strength and powers of endurance; the fire-bars were spaced 3in. apart—that is, with 3in. clear open space between them, and the spaces were kept clear by pushing the semi-fused dross through them with the pricker. Owing to the gauge of the railway being 3ft. 6in., the narrowness of the fire-box rendered the grate area sufficiently accessible for the purpose through a fire-hole of the ordinary size. The dross fell between the rails through openings in the ashpan. Occasional halts had to be made for removing through the fire-hole masses of dross which had become set; but apart from such delays the traffic was efficiently worked on a line abounding in gradients of 1 in 40 and five-chain curves. The work of the firemen, however, was exceptionally severe, being closely akin in that respect to puddling; and even the prospect of speedy promotion could hardly induce them to stop at it.

The difficulty has been overcome by the introduction of the movable-bar grate, which is the invention of Mr. J. D. Tilney, locomotive superintendent of the Eastern system of the Cape Government Railways. The fire-bars, which are of cast iron, and spaced 1½in. apart, rest on racks placed near their ends, and have serrated tops. The alternate bars are 1½in. shorter than the others, and have each a lug projecting downwards. A long pin goes through the lugs, and through the ends of two rods which pass from the pin through slots in the damper to the front axle, on which is fixed a drum. The rods are connected to crank-pins in another drum, which the engine-driver can bring into contact with the drum on the axle by means of a hand lever, as in the chain-brake arrangement. A longitudinal motion of 1½in. is thereby imparted through the rods to half the fire-bars; and the dross which has settled on the serrations, being cooled by the air from below, is broken up when the bars are put in motion, and falls through doors in the ashpan, which can be opened and closed from the foot-plate. The dross when set is friable, and not hard like ordinary clinker; and the grate is kept clean by putting the bars in motion occasionally for about ten seconds at a time. Fire cleaning during a journey is thus dispensed with, and the firing of the engines by men of ordinary powers of endurance is rendered practicable. The mechanism is simple and durable; and its introduction has rendered practicable the efficient working of the traffic on an exceptionally heavy line, with the inferior coal, containing 29 per cent. of dross, which crops out on the western boundary of the Cape coalfield.

In the discussion which followed, Mr. Galloway pointed out on the map of South Africa the ascertained boundary of the coal field described in part in Mr. Stephens' paper, and indicated the point down to which the Colonial coal could successfully compete with imported Welsh coal. He stated that no attempts had yet been made to wash the coal, large coal being at present used exclusively. He believed that hitherto no trials of the coking quality of the Colonial coal had ever been made. He had tested the coal practically for locomotive use, and found it to be excellent for the purpose. He could testify from actual experience to the efficiency of the movable-bar grate described in the paper just read.

Mr. White doubted the durability of the fire-bars. As shown in the drawings exhibited, the serrations appeared to him to be too fine. A hard clinker would be likely to throw the mechanism out of gear. In reply to a question, he said that the Colonial coal was used under marine boilers, many coasting vessels and tugs being supplied with the produce of the Indwe mines.

Mr. Woodall said that Natal coal did not contain more than 12 per cent. of ash. It was good for gas making.

The last paper which was read was by Mr. Kenneth S. Murray, on

The Mechanical Appliances Employed in the Manufacture and Storage of Oxygen.

About thirty years ago Boussingault discovered that at a temperature of 1000° F. barium oxide took up another atom of oxygen to form a peroxide, and that when this peroxide was raised to a temperature of 1700° F., this oxygen was given off again free. He recognised the fact that here was a method of obtaining pure oxygen from the atmosphere, but unfortunately the practical success of the operation was rendered impossible by the fact that after a short time the barium oxide lost the power of absorbing the oxygen. This difficulty was never sur-

Digitized by Google

mounted until the brothers Brin, a few years ago, succeeded in manufacturing a form of baryta which never oses its power of recovery. This baryta is prepared from the sulphate or carbonate by first converting it into the nitrate, and then driving off the nitric constituents by the application of heat. The plant which was first erected by Brin's Company was described and illustrated in our issue of the 21st October, 1887, and a full account of the most recent and improved form of the plant will be found in our issue of the 13th of December, 1889. After the works were erected it was soon found that a great loss of efficiency was occasioned by the retorts and furnace being subjected to two different temperatures alternately, and in seeking for a remedy they discovered that the same results could be obtained by maintaining a constant temperature of 1300° F., by forcing the air in at a pressure of 10lb. per square inch, and by subjecting the peroxide to a partial vacuum. Further improvements in the process were made by mounting the retorts vertically in the furnace and by conducting all the operations automatically. A full account of the automatic reversing gear will be found in our issue of the 13th of December, 1889. According to the most recent methods the air is purified of its carbonic acid and moisture by being passed through lime and caustic soda *after* it has been through the pump, so that the work required of the pump is decreased, and no traces of lubricants can now find their way into the baryta. During 1887 Brin's Oxygen Company sold about 140,000 cubic feet; but in 1889 this amount actually rose to 1,000,000 cubic feet. The author also gave a short description of the manufacture of the steel storing cylinders and of the method of charging them.

In the discussion which followed,

Mr. Joseph Adamson, who was engaged in the construction of the works of the Brin Company, said that at first the process was carried on in a laboratory fashion, and the designs were by no means calculated to obtain a practical success. However, after a year or two of experience, the managers became more of engineers than chemists, and now the plant was one of the simplest and most practical that he could well imagine.

Mr. R. A. Hadfield wished to know how much of the moisture of the air was removed by the lime and soda purifiers.

Professor A. B. W. Kennedy considered that it was the preservation of the same temperature in the peroxidation and deoxidation of the baryta that was the key of the success of the present process.

Mr. E. B. Marten, of Stourbridge, said that it would be instructive to hear a list of the various industrial processes in which the use of the oxygen had been found to be valuable. He also described an excellent model of the plant which was on view at a recent meeting of the Midland Institute at Birmingham. He had a great admiration for the skill with which the storing vessels were made, and considered that except for them the industrial application of the oxygen would be comparatively small.

Mr. C. E. Cowper, in referring to the storing of hydrogen by the Brin Company, said that the same steel vessels were formerly used for both gases, and that an explosion had been caused by oxygen being stored in a hydrogen cylinder. The greatest precautions should be taken to avoid such a mishap, and he hoped that the manufacturers were not unmindful of the matter. He also wished to know how long the storing vessels would last, and how long a charge would remain in without leaking away.

Mr. Schönheyder, while congragulating the engineers and chemists on the general efficiency of their plant, pointed out that there was still room for improvement as far as economy was concerned. For instance, a great amount of heat was wasted with the escaping gases from the furnace, and the very great heat which was acquired by the air as it passed through the retorts was also entirely lost. The fact that some time had to elapse before the oxygen came off pure in the deoxidising process was, in his opinion, far from satisfactory from an economic point of view, and was worthy of the consideration of the Brin Company.

Mr. Bernard Dawson corroborated Mr. J. Adamson's statement that the plant had been wonderfully improved since it was first laid down; in fact, it was gradually changed, until it was quite unrecognisable now to him who had helped to lay it down at the commencement. One question he would like to ask was whether the oxygen thus prepared had ever been tried in the manufacture of glazing pottery by the high temperature process.

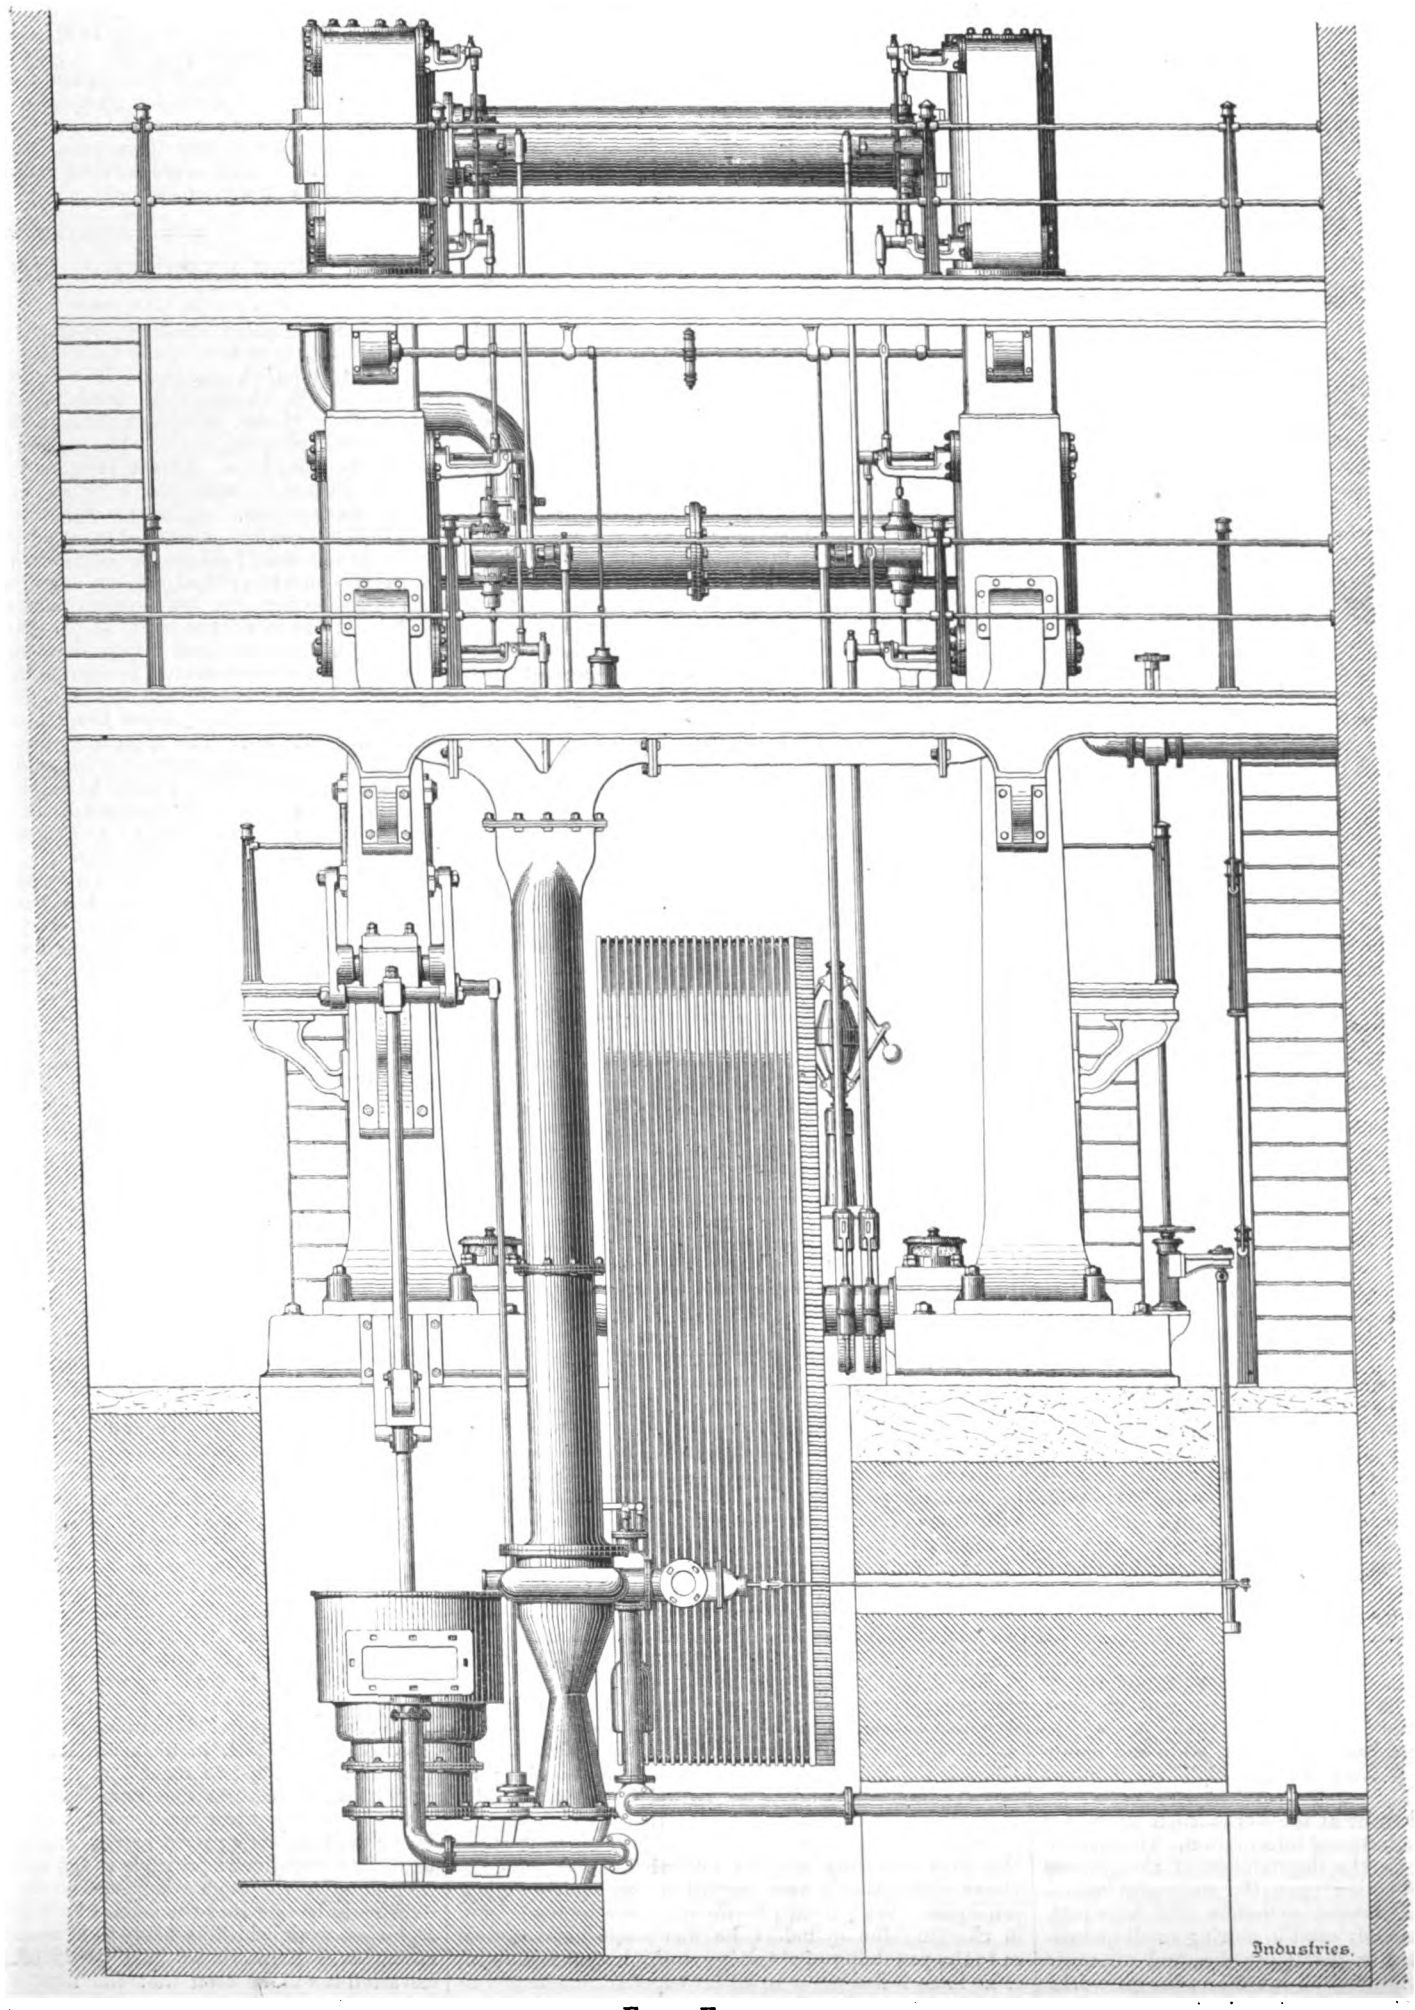
Dr. Thorne, the chemist at the works, then proceeded to give considerable additional information. The opinion of Mr. Marten as to the dependence of the process for its extensive application upon the successful manufacture of the steel storing cylinders was incorrect, for the cylinders were only used in storing small quantities for such purposes as limelights, &c., and wherever the use of the oxygen was at all extensive, the gas works or steel works at which it was employed would have plant erected on purpose for its manufacture, and then no compressive storing would be required. With regard to Mr. Cowper's question as to the danger of using the same cylinders for storing hydrogen and oxygen, he confessed that accidents had been caused by carelessness on the part of the company. They had so far recognised the necessity of preventing such occurrences as to adopt a left-handed screw-thread for the charging plugs of the hydrogen cylinders, and a right-handed thread for those of the oxygen cylinders, so that in future there would be no possibility of a mishap. The introduction of oxygen into metallurgical processes had a great future before it, and at the present time a number of very important experiments were being carried on with regard more especially to the reduction of the refractory ores. Mr. Hadfield desired to know what percentage of the atmospheric moisture was removed by the lime and soda. Usually there was about from 1 to 1½ per cent. of moisture in the air, and after it had passed through the lime and soda there only remained about ·02 per cent. This incompleteness of the removal of the moisture was, however, no drawback; indeed, it was apparently the cause of the difference in the practical results of Boussingault's and Brin's experiments. Boussingault, in his laboratory process, with a few feet of air, extracted every trace of moisture, and therefore the surface of the baryta became incapacitated for taking up oxygen after a few cycles of operations. With regard to Professor Kennedy's remark about the difference of pressure being the key to the success of the process, Dr. Thorne reminded the members that there was nothing extraordinary in the fact that at different pressures different chemical operations took place. When the plant was first erected, the peroxidation was conducted at a dull red heat and the deoxidation at a bright red heat, both at the same atmospheric pressure. It was afterwards found that the same effects could be obtained, but far more economically, if the temperature at which the two operations were conducted was kept constant at a little below the mean of the two, and if the pressure was increased for the first operation and decreased for the second. Theoretically, 1lb. of baryta would absorb and give off again 1¼ cubic feet of oxygen. With the old process, only about ·6 or ·7 cubic feet could be obtained practically, and even that took 3 hours. With the new process only ·1 to ·12 cubic feet could be obtained, but on the other hand the cycle of operations only took 15 minutes, so that the new process was in the end much more economical. In reply to Mr. Dawson, Dr. Thorne said that, as far as he knew, no experiments had yet been made with the high temperature glazes; but the glass blowers used the oxygen extensively in their blowpipes, and found, among other things, that they could work on lead glass with it without any fear of any reduction of the lead, and that the harder glasses could be melted as easily as the lead glass. He then described the Ramsgate gas purifying plant which we illustrated in Vol. VII., page 574, and afterwards proceeded to explain the action of oxygen in bleaching processes. The oxygen of the atmosphere was used for bleaching in those districts where fabrics are spread out in the open fields, but the process was very slow. Bleaching was, of course, identical with oxidation, but the free oxygen was not sufficiently alive to start its own work. Nascent oxygen is the most powerful bleacher, and it was this which was supplied by bleaching powder. When Brin's oxygen is used in conjunction with bleaching powder the nascent oxygen of the powder sets the other oxygen to work, and thus the efficiency of the mixture was very great. The saving of bleaching powder was sufficient to cause a very substantial reduction in the cost of the operation of bleaching. A large number of paper manufacturers and jute spinners had adopted this combined process, and there was every probability of its use becoming general. Another application mentioned by Dr. Thorne was in the purifying and boiling of oils for varnishes and for the thickening of them in the manufacture of linoleum. By the use of the oxygen the time occupied and the temperature were both reduced, and the great advantages entailed thereby would be appreciated at once by anyone who had worked with oils. Other applications were in the manufacture of vinegar and of sulphuric anhydride. Altogether he considered that the use of oxygen was only in its infancy, and that its future development would be marvellous.

Sir James Douglass gave some interesting reminiscences of the attempts of Goldsworthy Gurney and Faraday to use a jet of oxygen in conjunction with vegetable oils for the purposes of lighthouse illumination. Though the light was increased 2½ times, yet the price of oxygen in those days prevented its adoption. He had the greatest admiration for the mechanical skill exhibited by the engineers and managers of the works of the Brin Company, and he said that there were few places where things were carried on on such excellent principles. With regard to the oxygen compresser used in charging the cylinders, he was somewhat sceptical as to the possibility of obtaining the high efficiency given, as he himself had never in all his experience managed to obtain such satisfactory results.

Mr. Alfred Paget thought that Mr. Schönheyder was too severe in his criticisms on economy and waste, and he inquired whether it was a fact that the oxygen was found to be serviceable in removing fusel oil from spirits.

Mr. Murray, in replying to Sir J. Douglass, said that the company had four compressers continually at work, and that their efficiency was as stated in the paper. The first cylinder was double-acting, which might account for the good results. The compressing operation added 50 per cent. to the cost of the gas. Mr. Paget was right in supposing that the oxygen had a good effect in ageing spirits and wines. In reply to Mr. Cowper he stated that loss and leakage from the storing cylinders had given them a great deal of trouble, and that it arose entirely from the valves, which were always more or less porous. However, after a lengthened series of experiments they had adopted bronze three times run for their valves, and the oxygen could now be retained for six months without any sign of escape.

TRIPLE EXPANSION MILL ENGINE.



The engines of which we give illustrations on pages 124 and 125 have been made by Messrs. John Musgrave & Sons, Limited, engineers, Bolton, to the order of the Sun Mills Company of Bombay, who entrusted the work to Messrs. Musgrave through their agents Messrs. Sorabji, Shapurji, & Co. The makers have not been tied in working to a contract price, and therefore care has been taken to make the work as completely successful as was possible. A glance at the illustrations will show that the engines, instead of being constructed with three cylinders side by side, are arranged with four, so as to form two complete vertical tandem engines. The two lower cylinders form the low pressure, and are bolted to the top of the standards, while above them respectively are the high pressure and intermediate cylinders. The engines are thus connected to cranks placed at right angles to each other at each end of a straight shaft, which permits the rope-driving drum being placed in the centre of the engines. The high pressure cylinder is 16in. diameter, the intermediate 25in., and each of the low pressures 28in., all the pistons having a stroke of 3ft. 6in. The valves are of the Corliss type, worked by the well-known gear of the maker's, and those on the high and intermediate cylinders are directly controlled by the governor. The latter is an improved high speed one, and is also provided with Higginson's patent mercurial regulator (see description of this in *Industries*, Vol. VI. p. 340). The results obtained by the use of governors of this type, and the regulator, as shown by Moscrop's recorder, are highly satisfactory. It is claimed that with cylinders arranged in the manner described practically the same load is exerted on each crank, the engine is well balanced, and uniformity of speed is thoroughly attained. The standards are strong and substantial, and are constructed with large spreading bases, which are secured to a strong cast iron bed plate. The standards are made exceptionally long, and the result is that the engines are practically independent of any support in connection with the walls of the engine-house, while maintaining perfect steadiness and freedom from vibration. The high pressure and intermediate cylinders are carried by strong cast iron chairs bolted to the top of the low pressure cylinders. Stages on platforms are fitted to enable easy access being obtained to the various parts. The crank shaft is made of Siemens-Martins steel of high quality, the journals being 11in. diameter and 22in. long; the cranks are of best hammered scrap iron, and the crank pins are of mild steel, and are 6in. in diameter and 7½in. long. The crossheads are hammered scrap iron, and carry cast iron slippers of ample size. The piston rods are of mild steel, the high pressure being 3¾in. in diameter and the low pressure 4½in. in diameter, the pistons being fitted with Buckley's packing rings. Attached to the crosshead is a wrought iron lever, pivoted to the standard which drives the air pump rod. The air pump is vertical and single-acting, being 28in. diameter and 15in. stroke, and the barrel, bucket, and valve grids are of brass with india-rubber valves. The condenser is of the type usually adopted by the firm, which, while occupying a small space, gives good results in practice. As has been intimated, the power is transmitted by means of a grooved pulley 18ft. in diameter, and furnished with grooves for twenty-two ropes 1¾in. diameter, being built up with separate arms and boss, the rim being in segments. Arranged to work in connection with the wheel is one of Musgrave's patent barring engines, constructed upon their well-known principle to fall automatically out of gear after the engine is properly started. It only remains to be said that the makers have a reputation for high-class work which is likely to be maintained by the execution of the work we have described. In the side elevation it will be seen that the front cylinders have been removed for the purpose of showing the valve gear.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 129.)

PARIS, 4TH FEBRUARY, 1890.

IRON.—Business in iron continues on a very restricted scale here in Paris, and there is no prospect of much greater activity for some time to come. That prices are firmly maintained is due to the better state of things in the provincial markets. From all the chief centres of industry come reports of a steadily growing trade, and the prospect is brightened by important orders ahead, which cannot be long delayed. The success of the Fives-Lille Engineering Company in obtaining the contract for the construction of the proposed bridge over the Danube by the Roumanian Government has given a fillip to the markets of the Nord, and enabled the manufacturers more easily to obtain another advance in prices. The competing parties were the Fives-Lille Company, who tendered 7,657,617fr.; the Société Internationale de Construction at Braine-le-Comte, in Belgium, who tendered 7,958,949fr.; the Société du Creusot & M. Gaertner, who tendered 8,625,527fr.; the Société des Ateliers Eiffel, who tendered 9,017,082fr.; the Société des Anciens Etablissements Cail, who tendered 11,765,073fr.; and the Danube Bridge Company, in London, who tendered 17,630,084fr.

THE FOREIGN TRADE IN IRON.—The import trade in iron shows a considerable shrinkage for the year 1889, while the export trade exhibits an equally notable expansion. In the following figures the quantities in parentheses are those for 1888. Imports: Pig iron, 119,932 (136,613) tons; finished iron, 28,948 (33,843) tons; steel, 9,307 (8,473) tons. Exports: Pig, 120,000 (24,540) tons; finished iron, 67,556 (33,387) tons; steel, 36,323 (14,562) tons. The exports of pig iron in the last month of the year amounted to 40,000 tons.

THE VINTAGE OF 1889.—The official statistics of wine production in France in 1889, just issued by the Minister of Finances, show, for the vintage of that year, a yield of 23,223,600 hectolitres, a quantity that is less than that of the preceding year by 6,878,500 hectolitres, and below the average of the last ten years by 6,700,000 hectolitres. The Minister attributes the diminution partly to the phylloxera and partly to mildew and other maladies of the vine. The quality of the wine is described as excellent. The production of cider was some six million hectolitres below that of 1888, and ten millions below the average.

BERLIN, 3RD FEBRUARY, 1890.

RAILWAY ROLLING STOCK.—Makers of railway rolling stock were kept fully employed throughout 1889 by the large orders given out by the State Railways Department of the Government. The flow of orders from the same source continues, and in sufficient abundance to maintain the present activity at the works till the end of the current year. In the middle of last December contracts for the Breslau railway were entered into to the value of more than two million marks. On the 28th ult. further orders were given for the Frankfurt lines, and to-morrow, the 4th inst., the Cologne directorate will receive tenders for 2,810 goods waggons and trucks. As all makers are now fully provided for for many months to come, it is expected that in the course of the year large orders will be placed abroad.

THE GLASS TRADE.—The serious rioting which has taken place among the glassworkers on strike in Northern Bohemia has directed attention to the glass industry of that and its neighbouring locality. In consequence of changes in the export trade and keener competition brought about by the adoption of machinery, the wages of the glass cutters have fallen to only about one-fifth of what they were ten years ago. The evil is in large part due to the middlemen, who have the bead trade largely in their hands. The glass industry on Prussian territory is rapidly growing. At Weisswasser, as well as at Penzig and Rauscha, important works exist, and another large works is in course of construction, and still another is about to be commenced at Hoyerswerda. As an expression of discontent, and a protest against the high prices of glass brought about by the syndicating of the glass makers, a petition to the Minister of Commerce is being numerously signed, praying that the import duties may be removed or lightened for so long as the syndicate remains in existence. The imports of foreign glass in 1889 amounted to 241,018 cwt., the exports of German produce in the same period being 1,471,058 cwt. Of the latter quantity 237,212 cwt. were shipped to Great Britain. The syndicating of the glass bottle trade in England is regarded as favourable to the German export trade in those goods.

FLAX AND YARNS.—The yarn market at Trautenau has been better attended of late, and a fairly large amount of business has been done in linen and tow yarns. From Bielefeld we learn that the demand for flax and tow yarns has slackened. Prices, however, remain firm. The quantity of linen yarns imported into Germany in 1889 was 231,896 cwt. Of this quantity Great Britain furnished 22,214 cwt. The imports from Austria-Hungary amounted to 143,030 cwt. Sewing thread was imported to the amount of 8,864 cwt., nearly the half of which was derived from England.

GERMAN COMPETITION ABROAD.—The Germans are quick to profit by the faults and misfortunes of their rivals in trade. It seems that of late much of the mining machinery sent out from England to the gold fields of the Transvaal has failed to give satisfaction to the purchasers. The opportunity is being seized by the manufacturers of this country to send out properly qualified agents to South Africa, to endeavour to acquire a footing in the markets of those parts. In like manner, the ill feeling now existing against England in Portugal is being made use of to push forward German trade in the Peninsula.

EXHIBITION OF BEVERAGES.—An exhibition of German liqueurs, wines, beers, and mineral waters is to be held here from the 15th February to the 15th March, in the rooms of the new "Equitable Palast." The collection of exhibits will be a good one, and will probably attract a good many visitors from abroad.

THE ALKALI INDUSTRY.—The syndicate of the alkali works has issued its report of the sale during 1889. It appears that the deliveries of chloride of potash during the first half of 1889 amounted to 1,200,000 centners, and during the last half to 1,271,000 centners, as against 1,119,000 centners and 1,126,700 centners during the corresponding periods of 1888.

A SHIP CANAL FOR BERLIN.—The German Government have determined to construct a canal between Berlin and the Baltic. Herr Scheck has been asked to make surveys, &c., at the Stettin end of the canal. The canal is to accommodate the largest sea-going vessels.

THE POPP COMPRESSED AIR PATENTS.—The International Popp Compressed Air and Electricity Company was registered last week, with a capital of 1¼ million pounds. This company is constituted, among others, of the following:—Disconto Gesellschaft, Berlin; Dresdener Bank, Berlin; Oppenheim, of Cologne; Merck, of Munich; and Norddeutsche Bank, Hamburg.

TORPEDO BOATS.—The Portuguese Government have ordered five torpedo boats from Herr Schichau, of Elbing.

VIENNA, 3RD FEBRUARY, 1890.

THE IRON MARKET.—The iron market is very firm and the tendency in all branches is towards an increase. Last week the Styrian iron works increased their price of iron wire by 10fl. per ton. The Bohemian wire-nail syndicate announced an increase of 10fl., and the foundries one of 5fl. per ton in the prices of their products. Most of the railway companies in closing their accounts for the year found a considerable increase in their income during the last year as compared with 1888. They will pay higher dividends, and they will probably give out many orders for rolling stock. The Brünner Maschinenfabriks-Gesellschaft will hold their general meeting on the 25th February; at this meeting they will determine on an increase of the capital by at least 600,000fl.

THE COAL MARKET.—Great activity is displayed in the coal market. In the Western Bohemian district the brisk export continues, and last week the Saxon State Railways alone forwarded 80,606 tons of Bohemian brown coals, whilst a considerable quantity was shipped by the Elbe. The railways are taking advantage of the situation by increasing their tariffs. The Ministry recently granted the constitution of the new great Bohemian coal works company "Nordböhmische Kohlenwerks-Gesellschaft in Brüx," which has bought the largest collieries in the Brüx and Dux district.

BRUSSELS, 4TH FEBRUARY, 1890.

THE COAL MARKET.—The state of the coal market is undecided. On the one hand the producers are determined to sustain the prices, and on the other the buyers are holding back. The cessation of work at the Lens mines, a partial strike at some of the collieries, and the expectation of further strikes in Germany, all inspire the sellers with confidence in the maintenance of prices. The collieries have a large arrear of orders to complete, and they have not yet got into full working order after the strikes; for these reasons the price of coal is kept up. The effect of the strike may be seen from the returns of the amount of coal carried by the State Railways during January, which show a decrease of 10 per cent. as compared with the corresponding period of 1889.

THE IRON MARKET.—The iron market is in a much better position than one would have expected after the recent strikes in the coal trade. The prices are held firmly, and there is a great confidence in the future. Employment is assured for the whole of the year, and producers do not hesitate to arrange for long contracts. The buyers are holding off for a short time, as they expect that a possible lowering of the prices of coal may have a similar influence on those of iron. However, the chances of a fall in coal prices is very remote, and their anticipations are not likely to be realised. All the ironmasters are expecting a large demand from all quarters.

GLASS.—In window glass the dearness of raw materials and fuel maintains the tendency towards high prices. The American syndicate has decided not to buy from Belgian makers at rates above a certain maximum which they name, and the manufacturers, of course, are in serious difficulties on account of the great cost of production. They intend to hold a meeting shortly to determine on a line of action. Another glassworks has just been started at Brussels—viz., the Société Anonyme des Verreries de la Louvière. The capital is 125,000fr. in 250 shares of 500fr. each.

DÜSSELDORF, 4TH FEBRUARY, 1890.

COAL.—The question of the coal supply for the railways is engaging the earnest attention of the State railway authorities. One aspect of this question now under consideration has reference to the form of fuel to be used in future; whether the coal is to be burned in its natural state as heretofore, or in the form of artificially prepared blocks or briquettes. A number of specimen blocks prepared in different ways are undergoing the test of exposure to atmospheric influences. The agitation among the miners is again increasing, and it is feared that the Socialists will succeed in urging them to declare another general strike. The total production of coal in the Dortmund mining district in 1889 amounted to 33,851,190 tons, an increase of 2·1 per cent. relatively to the previous year. The number of hands employed at the end of the year was 121,200, against 111,198 tons at the end of 1888. The loss of the output in the second quarter of the year due to the colliers' strike in May last appears from the statistics of production to have been about 2,000,000.

IRON.—The business of the iron and steel markets remains without much alteration. The upward tendency of prices, occasioned by the prospect of dearer coal, continues distinctly marked. In most classes of iron the syndicate minimum is being oversold. The South-German rolled iron makers' syndicate has advanced its minimum to 192s. a ton at Neunkirchen. The total production of pig iron in Germany, including Luxemburg, in December amounted to 391,523 against 354,866 tons in the same month of 1888. The production of the year 1889 being 4,387,504 tons, the imports 339,246 tons, and the exports 156,434 tons, we have 4,570,316 tons as the quantity taken for the home consumption. The quantity of foreign iron imported is approximately equal to one month's production of the German furnaces.

AN IRON CHURCH.—A writer in the Leipsic *Tageb'att* describes an iron church which is approaching completion in the works of a Belgian engineering firm. The novelty of this structure, about which much interest is felt, lies in the fact of its being designed in the pure Gothic style to imitate stone. It is intended for erection in Manila, where earthquake shocks are frequent. It is 54 metres in length and 22 in breadth, the height to the roof of the nave being 20 metres. There are two towers to the structure, each 20 metres high. The total weight of iron is 1,600 tons.

LILLE, 4TH FEBRUARY, 1890.

IRON.—The recent considerable advance in the price of iron having been foreseen and discounted, has had no visible effect on trade. Consumers continue to give out their orders freely. Manufacturers are in some instances overwhelmed with work, having sufficient in hand for at least six months to come, and being pressed to deliver quickly. The scarcity of coal is everywhere felt. The prospect of another strike of colliers makes buyers desirous of getting their orders accepted as soon as possible. Bars and joists are quoted at the works 168s., and plates, for which the demand is strong, are hardly procurable at 192s. a ton.

TEXTILE MANUFACTURES.—The tone of affairs in the linen market has greatly changed in the last fortnight. The depressing languor in which the old year ended and the new year began has given place to at least relatively vigorous life, and manufacturers have come to take a cheerful view of the prospect. The turnover of last week was 16 per cent. greater than that of the week before, which was superior to that of the previous week by some 25 per cent. Buyers are continuing their operations, so that we may confidently look for a further expansion of business. The latest reports from Roubaix show a satisfactory state of things in the woollen trade of that district. The raw wool market is quiet, and the tendency seems to be towards slightly lower prices.

FLAX AND YARNS.—The situation has not greatly changed in the course of the last week. All the markets of Flanders are now well supplied with home-grown flax, and the demand is active. The better qualities are much sought after, and prices have advanced a little. The market for Russian flax is more active, but the amount of business done is small for the season. Dealings in yarns are mostly limited to the wants of the moment. Prices remain unchanged. The demand for jute yarns continues active. Cotton yarns are a little stiffer in price, and business is in consequence somewhat restricted.

AMSTERDAM, 3RD FEBRUARY, 1890.

RAILWAYS.—The Dutch Government has submitted to the States-General Bills for the approval of the agreements successfully made with the Dutch-Rhenish Railway Company, the Holland Railway Company, and the State Railways Company. The chief contract, to which I have already referred in these columns, is the one for the purchase of the Dutch-Rhenish Railway by the State, and the two other agreements are merely consequences of the first. Having bought the Dutch-Rhenish lines, the Government had to decide about the working of them, and as in Holland the State does not work the railways it owns, the choice lay between the Holland Railway Company, the oldest in the kingdom, and the State Railways Company, which works most of the State railways. The Government has decided to divide the purchased railways between the two companies for working in such a manner as to attain the chief object in view—viz., the doing away of excessive

Digitized by Google

competition and the bringing into closer harmony of the different sections, particularly in relation to foreign railways, and the international train service. For this reason, too, considerable improvements will be carried out on the lines of the Dutch-Rhenish Railway, and a short loop line is to be constructed at Rotterdam to connect the Dutch-Rhenish with the Holland Railway, thus ensuring a through service of trains that has hitherto been wanting, *viâ* Rotterdam east and westward. The State is to pay 1,200,000 guilders—say, £100,000—for this connecting line, and 800,000 guilders—say, £75,000—for the improvements above mentioned. The purchase money payable to the Dutch-Rhenish Railway is 63,415,537 guilders—say, a little over £5,000,000. Some £2,000,000 of this total is for loans of the railway company, and the remainder for its share capital, to which must be added an amount of over £500,000 to be paid to the Dutch-Rhenish shareholders by way of premium for immediately selling a property to the State which could not be purchased compulsorily before 1898, that being the legal term of the concession. It has been argued that the Government could have made a better bargain by waiting until 1899, but, in the *exposé des motifs* which accompanies the Bills the Government explains that there were many reasons for acquiring the Dutch-Rhenish system now, and making suitable arrangements for working it—arrangements that, perhaps, could not have been perfected in 1899, or could only have been perfected then under less favourable conditions. Moreover, the ease of the money market and the present high prices of Dutch State securities will enable the Government to borrow the necessary purchase money at a low rate, whilst a totally different state of affairs might exist in 1899. The Dutch-Rhenish shareholders will virtually receive £123 for £100 stock, which does not appear excessive. In order to pay for this bargain, the State will have to contract a new loan of 47,523,000 guilders, close upon £4,000,000, in 3 per cent. bonds. The total amount payable is 65,415,537 guilders, but this sum is diminished by 20,267,847 guilders, being the estimated value of certain assets, mainly the rolling stock of the Dutch-Rhenish system, valued at about £750,000, and shares in the Leyden-Woerden and Utrecht-Kampen railways, which shares were in the possession of the Dutch-Rhenish Company, but will pass now into the possession of the State, together with the net receipts of the current book year above 5 per cent. The real amount payable is, therefore, 45,147,689 guilders, or 47,523,000 guilders in the shape of a 3 per cent. State loan at 95. This constitutes the most important railway combination in Holland ever since railways began there. The capital invested by the State in railways will now exceed £20,000,000.

ELECTRIC LIGHTING AT DORDT.—The town authorities at Dordrecht have signed a contract for the electric lighting of the public streets. The installation will be underground as far as the wires are concerned. The estimated cost is £13,000.

ELECTRIC TRAMWAY AT SCHEVENINGEN.—The first electric tramway of Holland will be opened in March next. It runs from the Hague to Scheveningen, the distance traversed being about four or five miles.

ACCIDENTS IN FACTORIES.—The public meeting at the Hague on Friday to promote the formation of an association of factory owners, with a view of minimising dangers to the lives and limbs of workmen in the factories of Holland, was a decided success. Some sixty factory owners were present. It was decided to constitute the association, a committee being appointed to draw up its articles, after which the King's sanction, necessary to constitute a legal body in Holland, will be asked.

THE GOLDFIELDS OF GUIANA.—I have already alluded to the boundary dispute which had arisen between the French and Dutch Governments in Guiana, a dispute that mainly relates to the possession of the Marowyne goldfields. After a brisk diplomatic correspondence, it had at last been decided to appeal to arbitration, but the first attempt to obtain a suitable arbitrator has signally failed, the Czar of Russia having refused to act in that capacity. It is stated in Government circles at the Hague that the refusal of the Russian Emperor is the consequence of certain conditions to which the Dutch Government had made the arbitration subject. France, on the other hand, had put forward no such conditions.

COPENHAGEN, 1st February, 1890.

SPIRITS IN SWEDEN.—The Carlsbaum Spirit Refining Company, at Carlshaum, Sweden, has, during the past year, refined and re-exported not less than 18,428,000 normal litres of spirit; in hand at the end of the year there was close upon 13,000 000 normal litres.

AN ICE BREAKING STEAMER.—The ice breaking steamer "Martaja," built at Finnbodazand, Sweden, for the Finnish Government, was launched recently. This is a very powerful ice breaker, being intended to force a thickness of 25in. ice. She will be stationed at the Hangö Harbour. Her principal dimensions are: Length, 160ft.; breadth, 37ft.; and depth, 20ft. The engine is on the compound system, and indicates 1,200 h.p. There are four independent boilers made of best Swedish Siemens-Martin boiler plate. The ice belt is of best Surahammer puddle plate, and the vessel altogether is built of the best possible material.

BEETROOT SUGAR MANUFACTORIES IN SWEDEN.—The manufacture of sugar from beetroot, which has become such an important industry in many countries, is rapidly increasing in Sweden, and, amongst others, a very large factory is approaching its completion at Helsingborg. The buildings are being roofed. The refinery will be ready about July, and the whole establishment will, barring accidents, be ready for the autumn's campaign. The new factory will have a capacity of about 5,000cwt. beetroot per day, or about 600,000cwt. during the four months of the "campaign." The pecuniary results seem exceedingly satisfactory to the growers. The same company is also building a sugar factory at Engelholm. During the last the four beetroot sugar manufactories at Arläf, Staffanstorp, Säbzholm, and Trelleborg, which are all in the same district, handled altogether 108,222 tons of beetroot.

SWEDISH STATE RAILWAYS.—During the year 1889 the section on the main line Langsele-Vännäs has been entirely finished between Langsele and Skorped, and leveling and other work done between the latter station and Anundsjö, so that the portion Langsele-Anundsjö, about 82 kilometres, is ready for traffic. Rails have since been laid for another 9 kilometres. The total length of the Swedish State railways was at the beginning of last year 2,531 kilometres, and on December 31st 2,613 kilometres. Takings amounted to about 21,800,000kr., of which 6,500,000kr. have been handed over to the Exchequer.

TIMBER TRAFFIC IN SWEDEN.—The opinion that the timber would be mostly floated down the rivers rather than forwarded by rail does not seem unlikely to alter. It was thought that the railways would only serve the timber traffic inasmuch as conveying it to the rivers was concerned, but the State railways think they can carry timber the whole length to the coast, and that this means of transport will in many cases be preferred to floating it down. It would, of course, be necessary to construct side lines from the trunk railway (the question is here more especially about Norrland) to the coast, where sufficient accommodation for further working the timber would have to be procured. The more important Swedish industries are altogether being more and more rationally dealt with, and are undoubtedly entering upon a more satisfactory stage. The question of timber is, of course, a very important one, and it has recently been argued with considerable weight that the present reckless and often aimless cutting down of Swedish forests should be put a stop to, and the matter dealt with and properly controlled and regulated through some Parliamentary measure. Along with a better handling of the raw materials in Sweden, such as timber and iron, runs an increased amount of manufacture within the country, both for home consumption and export, attended, as far as can be judged at present, by satisfactory results. As a new venture may be mentioned the manufactory at Ljungby, close to Sunnerbo, for wooden shoes and other articles of wood, such as lasts, &c. The works have secured the patent rights for Sweden for some perfected machinery, and the whole seems to be arranged in a thoroughly business-like manner.

MADRID, 3rd February, 1890.

THE NOXIOUS FUMES QUESTION—The Council of Estate has declared that it was within the powers of the Government to issue the decree prohibiting the open-air calcination of iron pyrites in the province of Huelva. This decision against the Rio Tinto Company greatly complicates the affair, and technical men cannot understand why this company is so reluctant to apply some other and more satisfactory process which would keep them in peace with the Government and with the country in general.

RAILWAY FROM LA ROBLA TO VALMASEDA.—An unsuccessful attempt has been made at Bilbao to raise the capital for the railway which it is proposed to make from La Robla to Valmaseda, near Bilbao. This line will pass through various coal districts.

PIG IRON AT BILBAO.—Bilbao pig iron, which has been selling at 80s. per ton, is to be raised to 84s. The buyers are not accustomed to frequent changes of prices, and they think that the prices ought to remain the same for years.

BLAST FURNACE OF QUIROS.—The blast furnace of Quiros, in Asturias, after having been improved, was put in blast last week. It is a very small one, and will hardly produce more than 200 tons per week. The Mieres Company, to which it belongs, have been limited in their make of rolled iron by want of pig. This furnace has one of the cheapest supplies of iron ore of about 38 per cent. of metallic iron.

NEW YORK, 24th January, 1890.

THE COAL TRADE.—The anthracite trade remains very dull for domestic sizes. There is no demand for these sizes, and it is not believed that any concession in price would improve the market. There is a good demand for manufacturing and steam sizes, which is likely to continue. What the trade needs is some cold weather or a restriction of tonnage. The output is considerably lighter than it was, but it is still enough to keep the trade in a bad state. Another depressing influence is the competition between the different companies for the large contracts usually given out af this time of year. The Reading Company is reported to have taken the contract to supply the Philadelphia Waterworks with 66,000 tons of pea coal at $2·03 per ton. As the tolls are $1·40 this contract means 63c. at the mines, and probably does not leave over 11c. to 13c. for the mining company. Prices are being cut in New York, and there are reports of sales of stove coal at something like $1 below circular rates.

GROWTH OF THE NORTH-WESTERN STATES.—Some of the evidences of the great growth in the new North-West are given in the record of the Northern Pacific Railroad Company, which gives a synopsis of the business done during the four years from 1886 to 1889. The gross receipts have increased from 11 to 19 million dollars. The number of passengers carried in 1889 exceeded those carried in 1886 by just about one million. The quantity of freight carried one mile increased from 500,000,000 to 900,000,000 tons. The growth of traffic has resulted in a good increase of net income. The expenses have not kept pace with the gross receipts because of the better-fitted trains, although the rates for both passengers and freight are less now than four years ago.

A LARGE ARTESIAN WELL.—A large Artesian well was put down in Woonsocket, Dakota, a short time since, and, after repeated attempts, the water has just been got under control. A lake, covering some forty acres, had been formed by the escaping water, and a dense fog is constantly rising from the warm water. Half the pressure is now turned on, and the water runs through a 6in. pipe and the force is sufficient to form an unbroken stream of 150ft.

NAVAL AFFAIRS.—The actual horse-power performance of the new cruiser "Baltimore" on her recent trial trip was made known on the 19th inst., by the promulgation of the report of the trial board. The aggregate indicated horse-power was 10,064. This gives the Cramps a power premium of $106,400—*i.e.*, $100 for each horse-power in excess of 9,000. The ship has already been placed in commission, and steamed to Norfolk to receive her armament. A special meeting of the Senate Committee on Naval Affairs was held on the 15th to hear the views of the Naval Board of Policy appointed last summer by the Secretary of the Navy to formulate and report a plan for the building of a navy to be commensurate with the dignity and power of the nation. They approved in general terms the Bill introduced by Mr. Hale, authorising the construction of eight battleships of from 7,500 to 10,000 tons each, two armoured coast defence vessels, three gunboats of from 800 to 1,200 tons each, and five torpedo boats. This Bill appropriates five million dollars for construction and two millions for armament. The Policy Board will recommend in their report to the Secretary the construction of one hundred and two vessels of all classes; these would be built, according to the plan of the Board, in fourteen years, and will cost together with their maintenance during the fourteen years $280,000,000, but it is not at all likely that Congress will authorise any such extensive plan.

IMPORTANT RAILWAY MEETING.—There is to be an important meeting of railroad men in New York this week. Representatives from roads in all parts of the country will be present, and the object of the meeting will be to devise plans to promote harmony and maintain rates. There has been a good deal of trouble among the Western roads lately, and it is generally recognised that the Inter-State Railway Association has outlived its usefulness. The object now is to form a railway clearing-house, and the idea will be not to make a railroad combination, but a clearing-house, or several of them, taking in certain prescribed terrtorial limits, with clerks to audit the accounts, under established tariffs, and make the necessary settlements with adjoining lines.

THE IRON AND STEEL TRADE.—The events of the past week have not been particularly encouraging to the iron trade. Prices have become very irregular, and the chances of a further advance are small. Sellers are inclined to wait developments, but it is probable that for good-sized lots concessions could be obtained. There is no material change in pig iron. The local furnaces are well sold up, and can afford to wait, but Southern irons are being offered in this market at less than local brands. This, if continued, can only lead to lower prices, and with the continually increasing output it will be difficult to maintain present rates. Prices are nominally $20, $19, and $18 for the three grades at tide; favourite brands bring a little more. The manufactured iron business is dull, and prices are somewhat easier, and concessions are not hard to obtain on good orders. Prices are 1·95c. to 2c. per lb. for bars, 2·35c. to 2·40c. for plates, 2·30c. to 2·35c. for angles, with about 25c. additional for steel. The steel rail market is firm, with an increase of from 50c. to $1 per ton. $36 at mill is now the usual quotation, and nothing is to be had at less than $35 50. The mills are all full of work, and therefore in good condition to maintain prices.

COMMERCE OF PHILADELPHIA.—The report of the value of exports and imports and duties collected at this port during the past year shows a slight increase over last year, the total imports amounting to $50,987,102, for 1889, and $45,020,132 for 1888. Exports during the same year amounted to $31,335,645, and $28,012,879 for the two years, while the duties collected amounted to $22,612,956·17 for 1889 as against $20,587,684·17 for 1888.

FLOUR FIRMS COMBINE.—At a meeting held in Milwaukee on the 9th inst., a combination was formed among the seven great flour mills of that city, involving $5,000,000 capital, and an annual output of nearly 1¼ million barrels of flour. The combination was made to meet the threatened competition of the Minneapolis mills. Milwaukee stands third in the country as a flour-producing city, having marketed 1,265,833 barrels of flour during the past year.

INTER-STATE LAW AMENDMENTS.—In their annual report, the Inter-State Commerce Commission make recommendations looking to the amendment of the law, so as to make both inter-State and international roads subject to the provisions of the Act; to better provide for through traffic and through rates over connecting lines; and allowing the free transportation of persons injured in railroad accidents, and of the families of railroad employés.

IMPROVED BOILER FLUES.

CONSTRUCTED BY MR. DAVID MIDGLEY, WOOD NOOK IRONWORKS, LEEDS.

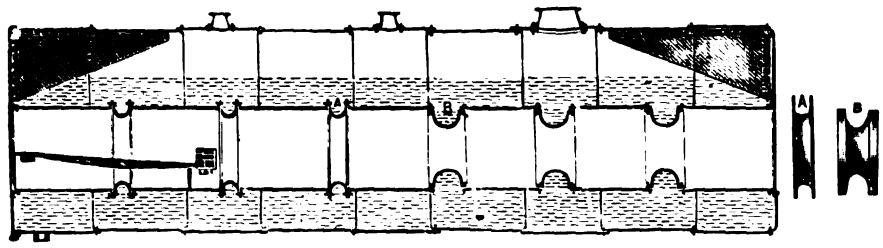

FIG. 1.

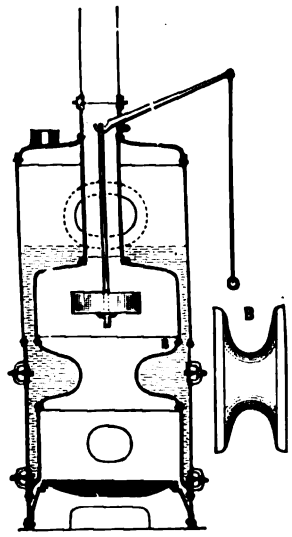

FIG. 2.

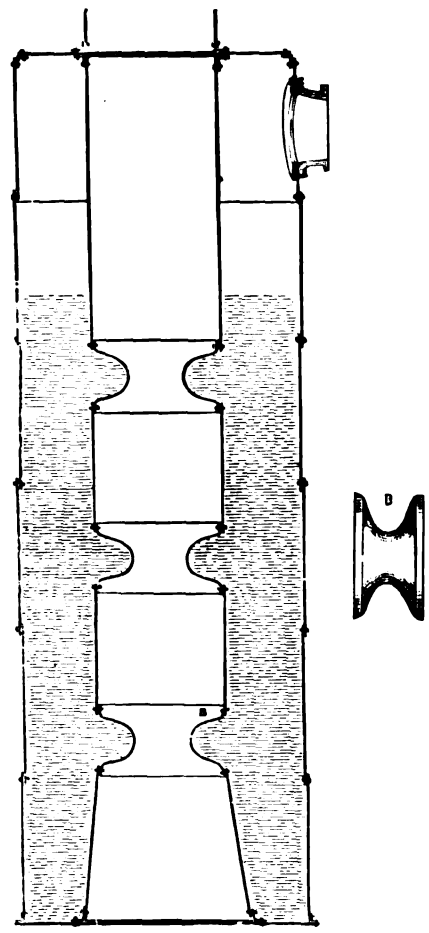
IMPROVED BOILER FLUES.

WE illustrate herewith a method of strengthening boiler flues, which has lately been adopted by Mr. David Midgley, Wood Nook Ironworks, Stanningley, near Leeds. Instead of using cross-tubes of the Galloway type, or external corrugations, or rings, now so general, Mr. Midgley inserts a few of what he calls "inverted expansion rings (A, B) into the length of the flue. The flue thus appears to have internal corrugations, and these extra surfaces thus gained are very effective as heating surface. The rings also will stand great strain, and therefore save the ends of the boiler to a large extent. They may be applied to vertical boilers, as in Figs. 2 and 3, or to Lancashire or Cornish boilers, as in Fig. 1. In practice Mr. Midgley finds that in boilers constructed on this plan, one ring is equal to three cross-tubes, as far as economy of steam and coal is concerned, and their general working is giving entire satisfaction.

THE BOILER EXPLOSION AT BENNERLEY FURNACES.

IN view of some probable legislation during the coming Session in connection with steam boilers, we give below an abstract of the result of the formal inquiry made on the 27th ult. at Ilkeston by the Board of Trade Commissioners—Mr. Howard Smith, barrister, and Mr. W. Lang, consulting engineer—into the cause of a boiler explosion at the Bennerley Furnaces on the 23rd November last. We do not care to trench upon the official report by giving the evidence of the various witnesses, and will simply give the substance of the Commissioners' opinion, as stated by Mr. Howard Smith when reviewing the evidence. From this it will be seen that, although the boiler exploded and caused the death of two children and injury to three women, the Commissioners held that no one was to blame—neither the boiler maker, the boiler owner, the boiler attendant, nor the insuring company. We therefore commend the following abstract to the consideration of those engaged in preparing additional legislation for steam boilers and steam users.

In reviewing the evidence, Mr. Smith said that he and Mr. Lang were of opinion that the iron of which the boiler was made was of good quality, and that the boiler was properly constructed. They considered the boiler would not have undergone a satisfactory examination unless it was tested by hydraulic pressure before it left the maker's works. Whether it was so tested or not in this case they were not able to say. They were



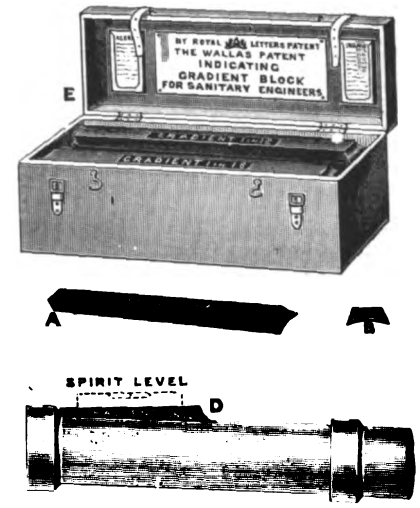


FIG. 3.

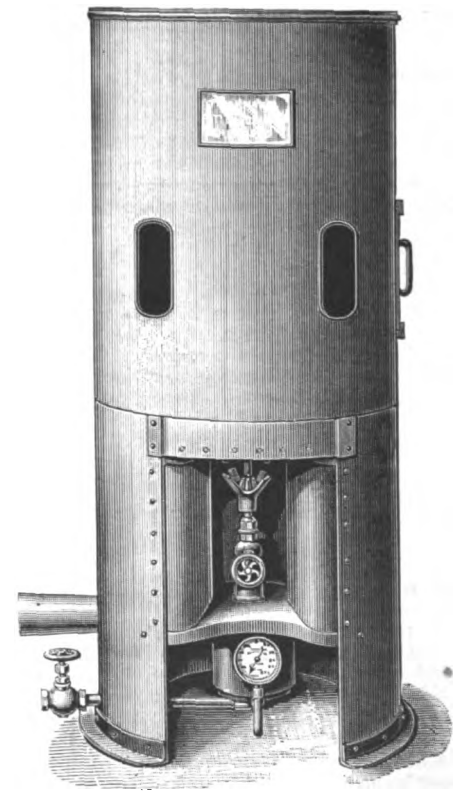
satisfied that Mr. Young, the inspector to the insurance company, made a thorough examination of the boiler on April 12th. They thought that at that time no repairs were necessary.

Mr. Smith remarked that they were further of opinion that the water which was put into the boiler was of proper temperature. They had come to the conclusion that the explosion was due to the flaw which was in the plates along the rivets of the circumferential seam which ripped right round the boiler. It was impossible for them to say how long the seam rip had existed. They did not agree with the evidence of one of the witnesses that probably it occurred on the day the boiler was filled. They thought that probably it had existed for two or three weeks, but they had no reason to suppose—in fact, the evidence was to the contrary—that it existed at the time when Mr. Young made his examination on April 12th. They had great pleasure in acquitting Mr. Young of any blame whatever. With regard to whether the owner was to blame, they were glad to say that the management of this particular boiler was very different from the management of other boilers which they had had to inquire about recently. It seemed to them that Mr. Davis, the owner, had done all that a man ought to have done, having taken great pains to see that a proper examination was from time to time made. It was probable that had a detailed examination been made when the boiler was laid up a day or two before the explosion the rip would have been discovered; but it was not the ordinary time for laying it up for that purpose, and in justice to the men it should be stated that they had no suspicion that the boiler was not in proper working order. To the question, which he understood would only be put formally, as to whether the owner was to blame, their answer was in the negative. They did not think that any blame attached either to him or Mr. Young. As to whether the company were justified in insuring the boiler without having first made an examination of it, they had already said that they hoped that in every case before a company took the risk they would make a proper inspection of the boiler In this particular case, however, there were, they thought, good reasons why the insurance was accepted. The boiler had been previously insured with the company, and all the facts in connection with it were known. In regard to the question whether the company were justified in taking the risk without making a further examination, their answer was that on the whole they were justified.

GRADIENT INDICATOR FOR DRAINS.



MR. I. C. WALLAS, Kilburn, London, has recently brought out a simple and inexpensive indicating block, illustrated herewith, for use in laying drain pipes to any desired gradient. A different block is made for each gradient, and it fits over the upper surface of the pipe.

A spirit level is placed upon the top of the block, and when this level is horizontal the pipe is at the gradient required. It will be seen that the whole length of a drain can be tested for gradient with the greatest ease, and by means of the blocks the pipes can be laid to give a definite outfall.

SAND BLAST FOR CLEANING CASTINGS.

WE illustrate below an apparatus which has been designed by Tilghman's Patent Sand Blast Company, Bellefield Works, Sheffield, for cleaning brass, iron, and steel castings, and other metallic surfaces by means of a sand blast. Decided advantages have been found in using the sand blast for cleaning ornamental and cored castings where there are a great many hidden surfaces, on account of the rebounding of the grains of sand in all directions. The slightly roughened surface which the

blast produces is well adapted for the adherence of zinc and plating metals. It has been found that the action of the blast does not interfere with the quality of the metal. In working with this apparatus the casting is introduced through a door at the back, and the workman places his hands through the two oblong openings in the front, and thus holds the article. A glass window is arranged above the oblong holes for him to look through to see the progress of the operation. With larger castings a chain is used for supporting them, and the workman simply guides them.

SHIPBUILDING NOTES.

On the 18th ult. the s.s. "Sandfield," a new vessel, 275ft. by 30ft. 6in. by 20ft. 6in., built by Messrs. Withy & Co., of West Hartlepool, for Mr. Frederick Woods, of London, left West Hartlepool for her trial trip. Her engines are of the triple expansion type, and have been built by Messrs. Blair & Co., of Stockton-on-Tees.

On the 20th ult. Messrs. E. Withy & Co. launched from their shipyard at Hartlepool a screw steamer built to the order of Mr. G. Steel, of West Hartlepool. She is 300ft. long, and of large deadweight carrying capacity. She has a raised quarter-deck, long poop, topgallant forecastle, and cellular bottom for water ballast, and is fitted with steam winches, steering gear, and all the latest improvements. Messrs. Richardson & Son, of Hartlepool Ironworks, will provide the engines. She was named "Blenheim."

On the 21st ult. there was launched from the yard of the Tyne Iron Shipbuilding Company, Limited, of Willington Quay-on-Tyne, a steel screw steamer which has been built to the order of Messrs. Burrell & Sons, of Glasgow. She is of the following dimensions:—Length, 300ft.; breadth, 41ft.; depth, 22ft. This steamer has water ballast right fore and aft on the cellular system, and is fitted with all modern improvements for the rapid loading and discharging of cargo, including large donkey boiler and four double-cylindered steam winches, and has direct-acting steam windlass, steam steering gear by Messrs. Muir and Caldwell, and Hastie's screw gear aft. The engines, which are to be supplied by Messrs. Wigham Richardson & Co., are of the triple expansion type, having cylinders 23in., 37in., and 62in., by 42in. stroke, with two large boilers working at 160lb. pressure. On leaving the ways the vessel was named the "Strathdon."

Notices of Meetings.

THIS WEEK.

The Institution of Civil Engineers.—Students' Meeting, Friday, February 7th, 7.30 p.m. Paper to be read: "Reclamation of Land on the River Tees," by Colin P. Fowler, Stud.Inst.C.E. Ordinary Meeting, Tuesday, February 11th, 8 p.m. Paper to be further discussed: "Bars at the Mouths of Tidal Estuaries," by W. H. Wheeler, M.Inst.C.E.

NEXT WEEK.

Society of Arts.—Monday, February 10th, 8 p.m. Cantor Lectures: "The Electromagnet," by Silvanus P. Thompson, D.Sc., M.I.E.E. Tuesday, February 11th, 8 p.m. "Cast Iron and its Treatment for Artistic Purposes," by W. R. Lethaby. Wednesday, February 12th, 8 p.m. "Modern Improvements in Facilities for Railway Travelling," by George Findlay.

The Institution of Electrical Engineers.—Thursday, February 13th. "The Theory of Armature Reaction in Dynamos and Motors," by Jas. Swinburne.

The Junior Engineering Society.—Friday evening, February 14th. "Newspaper Printing Machinery," by Mr. P. Marshall; "Cylinder Ratios and Heating Surface in Marine Engine and Boiler Efficiences," by Mr. R. L. Newman.

PRICES CURRENT, 5th February, 1890.

Quotations at per ton, unless otherwise specified.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals.—Caustic soda continues in short supply, and prices are advancing strongly under the influence of an improved inquiry. Bleaching powder is a turn easier for both present and forward delivery. All qualities of soda ash are tending upwards; ammonia alkali just advanced 7s. 6d. per ton. There is very little inquiry for carbolic acids, and prices of crude and crystals continue to droop, liquid, however, remaining steady. Benzoles are in good demand at the advanced rates, and solvent naphtha has a steady outlet. Sulphate of ammonia is again lower. Acetates of lead are steady. Acetate of soda, which has been persistently depressed, is receiving more attention.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

Paris, Feb. 6.—*Iron.*—The market is steady, and prices are firmly maintained. Bars and joists, 170s.; old rails scarce at 78s. In the Haute-Marne very brisk demand for wire, wire-nails, and chains. Founders less busy. In the Nord recent advance well established. Demand active, but production hindered by want of coal. In Loire-et-Centre prices are higher. Base price of bars 168s. a ton.

Metals.—The "bull" operations in copper seem to have nearly played themselves out. Chili bars same as last week. Best selected a little lower. The market is heavy for tin, at three or four points below last week's prices. Lead is again lower. Spelter, too, has receded a point. Consumers are buying as little as possible.

Berlin, Feb. 6.—*Bourse.*—The decision of the Westphalian colliers to postpone the general strike till after the elections created a scare among the "bears" in industrial securities. The buying back which resulted from it not only checked the downward movement, but brought about some recovery in the market. The change is, however, due wholly to speculative dealings. Investors have lost confidence, and stand aloof. The market is weaker to-day on receipt of unsatisfactory news of the Scotch iron market.

Metals.—Speculative business in metals is just now confined within very narrow limits, and the buying on the part of consumers is limited to the requirements of the moment. The tone of the market is, however, unmistakably firm all round. Mansfeld refined copper, £61 to £62 10s.; Banca tin, £103 to £106; Clausthol refined lead, £16 to £16 10s.; ordinary Silesian spelter, £26 to £26 5s. Antimony regulus a little dearer.

Breslau, Feb. 6.—*Coal.*—The colliery owners have again advanced their prices. Large and round are quoted 8s. to 9s.; nuts, 7s. 3d. to 8s.; small, 4s. 7d. to 5s. The demand is very active. The output of the pits is said to be kept 25 per cent. below their possible production by the want of a sufficient number of railway waggons. The miners are now working contentedly.

Iron.—The iron market is strong and active. The brisk demand for pig and the absence of stocks keep prices very firm. Forge pig is scarce. The demand for scrap is constantly increasing. In the finished iron and steel market a large business is being done in plates and joists. Prices are unaltered. Founders report increasing activity in their branch of the industry. Export orders are more numerous.

Zinc.—The supply of spelter barely keeps pace with the demand. The state of the market is significantly indicated by the fact that it finds its way immediately into second hands. Best W. H. spelter is quoted as high as £25 2s. 6d.; other refined brands a little less. The new zinc rolling works at Myslowitz are approaching completion.

Düsseldorf, Feb 6.—*Coal.*—Though the miners have agreed to wait till March 1st before proceeding to extremities, it is becoming every day more certain that next month will bring another interruption of the output of coal. In view of this contingency manufacturers here are contracting largely with Belgian producers. The coal merchants seem disposed to advance their rates. The attitude of the colliers occasions great anxiety.

Iron.—The business of the iron market has perceptibly fallen off in volume. Buyers manifest less confidence in the stability of the situation, and hesitate to enter into fresh contracts. Nevertheless prices are firm all round, and for some classes of iron have advanced slightly since yesterday's opening hour. Spiegel pig is in better demand for export. It is announced that the makers are fully sold ten months forward. Forge pig, 93s. and 94s.; finished iron and steel unchanged; rolled wire less inquired for.

Prague, Feb. 6.—*Glass Workers' Strike.*—The glass workers out on strike threaten to burn down the works if foreign workmen are engaged to fill their places. The rioting continues. Public sympathy is in favour of the men, whose wages have been cut down to starvation point. Indignation is strong against the middlemen. Quiet can be restored only by a complete change of the basis on which the trade is now carried on. Market wholly disorganised.

Hamburg, Feb. 6.—*Nitrates.*—There is no improvement in the market for Chili saltpetre, and last week's prices are with difficulty maintained. Spot, £8 2s.; to arrive in March, £7 10s.

Charleroi, Feb. 6.—*Iron.*—Confidence is being gradually restored. Buyers are giving out their orders freely at the prices now current. Pig iron is being sold at the prices of the day for distant future delivery. Ordinary forge, 72s. The market is active for finished iron. No. 2 bars, 152s. at works and f.o.b. Antwerp; joists, 144s. and 148s. Plates No. 2 are quoted from 176s. to 180s.; steel plates, 208s.; steel rails f.o.b. Antwerp, 140s. a ton.

Ghent, Feb. 6.—*Flax and Yarns.*—An abundance of home-grown flax on offer, and a moderate volume of business transacted. Prices unchanged. Russian flax more inquired after. Demand slack for tow and linen yarns. Cotton spinners are asking higher prices for yarns; but the attempt to keep pace with the advance in the raw material has checked business.

We have received two catalogues from Messrs. John Birch & Co., engineers and merchants, Liverpool. One of them is called "Railroads and Rolling Stock," and it gives almost every information which could be desired as to the cost of plant and material for all kinds of lines. The other is called a "Representative Catalogue of Machinery, Machine Tools, and Engineering Material," and we think it well deserves its name.

HOME INDUSTRIES.

LONDON 6th February, 1890.

The Money Market.—There is virtually no change in the position of the money market. Though the conditions which brought about the stringency have somewhat improved, the Bank of England maintains its precautionary attitude and still manages to control the policy of the market. The foreign exchanges have begun to move in favour of this country, with the effect of making money a little easier, but there is not yet any general disposition towards ease. In point of fact no one ventures to forecast the immediate future of the money market. That being so it is not remarkable that business remains dull on the Stock Exchange. The instances of activity are isolated and arise from special causes. The slight improvement in the monetary conditions has told favourably on Consols. Foreign bonds stand fairly well, renewed favour being shown towards Turkish and Egyptian issues. The publication of the programme to be followed by the Peruvian bondholders under the Grace Contract has led to an improvement in Peruvians. Eight per cent. dividends declared on North-Western and Great Western stocks have been insufficient to keep up the "heavy" market, and in general home railways have been depressed. American railways have been less in request than last week, although New York still takes a hopeful view. The Mexican Railway maintains and improves on its recent recovery. Nitrate and mining securities are in undisguised disfavour.

Companies.—The following companies have been registered since our last report:—John Corrigan & Co., Ld., with a capital of £10,000, to carry on the business of engineers and machinists; The Glass Bottle Industries, Ld., with a capital of £1,400,000; Grindley & Co., Ld., with a capital of £20,000, to carry on the business of distillers of naphtha, tar, resin, &c.; Multiple Automatic Co., Ld., with a capital of £50,000; The Lichfield Brewery Co., Ld., with a capital of £250,000; The Clitheroe Salford Bridge Mill Co., Ld., with a capital of £2,000; Norwich Electricity Co., Ld., with a capital of £50,000; The Automatic Amusement Co., Ld., with a capital of £3,100; The Universal Electric Light and Power Trust Corporation, Ld., with a capital of £5,000; The Costa Rica Syndicate, Ld., with a capital of £250,000, for the purpose of constructing and working railways, &c.; The Central Argentine Andine Extension Railway Co., Ld., with a capital of £500,000; Peter Stubbs, Ld., with a capital of £150,000, to carry on the business of engineers; The Morgan's Automatic Electric Signal System Syndicate, Ld., with a capital of £5,000; The Sheffield Smelting Co., Ld., with a capital of £150,000; The Paragon Smoke Preventer, Ld., with a capital of £30,000; The Goldenhill Ironstone, Coal, and Oil Syndicate, Ld., with a capital of £1,000; The South Staffordshire Coal and Iron Syndicate, Ld., with a capital of £5,000.

Copper.—In their monthly report, Messrs. Lewis & Son state that after advancing from £50 10s. to £52 per ton for cash good merchantable copper, and from £51 to £52 10s. for three months prompt during the first week of the year, the improvement was checked by the sale of about 4,000 tons of copper by one of the French bankers to London dealers. This had the effect of placing a large number of warrants on the market, and causing the demand to be freely met. A decline ensued, until £48 12s. 6d. was accepted for cash, and £49 5s. for three months prompt on the 24th ult. On the 30th, £49 was paid for cash, and £49 15s. for three months, but the market closed at £49 2s. 6d. for cash and £49 12s. 6d. for three months prompt sellers. The fall of 10s. per ton in pig iron warrants and the dearness of money have assisted to depress the value of copper.

Shipping.—During the last fortnight freights have been dull, and not much business has been done. Shipbuilders are still busy on old contracts, but very few new orders are obtained. Prices continue to be above the value of tonnage.

Electrical Engineering.—Messrs. Woodhouse & Rawson United, Limited, have declared an interim dividend of 15 per cent. per annum, which shows a prosperous state of affairs.

The Association of Sanitary Inspectors.—The Association of Public Sanitary Inspectors of Great Britain held its seventh annual dinner on Saturday; Dr. B. W. Richardson presided. In giving the toast of "The Association and its President, Sir Edwin Chadwick," Dr. Richardson gave a sketch of the history of the society. Referring to Sir Edwin Chadwick, who had been the president of the Association since its formation, Dr. Richardson said that the record of the work he had done was written in the history of the century. Though brought up for the Bar, with great abilities in that direction, he had lent himself to new and simpler work. For a period of over sixty years he had continued to spread sanitary light in England, and had made sanitation what it never could have been if he had not lived to be its guide, philosopher, and friend.

London Geological Field Class.—A course of four lectures will be delivered by Professor H. G. Seeley, F.R.S., on February 15th, and the three following Saturday afternoons, at 4 o'clock, by permission of the Gresham Committee, at the Gresham College, Basinghall Street. The subject will be "The Tertiary Rocks on which London Stands." The price of tickets for the course will be 5s. each, and they may be had of J. Herbert Hodd, Hon. Sec., 30, Hatton Garden, E.C.

MANCHESTER, 6th February, 1890.

The Iron Trade.—The continuous fall in the price of pig iron warrants in Glasgow has practically stopped buying in this market. Makers of all brands are adhering firmly to their nominal quotations, but there is not enough business to test prices. Most consumers are covered for their present requirements, and are unwilling to do anything more until they see how the market is likely to turn. On the other hand, makers have contracts booked at the higher prices sufficient to carry them on for some time to come, and are therefore indisposed to sell at much below late rates. The result, therefore, is a deadlock, which, however, must terminate in a short time. Bar iron is decidedly easier in tone, and there is a little underselling by merchants for prompt deliveries. Steel boiler plates remain firm, and do not seem to be much affected by the movements in pig iron. The price of fuel is now a serious factor in local ironworks, and it appears as if a further advance would be obtained by the colliers, who have agreed to send in notices to cease work on the 10th of this month unless 10 per cent. advance is granted.

The Engineering Trades.—The condition of trade amongst engineers is good, and in all departments there is no falling off in the activity prevailing. Prices have not yet been raised in accordance with the increases in raw materials, but they are higher than they were. Boiler makers possibly form an exception to the rule, as raw material is such an important item in their manufacture that it is absolutely necessary to obtain enhanced rates. Millwright work is being cheaply sold considering the present conditions of things. Machine tool and locomotive builders are fully occupied and have a lot of business booked. Machine makers are working at the highest pressure and orders are coming freely from India, America, and the Continent. There is also a steady flow of business from the home market, and generally prospects are very bright. Loom makers are fairly employed, but are not yet increasing their business. Messrs. Wm. Smith & Sons, of Heywood, are engaged in the erection of a carpet loom which is intended to weave carpets 12ft. wide, further details of which we will give at a later stage.

The Linen and Jute Trades.—Business amongst the large distributing houses here has been interfered with considerably owing to the fact that retailers are too busy with their annual sales to attend to travellers. This has made the results of recent journeys very poor, although samples of new styles had been prepared for the purpose of showing. These disappointments, however, are only temporary. Scotch coarse linens are in moderate request at unchanged prices, and Leeds continues to do a fair business in crashes and other specialties of the town. Leeds crashes are noted for their quality, and are much dearer than the general run of these goods. The carpet syndicate has not yet been definitely arranged, and those jute and linen manufacturers doing business with carpet producers are still without positive information. In the meantime, the carpet trade is greatly depressed in consequence of the general uncertainty prevalent. The fancy linen and fancy jute trades are brisk, and looms are well engaged. Handkerchiefs are in active demand, and stocks are low. Prospects of trade in these articles are as satisfactory as ever, and makers must be making considerable profits. Linen threads are without appreciable change.

Hydraulic Power.—The Manchester Town Council has determined to authorise the Waterworks Committee to oppose the Bill—of which we gave some particulars recently—promoting a scheme of high pressure hydraulic supply. It was stated that £6,000 per year was paid to the Corporation for water supplied at ordinary pressure for small motors, and that when the Thirlmere scheme was complete a pressure of from 220lb. to 240lb. would be obtained.

Board of Conciliation.—It is proposed to form a Board of Conciliation from the directors of the Manchester Chamber of Commerce, who shall adjudicate upon labour disputes in this district. The directors are willing to consider the proposal if the consent of the employers' associations and the trade unions in the district can be obtained, and a scheme formulated by which each would be bound.

Short-reeled Cotton Hanks.—At the last meeting of the Manchester Chamber of Commerce, Mr. Hahlo called attention to a practice which he alleged existed of short-reeling yarns sent from Bombay to Calcutta. He stated that English yarns sent to the latter place were bound to be full length and correct counts, while yarns sent from Bombay were short length and coarser counts than marked. It was pointed out that no supervision was exercised over yarns sent out of either this country or India, but only those imported, nor was it possible to exercise such a supervision over internally shipped goods, which could be refused by the buyer if not up to standard.

Weavers' Grievances.—In a report issued by the secretary of the Preston Power Loom Weavers' Association attention is called to an alleged system of driving by which the weavers are pressed beyond a reasonable limit. It is asserted that many accidents occur by reason of this practice, and that a deleterious effect is produced on the health of the workpeople. It is proposed to take active steps to stop the practice.

Chemical Trade Amalgamation.—The well-known works of Messrs. I. Levinstein & Co., one of the leading English aniline manufactories, has passed into the hands of the Actiengesell-chaft für Anilin Fabrikation of Berlin. At the same time the works of Friedrich Bayer & Co., of Elberfeld, have become the property of the new concern, which in England will be carried on as I. Levinstein & Co., Limited, Mr. Levinstein being managing director. A considerable enlargement of the Manchester works is to take place, and the amalgamated concern will be a very strong one.

GLASGOW, 6th February, 1890.

Pig Iron.—The selling in this pig iron market has been more and more pronounced every day this week. No amount of buying seemed to stop the fall, for the impression was spreading among holders that the lull in shipbuilding, and the falling off in the shipping demand, necessitated a return to a lower platform of prices all round. A few "bears" went as far as to indicate 55s. as a figure likely to be reached ere long; but few anticipated that we would be as low as 52s. so soon. As usual, selling brought on selling; no fresh set of buyers was found willing to take the place of those who wanted to get out. Quite possibly 52s. for Scotch, 63s. for hematite, may at last attract investors who have kept aloof all the time that we were at fancy prices.

Shipbuilding.—A decided calm has supervened in shipbuilding. Some four vessels only have been ordered on the Clyde during the past ten days. Yet this falling off has not yet diminished the briskness at the yards. Indeed the want of orders is to some extent due to the uncertainty of delivery, although no doubt the fall of freights, and the relatively high prices of labour and material, are mainly to blame for it. The vessels laid down at the beginning of the revival are now coming into the freight market, and the increased tonnage is beginning to tell.—Mr. Carmichael, yard manager for the Fairfield Shipbuilding Company, leaves that firm almost immediately for the yard of Messrs. Caird & Co., Greenock. He will be succeeded by Mr. Robert Middleton, who has been at the head of the drawing office for some years. The "Normannia" will be launched by the Fairfield Company on Saturday, the 1st prox.—At a dinner given by the directors of the Fairfield Shipbuilding and Engineering Company to the staff of the works, Mr. Barnwell, chief director, who occupied the chair, mentioned that the firm had commenced the year with work in hand to the extent of 41,000 tons of shipping and 65,000 horse-power in marine engines. He mentioned also that the amount to be paid in instalments on this work, as far as executed during the year, would exceed £1,250,000 sterling. Last year the total tonnage launched b the firm had been 40,115 tons, and the horse-power produced had been 56,995. These figures exceeded those of even the year of greatest briskness in shipbuilding, the year 1883, and were far above all other years in the history of the firm.—Mr. Biles, who has been for some years at Clydebank, as scientific adviser, &c., to Messrs. J. & G. Thomson, is about to take the general management of the new firm which has taken over the business of Messrs. Oswald, Mordaunt, & Co. The new firm, which will be styled the Southampton Naval Works Company, Limited, will begin work at once. Its range will include mercantile steamers as well as men-of-war.

Scotch Railways.—In the forthcoming session of Parliament there will be fought a great Scotch railway battle. The Caledonian Railway Company are much aggrieved at the proposed amalgamation of the North British and Glasgow and South-Western Railways, and are about to promote a Bill authorising them to share the spoil of the South-Western with the North British, or alternatively to take the South-Western over on its own account. Meetings have been held in several of the towns interested, and since the Caledonian almost everywhere competes with the South Western, and nowhere has interests identical with it, expressions of public opinion are altogether in favour of the North British scheme, since competition would thereby be maintained and monopoly prevented. If the scheme be carried out as originally intended, the North British will obtain access to the coast on both sides of the Clyde, and will thus be able to compete with the Caledonian on even more favourable terms than hitherto. The details of the arrangement by which the North British proposes to take over the South-Western have now been settled. The capitals of the two companies, inclusive of debentures and loans, are put down at about £44,000,000 and £15,000,000 respectively, while the City Union Railway, which is also involved in the proposed transfer, is put down at £800,000. The arrangement involves that the shareholders of the Glasgow and South Western Railway should, after the amalgamation, become shareholders in the North British Railway. Ordinary shareholders of the Glasgow and South Western Railway are to receive from the new company a 4 per cent. preferential dividend, with a lien upon the present property of their original company. The deferred stock of the South-Western is to be converted into North British ordinary on terms to be hereafter agreed upon. It is reported that the Midland Company are pledged to support the North British proposal.

(From our own Correspondents.)

LIVERPOOL, 5th February, 1890.

The Timber Trade.—The timber trade of the past year has been, as far as volume of business done is concerned, fairly successful; the imports in the aggregate show an increase of 37 per cent. on the previous year, the consumption an increase of 15 per cent., and the stock on hand is more than double that of the previous year. Although the trade has been large, the profits, unfortunately, have not been in the same proportion. This is due to a certain extent to the

Digitized by Google

increased employment of steamers bringing forward the goods with greater rapidity than before, thus taxing to the utmost the local resources for discharging. Stocks require now to be less in consequence, and this, in conjunction with the increased freights, causes buyers to be exceedingly cautious in contracting for the coming season. This new development of the trade will ultimately require special provisions to be made to work it; and if it had not been for the action of the Timber Trade Association, obtaining the assistance of the Dock Board and the railway companies, serious strikes would undoubtedly have taken place among the men. In addition to the large deliveries on crowded quays, timber merchants complain that the shipowners claim to the last farthing whatever demurrages there may be legally due, and exact the fulfilment of the smallest conditions in their favour. The prospects of the present year are much brighter than the present state of things would appear to warrant: the volume of trade increases, and the improvement is likely to be permanent, as it is not the result of speculative operations, but emanates from a legitimate source.

THE LIVE STOCK AND DEAD MEAT TRADE.—Ten steamers arrived in Liverpool last week from the American and Canadian ports, with 2,442 cattle and 9,175 quarters of beef, showing a decrease of 440 cattle and 4,657 quarters of beef compared with the imports of the previous week.

SHEFFIELD, 5TH FEBRUARY, 1890.

THE COAL TRADE.—There is a less demand for coal than is usual at this time of the year, mainly owing to the warm weather. The official announcement of the demand from the miners of an additional 10 per cent. is causing an uneasy feeling in some branches of trade. After the last advance in January it was not expected that any further disturbance of prices would occur for at least six months. There is every intimation of a firm resistance to the proposal from South Yorkshire and East Derbyshire colliery owners. Coke of all kinds continues in brisk demand. For steel melting purposes local makers are now able to produce a very satisfactory quality. Messrs. Crookes, Roberts, & Co., of Sheffield, are introducing a new smoke-consuming apparatus, which has at present a very promising prospect.

THE IRON TRADE.—Although rather a quieter tone has prevailed for the past week or so, there is at present no diminution in the demand for iron of all classes. One of the best indications of this is to be noticed in the fact that Messrs. John Brown & Co., Atlas Works, have re-started another blast furnace. The demand for railway material still continues good. Tyres are quoted at £11 per ton; axles, best charcoal iron, £10 to £12 per ton; steel rails, £7 to £7 5s. per ton. On the West Coast some good lines are in hand by Messrs. Cammell for colonial and foreign railways. The Rolling Mills Association has again raised the prices, varying in amount from 5s. to 10s. per ton. Steel of all classes is in good demand. Castings of crucible and Siemens steel continue to be made in large quantities.

NORTH STAFFORDSHIRE, 5TH FEBRUARY, 1890.

THE IRON TRADE.—The depression in the Scotch and North of England iron trade, believed to be mainly due to speculative influences, is adversely affecting prices and demand in this district. Consumers and merchants are waiting to see the outcome of the struggle between the "bulls" and the "bears" in the North, and the feeling of confidence in the future of the trade is being lost. There is a general belief, however, amongst producers that as the year advances there will be a further improvement in prices. At the present time Middlesbrough iron is being imported into this district at prices below those ruling for local brands of pig iron.

THE COAL TRADE.—The extreme mildness of the season has effectually dispelled the hope entertained by some colliery proprietors of seeing coal selling at £1 per ton at the pit, which there is little doubt would have been the case had the weather been less propitious. Prices are lower, and the demand is not equal to the supply.

IRONWORKERS' WAGES.—In accordance with the terms of the sliding scale the prices taken out for the past two months gives the ironworkers an advance of 5 per cent. in wages.

LEICESTER, 5TH FEBRUARY, 1890.

WOOL SPINNING AND YARN TRADES.—The wool market shows but little variation since last report. Holders of stocks are not pressing sales, and consumers appear to have faith in the maintenance of current rates. There is a good consumption, and the tone of the market is very confident. This feeling has been largely stimulated by the results of the Colonial wool sales. Choice wools are not quite so plentiful, but skin wools are in good demand and find a ready sale.

HOSIERY TRADE.—Business is not very good or very bad in this industry. A fair amount of trade is being done, but the weather has considerably interfered with the selling of the kinds usual at this period. Most of the houses are busy with sampling for the spring trade, and a few orders have been placed. Though the output is not so large as is desirable, the prospects for the coming season are on all hands deemed satisfactory.

BOOT AND SHOE TRADE.—An excellent trade is being done. Most of the houses are working up to their full capacity, and some are working overtime. The amount of business is without parallel at this time of the year. A very cheerful feature of the present briskness is that orders for large amounts are still coming in freely, so that there is every prospect of a good trade for some time to come. The leather merchants are doing a good business both in present sales and contract orders. Prices are firm at late rates, with a slight tendency to harden in some lines.

SWANSEA, 5TH FEBRUARY, 1890.

TINPLATES.—The continued advances in the price of bars, without a corresponding rise in the selling price of plates, is becoming a matter of such serious import to the trade that it is compelling concerted action between the masters and the men. A meeting of makers and their employés was held last Thursday, when it was agreed that all tinplate works shall be closed in March for two weeks, and a like stoppage be repeated at intervals, if found necessary, so as to reduce the output. The total exports of tinplates in 1889 amounted to 437,800 tons, or an increase of 46,000 tons on the previous year, so there appears to be every justification for the hope that a bold and determined front on the part of the manufacturing interests may quickly change the "bearing" tactics of the merchants, and thus make the proposed stoppage unnecessary.

LOCAL RAILWAYS.—Subject to the approval of Parliament and that of the shareholders, an agreement for amalgamation has been decided upon between the Great Western Railway and the Whitland and Cardigan Line, by which the former company take over the latter railway. Mr. W. H. Mathias has secured the contract for the construction of the Cowbridge and Aberthaw Railway, the first sod of which is to be cut on the 7th inst. The directors of the Taff Vale Railway recommend a dividend of 10 per cent. on the ordinary stock for the half-year ending 31st December last, carrying forward a balance of £579. It is stated that this railway has carried 125,000 tons of coal more in that time than during any previous similar period. The Rhondda and Swansea Bay Railway are seeking powers to authorise the company to construct additional short lines as well as a wharf, and to raise £66,000 in shares and borrow £22,000 for the purpose. The falling off of 26 per cent. in the exports from Newport is mainly attributed to the various reductions which have been made in the carriage of Monmouthshire coal to Cardiff, the Great Western Railway having by successive steps lowered the former rate of 1s. 6d. to the present charge of 10½d. per ton. No corresponding reduction has been made in the rate for bringing coal from the Rhondda Valley to Newport.

THE LANDORE ALKALI WORKS.—Mr. Kirkman notifies to the local press that the increase recently demanded by the men was for piece work, and ranged from 22 to 28 per cent. for loading and discharging, although already paid at such high rates as to enable them to earn 6s. per turn of nine or ten hours for work that is considered to be well paid at 3s. per day in other places.

BARROW-IN-FURNESS, 5TH FEBRUARY, 1890.

IRON.—Hematite iron remains in brisk and steady consumption, but the actual business with makers is on a small scale. This is owing to the attitude they have assumed in reference to the speculative action on the part of holders of warrants. The latter have gone down in price to the extent of 5s. 6d. per ton on the week, and are now quoted at 63s. per ton, or something like 17s. below the actual cost of production. It is evident a position like this cannot long be maintained. Makers must have relief from one quarter or another, either in the shape of cheaper raw material and a lower rate of wages or in a higher price for the manufactured article. The belief is still generally entertained that prices must advance, as it is impossible to get raw material at a cheaper rate when the iron mines and the coke ovens cannot give adequate supplies at present for the furnaces.

STEEL.—There can be no question as to the permanence of the briskness of the steel market for many months to come. Makers are steadily employed in all departments, and orders are still offering on a large scale all round. Rails are in full demand alike on home and foreign account, the Continental inquiries being numerous and important.

CHEMICAL WOOD PULP.—The new chemical wood pulp works at Barrow have been started, and the output is being increased day by day as the machinery and the digesters are put in operation. A brisk trade is offering, and the new concern starts with every prospect of a very busy trade for a long and indefinite period to come.

MIDDLESBROUGH, 5TH FEBRUARY, 1890.

PIG IRON.—The pig iron market is quite in a state of collapse. This has been caused by the reckless buyers becoming as reckless sellers, who have thrown their iron upon the market either from timidity or weakness. Makers ask 60s. per ton for No. 3 G.M.B., prompt delivery, but no one will give that price, as warrants can be had for so much lower. Cleveland warrants are quoted at from 53s. 6d. to 54s. per ton. On Monday the stock in Connal's store amounted to 184,227 tons, as against 184,016 tons on the previous Monday.

SHIPMENT OF PIG IRON.—The shipments of pig iron from the port of Middlesbrough for the month of January are most discouraging, being 40,574 tons, as against 74,725 tons for January, 1889. The main falling off has been in the shipments to Scotland and English ports. The shipments coastwise only amount to 20,068 tons, as against 46,484 tons during the same month last year, and the shipments abroad to 20,506, as against 23,931 tons. With Cleveland as dear as Scotch, this can hardly be wondered at.

IRONMASTERS' RETURNS.—The make of all kinds of pig iron during the month of January amounted to 236,337 tons, against 241,806 tons in December, showing a decrease of 5,479 tons with the same number of furnaces blowing.

NEWCASTLE, 5TH FEBRUARY, 1890.

THE IRON TRADE.—The reaction in the pig iron trade, which has reduced prices since the early part of January to the extent of from 12s. to 14s. per ton, has caused a depreciation in the value of finished iron, and quotations for both bars and plates are now considerably lower than at the opening of the year. Manufacturers in this district, however, are generally well supplied with forward orders, and the slackening of demand has consequently had no appreciable effect on the state of business at the works.

ENGINEERING.—At the Gateshead Works of the North Eastern Railway Company business is just now exceptionally active, there being several locomotive engines of the compound type in progress, besides a great quantity of other work. Messrs. Hawthorn, Leslie, & Co. have also some important orders for locomotives in course of execution at their Forth Banks Works. At the St. Peter's establishment of the same firm, there are two large steamers receiving their machinery. Messrs. Tangye, of Birmingham, are supplying through their Newcastle agency, 45 duplex pumps of the new bulkhead pattern, for cruisers and line-of-battle ships now being built for the Admiralty. They have also on order for the Palmer's Shipbuilding Iron Company, Limited, six centrifugal circulating engines for use on the three cruisers that are being constructed by that firm.

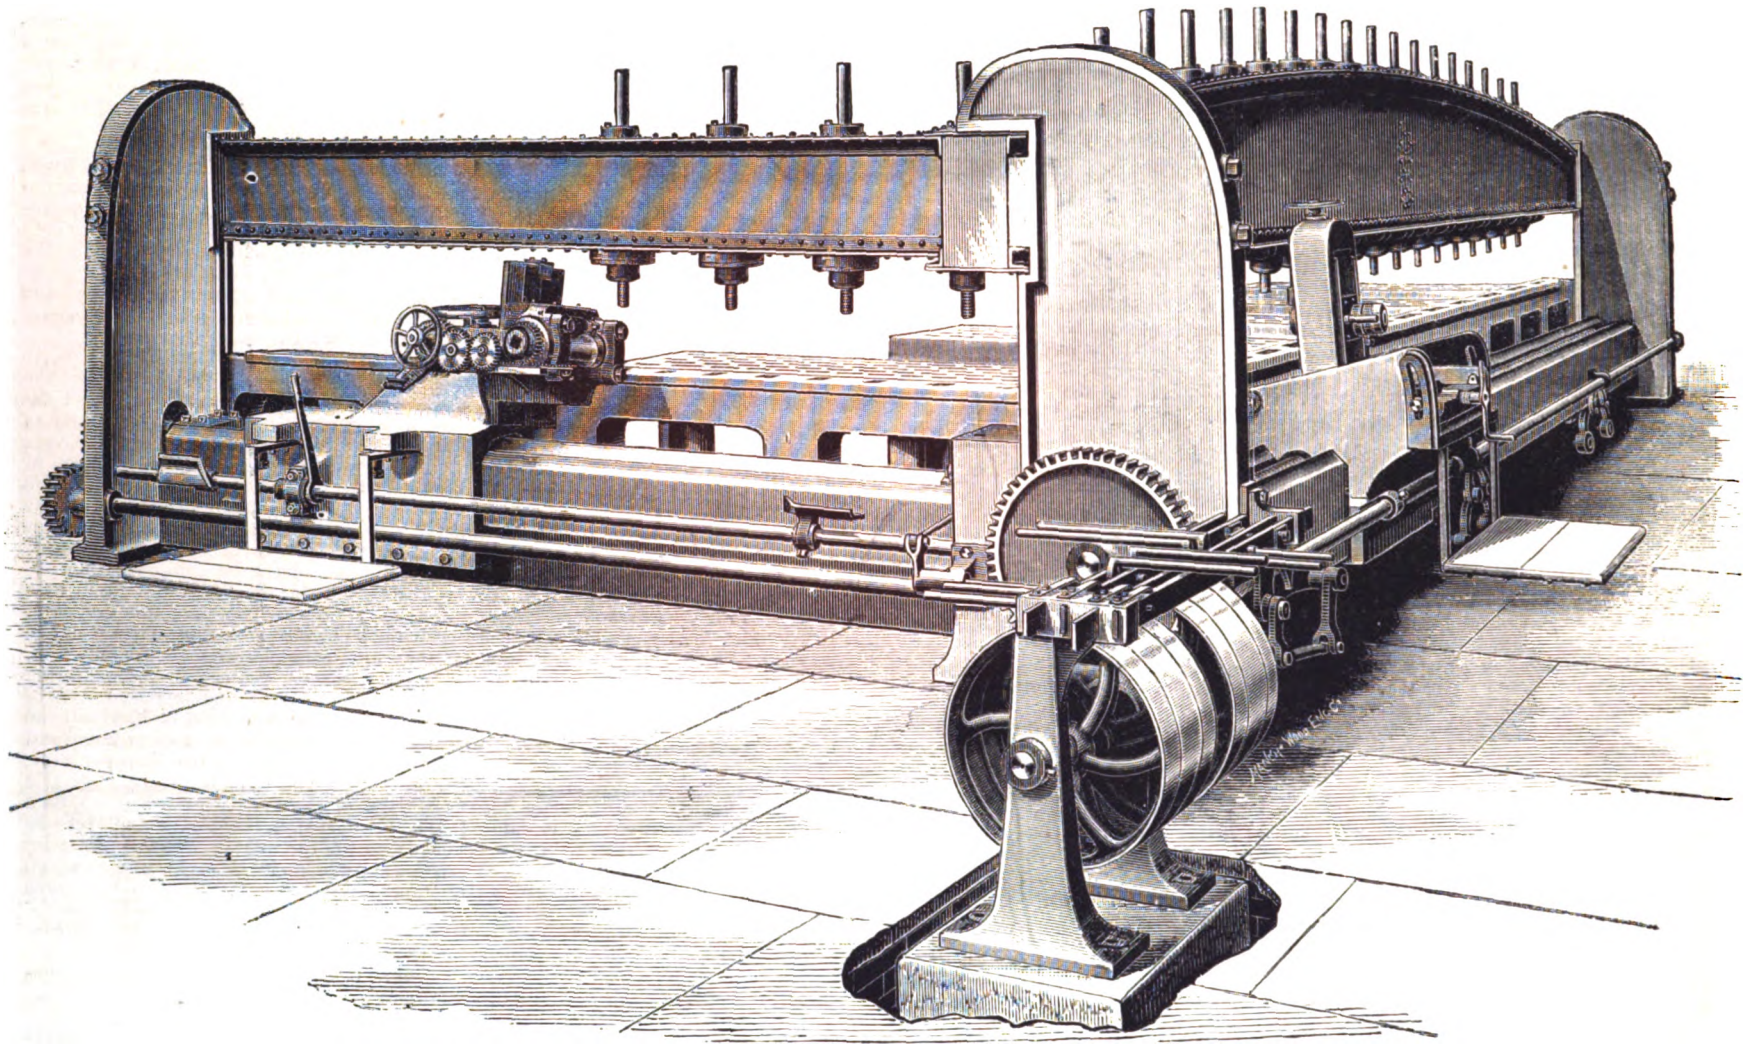
ENGINEERS' WAGES, &C.—A conference of engineering employers of the Tyne and Wear, and representatives of the workmen on both rivers, was held in Newcastle on Tuesday, to discuss the claims for an advance of wages and a reduction of the working hours by one hour per week, lately put forward by the latter. The result was to be laid before mass meetings of the operatives to be held on a later date. It is understood that, though the employers are willing to concede a part of the wages claim, they are quite determined to resist any change in the working hours which involves a reduction of the same. They have indeed taken steps to ascertain the opinion of the Iron Trades Employers' Association on the question, and that opinion is decidedly averse to any reduction of the present working hours.

THE COAL TRADE.—It has been arranged to hold a conference of coalowners and miners' representatives at Newcastle, on Saturday, the 8th inst., to discuss the demand of the Northumberland miners for a 20 per cent. advance on the wages rates. The shipments of coal and coke at Tyne Dock for the week ending February 1st amounted to 94,130 tons, being a decrease of 11,282 tons as compared with the shipments for the corresponding week last year.

ELECTRICAL ENGINEERING.—Messrs. C. A. Parsons & Co. have now got their extensive works into full operation. The works are conveniently situated near the Heaton Station of the North Eastern Railway, in a suburb of Newcastle-on Tyne, and are connected to the railway by a siding to facilitate the delivery and departure of heavy goods. In addition to other well-known specialties, the firm are now busy with the manufacture of low-speed dynamos of several types. They are also carrying out a very extensive order for the Italian Government for a number of large projectors and automatic lamps of improved design for coast defence. They have also in hand some large contracts for material for the Newcastle and District Electric Lighting Company.

BELFAST, 5TH FEBRUARY, 1890.

THE DOCK LABOURERS' STRIKE.—The strike among the dock labourers still continues, and is causing much inconvenience. Ships arriving to discharge have to be content with such small gangs of raw hands as they can pick up. The strike is seriously affecting Belfast shipowners in other ports besides Belfast where the Union has power, for when their ships arrive they are rigorously boycotted. Shipowners, however, state that they intend holding out to the last against the men, and say that in a few weeks the new hands will be quite as capable as those now on strike.



SHIPBUILDING.—All the yards continue very busy. The stocks are all full, and several vessels of large tonnage are lying in the finishing berths. Inquiries for new vessels are, however, rapidly falling off, and, as wages still have an upward tendency, it is expected that they will become still fewer. Builders are greatly handicapped at present, both from the unsteady habits of the men and from the large amount of sickness existing among them.

LINEN TRADE.—During the past week there has been a great falling off in the amount of business done. The stock of yarns remains small, and prices are firm, but the demand is very moderate. Cloth remains steady in price, and producers are mainly engaged on past contracts as sales are very small. Finished goods are not in good demand, but stocks are low and prices firm.

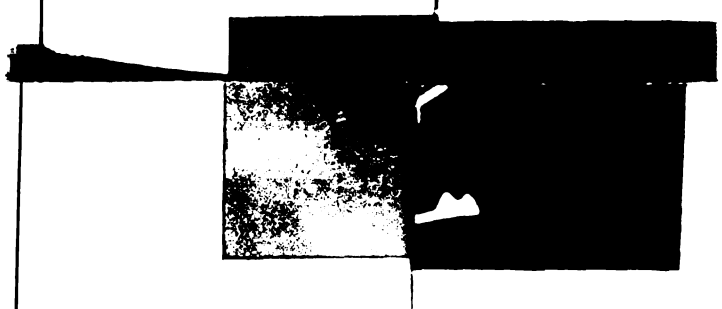
PLATE PLANING MACHINE.

CONSTRUCTED BY MESSRS. HETHERINGTON & CO., ENGINEERS, MANCHESTER.

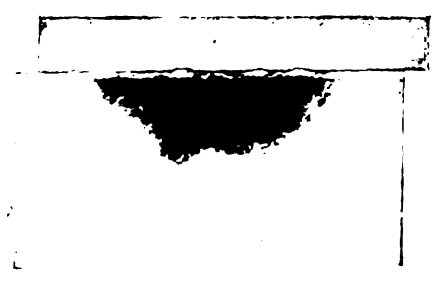
THE PROPOSED FORTH AND CLYDE CANAL.

IT is quite evident that before this canal is carried out we are to have a controversy on the merits of the different schemes, and it is well that these should be fully considered before the plans are finally decided. The Home Committee of the Glasgow Chamber of Commerce and various similar bodies have now the different schemes under their notice, and the matter is being very fully discussed in the newspapers and by various non-official bodies which are taking an interest in the subject from a scientific or a national point of view. In our last volume (pages 286 and 498) we gave a sketch of the two proposed routes; the one by Loch Lomond, which was favoured by Messrs. Stevenson, and for which they had made out approximate estimates; the other, which may be called the direct route, and which seemed to be preferred by the people of Glasgow as likely to be of most use to that city and neighbourhood. A vigorous correspondence has been kept up in favour of that route, and a preliminary committee was appointed to further its interests; the consequence is that the scheme has gained a number of enthusiastic adherents and a large amount of useful information has been collected regarding it. The committee are of opinion that the information tends to prove most conclusively that a ship canal by the direct route is practicable, not only from an engineering, but also from a commercial point of view. Mr. R. T. Moore, C.E., Glasgow, has prepared sections of the district, which show that there are about thirty or forty different seams of coal, besides other valuable minerals, extending along the whole district of the proposed route. From the report of the Royal Commission on Coal (1868–71), it appears that the Edinburgh, Fifeshire, and Frith of Forth coalfields contain more than the half of the coal in the whole of Scotland. There is no proper outlet for this great coalfield at present. The committee are of opinion that the revenue derived from this source alone would be sufficient to yield a good return on the cost of construction, but on this point they propose to submit more complete information shortly. They believe, so far as can be ascertained without an actual survey, that the line following as nearly as possible the course of the Kelvin, Bonny, and Carron is the most suitable, as by following this route it is expected that, with an improved system of locks, the average cutting along the whole route would not exceed 40ft. in depth, and that the excavation could be done for two million pounds. Adding three millions for purchase of land, construction of bridges and locks, and contingencies, it is thought that the total expenditure would not exceed five million pounds.



According to Messrs. Stevenson's report, the Loch Lomond route will require an expenditure of eight million pounds, so that in the matter of capital required the direct route has a considerable advantage. Before the merits of the two schemes can be properly discussed, the promoters should make a clear statement of the main objects they have in view, for it is quite evident that unless these agree the two schemes are not directly comparable. The chief object of those who favour the direct route seems to be to develop the mineral resources of the district through which the canal will pass, and to advance the manufacturing interests of Glasgow; while Messrs. Stevenson maintain that the indispensable features of the proposed canal should be that it have sufficient dimensions to allow the vessels of the Navy and the largest merchant steamers to pass freely and safely, and that without the use of hydraulic hoists and locks. The one proposal is therefore largely local, while the other is national. The Messrs. Stevenson further express the opinion that the Admiralty would never consent to the ships of the Navy entering the Clyde near Glasgow Harbour, while the owners of merchant ships would also object to Clyde dues and to the dangers arising from the restricted channel. Whether a compromise can be made of all these points and of the interests involved is a subject requiring the grave consideration of the promoters of the two schemes. We would advise them to try to place their rival proposals before the public in a somewhat more logical method than they have yet attempted, first by giving a clear statement of the chief objects they have in view, and then showing how these affect the commercial aspects of the schemes.

PLATE PLANING MACHINE.



AN illustration is given above of a powerful machine which is designed to plane the edge and butt of an iron or steel plate at the same time. As shown the machine consists of a strong bed on which longitudinal and transverse slides are formed. Two tool boxes are used, each being sustained on a saddle fitting one of the slides. The necessary traverse is obtained by steel screws of large diameter and quick pitch fitting into gun-metal nuts in the saddle. When the carriages have made the required traverse—each being arranged to do so simultaneously—their direction is reversed, and at the same time the tool box is revolved, so that the tools cut during the backward as well as the forward movement. The tool boxes can also be swivelled to give any bevel to the plate edges. The driving is obtained by two open and cross belts in the manner shown. Both the top beams are made of steel, and the binding screws are strong, being arranged so that they are set down by the revolution of nuts. In this way they are not revolved, and any chance of shifting the plate is obviated. In some cases the makers fit a series of hydraulic rams instead of screws. The general design of the machine is strong, and it is very massively constructed. As shown the machine is capable of dealing with plates 27ft. 6in. long by 8ft. wide. It will be noticed that a platform is suspended from each carriage, so that the workman can accompany his work. One of these machines has been working for some time in the yard of Messrs. Harland & Wolff, Belfast, and the makers have recently completed another for a Scotch firm. Messrs. Hetherington & Co., of Manchester, are the makers.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 7TH FEBRUARY, 1890.

LEGISLATION AND INDUSTRY.

SOME three years ago we drew attention to the wave of enthusiasm for State interference with industry which was then passing over the public mind. Within a short period upwards of one hundred Bills had been brought before Parliament, not by one party alone, but by all parties, making, in more or less evident fashion, for the diminution of the range of individual freedom and the enlargement of the domain of State control. Within the past two years, however, there has been a much less definite tendency towards what may, for want of a better name, be called State Socialism. The immediate reason of this depression in the wave is not far to seek. Trade has been good during these years. The great dulness has passed away, and with it has gone also, at any rate for the time, the feeling of disquietude with economical conditions which suggests the arm of the State as the most potent to right what is obviously wrong. While workmen are idle and profits are low, labourers and capitalists alike are apt enough to avoid any strenuous study of the causes of the phenomenon of dull trade, preferring to move on to the broad shoulders of the State the responsibility of doing something to give trade a fillip. But when trade is brisk, this external pressure is absent, and statesmen, never prone to move in any direction unless urged thereto by public opinion, do not voluntarily increase their responsibilities by enlarging the area of the operations of the State. Thus we have had relief for a time from any definite wave of Stateism—to coin a term opposed to anti-Stateism, or the policy of *laisser-faire*. But in the session of Parliament about to open some old measures will be resurrected, and some new ones brought forward, whose aim will be to secure an assumed benefit for the mass of the people, and whose effects will be curtailment of individual freedom, extension of the duties of the policeman and the inspector, enlargement of the category of crime, and, may be also, defeat of the object aimed at. The Eight Hours Bill, the Steam Boilers Bill, and other measures of this order will come before Parliament next session. These few cases will not make a wave of Stateism; but they will keep the idea fresh in the public mind, they will maintain a continuity of pressure along a certain line, and will prepare the way for more drastic proposals whenever the economical situation favours their advancement. It is well to clearly recognise this, because only by basing our approval or rejection of measures of this kind upon knowledge of general tendencies can we be sure, so far as surety may be, that we are acting wisely in approving or rejecting them. With the immediate prospect before us of the discussion of at least a few proposals for the extension of the field of State influence, and with a little more remote prospect of a return of the wave of enthusiasm for these, it would be well to note some recent cases and to examine some of the general arguments for and against such legislation. Measures for the extension of State interference in affairs of industrial life, or of individual life in forms of activity otherwise than industrial, have not been promoted exclusively by any one party. During the past half century, now one party and now the other, or the third or fourth party even, has promoted measures of this kind. Sometimes, doubtless, these have been promoted out of genuine enthusiasm for public advantage, more often out of genuine party selfishness or even desire of individual self-aggrandisement. While it is true that the mediæval polity, with its pervasive system of prohibitions, indirect taxes, and privileges—class and individual—has given place to a polity comparatively free of these, it is also true that at least during the past forty-five years we have been again building up a system of protections and privileges. Some of these may be highly expedient, but their existence is unquestionable. Indeed it would take innumerable Acts of Parliament repealing others to give us even an approximation to *laisser-faire*. The curve of State interference has been a wavy curve, but it has always been far above the base line of "let alone." The Limited Liability Acts, for example, defensible as they are on many grounds—that of their fostering industrial enterprise, for instance—have the effect of granting a privilege of exemption from full responsibility for acts done in the name of shareholders in companies registered under these Acts. Association has been encouraged, but at a certain cost, both in principle and in material means. Again, the Electric Lighting Acts have undoubtedly tended to the suffocation of an industry important in other countries, and to the stultification of invention; while monopolies, whose existence they were intended to render impossible, are actually growing up under them. The Factory Acts, too, passed in a rush of humanitarian impulse, are probably to blame largely for the system of "sweating," and are certainly to blame for the large amount of work done domestically under conditions vastly inferior to those of the average factory. We may look upon such proposals altogether apart from any party bearings, and without the suspicion of class bias, since a general principle, if it be a sound one, must be used unreservedly all round.

The general, if somewhat vague, argument for all measures involving the active interference of the State, is that they will conduce to the public good; and when those who argue in this way are pressed they take refuge in the Benthamite maxim of "the greatest happiness of the greatest number." Referring to well-known criticisms of this maxim, it may suffice in the meantime to point out that, in recent times at any rate, legislation has not been characterised even by pretended obedience to the maxim, nor is it always capable of being judged by it. In legislation upon the employment of women and children in factories, for example, the ratio of these to the whole of the population is, as matter of fact, never taken into account, nor is it easy to see why it should be. The title of the State to interfere between employer and employed, and to prescribe the number of hours during which work is to be carried on, depends really upon some other consideration than the "greatest good of the greatest number," however the meaning of this always vague expression may be expanded or contracted. Given the right of the State to interfere, or granted the expediency of its doing so, the circumstances of a proportionally infinitesimal group might justify—might, indeed, on these assumptions, demand—a legislative Act. Given, on the other hand, a case in which the "good" of a certain number is opposed to the "good" of a smaller number, will the State be justified in regarding the "good" of the greater number, since the "good" of the "greatest" number—that is, the whole—cannot be secured by any action of the State? These conundrums in political ethics are, however, for those who care for such things. For the practical man, the real questions are, Ought such or

Digitized by Google

such a result to be aimed at? and, Is it likely to be better secured by State action, or by spontaneous individual action? And here we cannot usefully stray from concrete cases. Let us take the Eight Hours Bill. A diminution of labour for those who are at present overworked is a result which will generally commend itself, permanent overwork being a disadvantage both from the individual point of view and from the point of view of national productivity. On the other hand, a diminution of the hours of labour of those who are not overworked, who do not need such diminution and do not want it, would be a sheer absurdity. Can the State secure the desirable result without also securing inevitably the absurd one? The miners have been selected as the first body of workmen for whom the eight hours day is to be obtained. But do they need it most, or do they need it at all? Their Unions are strong, their action fairly unanimous. They practically just now fix their hours of labour as no other trade does. If one party to a contract gets habitually his own way in fixing the terms of it, it is a little too much to ask that the State should pass a law which should have the effect of confirming this advantage. Besides, this arbitrary fixation of the length of a day's labour may conceivably operate injuriously to the interests of the miner. At times his day may, owing to the conditions of trade, fall short of eight hours on the average over the week, and thus, on the average over a year of varied trade he might be compelled to work a much lower average of hours than he would otherwise have worked. His earnings would thus be smaller; he would be less able to resist a reduction of wages or claim an advance when it became advisable that he should do so. But the miner, as matter of fact, has shown himself tolerably apt in managing his own affairs, and the Continental miner has at last determined to imitate his English brethren, and strike, when needs must, for higher wages. Nothing is more indicative of the economical strength of the miners' position than the Continental strikes and the simultaneous advances in wages in this country. In factories where work cannot be carried on without women and children, whose hours of labour are already fixed by law, the inspector can readily enough ascertain whether the law is being kept, though even in factories evasion is frequent; but the difficulty of preventing evasion of the law in mines, where work goes on constantly by shifts, would be extreme. Thus we are justified in concluding that the Legislature would, by the passing of the Eight Hours Bill, secure for the miners nothing that they are not amply able to secure for themselves, and would moreover find immense difficulty in securing it for them, opposed as their inspectors would be by the men themselves when their interest prompted them to work longer than eight hours, and that at the very time when watchfulness would alone be necessary. Again, the class of the community whose benefit it is here attempted to secure, needs the diminution of their hours of labour much less than those who, by the operation of the Factory Acts and from other causes, are compelled to work to exhaustion in their own homes. This class no legislation can touch, and this class has the most clamant need of the benefits the Legislature would confer. The position, then, which seems at once wisest and safest is to attempt by every means which lie in our power, whether as individuals or as members of social groups, to secure by spontaneous action what the State would wish to secure, but cannot efficiently, by compulsory action. There is a true and a false *laisser-faire*: there is the false *laisser-faire*, which, while calling to the State "Hands off!" sits still and does nothing, and there is the true *laisser-faire* which objects to State action, because private action is at once more immediately efficient and more likely to be continuous and adaptive. There is the false *laisser-faire*, which has brought upon us the assumed need for industrial legislation, and there is the true *laisser-faire*, which has wisely administered our great railways, our great lines of steamships, and thousands of industrial enterprises great and small. The valuable element in Stateism is regard for the group as well as for individuals in it, and this regard must necessarily characterise efficient opposition to State methods, as well as positive action for both individual and public benefit.

THE SHIPPING INDUSTRY.

The shipping industry is one which involves the welfare of almost all the other industries in the country, and hence it is highly necessary that no precautions should be omitted to remove causes which prevent its development, and at present, so far as we at least can learn from the reports of the various shipping associations, shipowners are in good spirits, and have few serious grievances against the Government authorities or the Legislature. This may be due in part to the influence of good trade and prosperous times, for when men are making money they are not much inclined to grumble over details, but no doubt a great part of it is due to the conciliatory spirit which has recently been displayed by the Board of Trade. Sir Michael Hicks-Beach is not only a man with a clear business head, but he also possesses that very valuable quality of being able to manage men, and at the same time practically to carry out almost all his wishes. Some of his predecessors may have had greater energy and ability, but these qualities too often carry with them an autocratic disposition which raises so much resistance, even to proposals which are good, that they accomplish less useful work than is done by very commonplace persons who are gifted with the power of managing men.

At the recent annual meeting of the Clyde Steamship Owners' Association, the President enumerated the chief points which had attracted the attention of shipowners during the past year, a few of which it may be interesting to our readers to note. The most important legislative proposals were the Railway Bills and those relating to the measurement of tonnage. The former of these was opposed vigorously by the shipowners, and with success, as the first was thrown out and the other withdrawn. The Tonnage Bill was looked upon by the shipowners as a measure whose chief object was to increase the revenues of dock companies, river commissioners, and harbour trusts at their expense, and in its original shape seemed to involve very serious consequences. In its passage through Parliament, and chiefly on account of the influence the shipowners brought to bear upon it, it was practically shorn of all the clauses which were most objectionable to owners of cargo and ocean-going steamers. The President of the Clyde Shipowners' Association, however, was of opinion that some of the owners of Channel steamers have every reason to complain of the Act as it has become law. He thinks that, in principle, they cannot object to it, as it simply abolishes double deductions on account of crew and light and air spaces, but he does not think that its action should have been retrospective, and that it should apply to steamers which were actually running and had been measured under the Merchant Shipping Acts. As a consequence of the Act, all steamers in which the deduction for machinery space exceeds 50 per cent. of the gross register are being remeasured by the Board of Trade, and without the owners' consent, and causing an additional burden to the owners of several thousand pounds a year. We are afraid that it is a necessary consequence of all legislation which is intended to remove existing evils, to press heavily on some individuals, but when it is made retrospective, a reasonable time should be allowed wherein to make the changes. In the case we are considering, however, it seems to us that the remedy to the owners is either an advance in freights or a reduction of coasting dues, and as the same class of ships is affected in the same way there ought to be little difficulty in the owners making their demands effective.

The Life-saving Appliances Act is also declared to be hopelessly impracticable, and the President expressed the opinion that, as far as he can judge, if its provisions are insisted upon, there will be nothing for it but to lay up those steamers which will be principally affected. Cargo and ocean-going steamers practically escape without any serious burden, but Channel and river steamers will find it difficult, and in some cases impossible, to carry out the requirements of the Board of Trade. It must be remembered, however, that these regulations have been drawn out, not by the officials of the Board of Trade, but by a consultative committee on which shipowners are largely represented, and it is rather a curious commentary on the efficacy of the representative system for which shipowners, and builders, as well as marine engineers, have been asking for a considerable time, to find that the first attempt has resulted in regulations which are impracticable. We suppose that the cause of this is that the shipowners on the committee have only been interested in ocean-going steamers, and have not looked after the interest of the owners of coasting and Channel steamers. The remedy for this is of course to have some one on the committee who fully understands the requirements of these latter. According to a circular sent out by the Board of Trade, the regulations are to come into force on the 31st of March next, but part of them are now postponed till the 30th June.

In these days of labour troubles and disputes, and attempts at improved organisation among capitalists and workers, it was impossible for such subjects to be left out of the President's address. Before the Association was started the shipowners in Glasgow were in a very helpless condition, but then their wants were few, and they were allowed to manage their business to a large extent according to their own wills, without the interference of the Board of Trade or any other Government Department. Now, however, legislation had become so active that the requirements of each Bill had to be very carefully studied, and very often vigorous action had to be taken, and that could only be made effective through a strong association. The President alluded to the desirability of having a national association of shipowners, and he was of opinion that if the rules of the Clyde Association were somewhat modified they would be found suitable for such a national association. Some months ago a provisional committee was appointed for the purpose of endeavouring to form such an association, and that committee seems to have thought it necessary before any progress could be made, as a preliminary step, that those existing at present would agree to merge themselves in it. This was found to be impracticable, and negotiations were dropped. The President, however, thought that the time had now come for them to make another effort to form the national association by so altering their rules, and, if necessary, changing the name of their association, as to meet the requirements of all the shipowners in the country. We would suggest that the rock on which the former negotiations failed was the attempt at too much concentration. The local associations should continue, but should send representatives to the national association, so that all interests might be considered.

It may be seen that the shipowners are beginning, like other capitalists, to observe the necessity for having some means of adjusting differences with their employés; and the President of the Clyde Association emphasised this point, and stated that in all they did they were not animated by any spirit of antagonism to the workers, and he made several suggestions for overcoming some of the difficulties with which they had now to contend. We look upon these things as very significant signs of the time; and we trust they are indicative of a state of industrial Society, in the not very distant future, when all disputes will be settled in a reasonable manner, and without recourse to the cruel and barbarous methods of strikes and lock-outs.

LLOYDS' REGISTER OF SHIPPING AND THE FORMATION OF RULES.

The result attending the recent negotiations between Lloyds' Register and the associations of engineers and shipbuilders throughout this country concerned with the question of including representatives of the latter in the Society's Executive Committee, while not all that some could have wished for, is yet highly satisfactory. What has been arranged is that six representatives of shipbuilders and six of engineers, whose appointment will lie with the Institution of Naval Architects, the Institution of Engineers and Shipbuilders in Scotland, and the North-East Coast Institution of Engineers and Shipbuilders, will meet from time to time with a sub-committee of Lloyds' specially appointed for the purpose, and will revise the existing rules of the Society or formulate new ones for regulating the construction of ships and machinery.

That the shipbuilders and engineers of this country should, as a body, have a recognised voice in the legislation by which their daily work is so much regulated and influenced is perfectly fair and reasonable. This will appear all the more unquestionable to those who know from what sources the knowledge and experience upon which such legislation is based have all along been drawn. The daily practice, skill, and experience—often dearly bought—of the shipbuilder and engineer constitute the basis, if not the whole substance, of Lloyds' rules. The practice of building ships of iron was in vogue for a quarter of a century, and was fairly perfect, before Lloyds' officials began to collect facts and figures from the more skilful iron shipbuilders from which to formulate rules and regulations. The same thing is true of the transition from wood to iron for masts and yards and of the modifications in the structure of vessels as regards double bottoms, trans-

Digitized by Google

verse web frames, &c., and to some extent it is also true of the substitution of mild steel for common iron. This implied want of originality does not, of course, mean that there has been inefficiency or incompetency in any department of Lloyds'. The functions of the Society are not so much to originate as to formulate and administer laws. These functions it is eminently capable of discharging through its large staff of able technical officials. The Society, it is true, has in times past often lagged behind, and it was only through fear for its safety or jealousy of the growing influence of rival institutions that it was spurred on to keep pace with the enterprise and intelligence of shipbuilders and owners. The admission, therefore, of those who have undoubtedly done the herculean part in forming Lloyds' rules to consultation on matters affecting the improvement and development of these rules is a step from which Lloyds' Register, even more than shipbuilders, will reap advantage and additional prestige. Like many other old institutions—especially with the autocratic and far-reaching influence it now possesses—Lloyds' is conservative in character, and is apt to display a tendency rather to stereotype existing practice by rigidly adhering to fixed rules and figures than to encourage progress by appraising new departures at their proper value. The rules as now existing are not altogether satisfactory, and call for modification and improvement in the light of what has been transpiring in daily practice. The fresh accession of experience and skill, therefore, which will be brought to bear upon them by those actively engaged in their daily practice will render the work of improvement less arduous and difficult and the result more generally satisfactory.

THE LATE GUSTAV HIRN.

Within the past few months death has been busy among the founders of the dynamical theory of heat. First, Clausius, who developed it from the mathematical side, and then Joule, who established it on a sure experimental basis, were added to the majority, and in the middle of last month Gustav Hirn, who was equally distinguished in theory and experiment, passed away, at Colmar, at the age of seventy-four.

Hirn was born at Logelbach, near Colmar, in Alsace, on August 21st, 1815. His father was one of the partners in the cotton manufactory of Haussman, Jordan, & Hirn, and his education was almost entirely of a practical nature, being obtained either in the chemical laboratory or the mechanical department of the mill, supplemented by private study. These facts explain why his memoirs are in many cases difficult to follow, being often deficient in arrangement and concentration. A trained mathematician and physicist would have been able to put the results of his investigations in a more logical form, although it is very likely he might have had some of his originality drilled out of him. They also explain possibly why he got into controversy so often with others who were working in the same fields, and why he failed to duly appreciate their work. One of his latest works, entitled "La Cinetique Moderne et le Dynamisme de L'Avenir," was written in reply to some criticisms by Clausius, while many of his best papers on the action of steam in the engine were answers to those of Zeuner. In fact, he seemed almost to require a worthy opponent to bring out his energies, and he displayed, like many other self-taught men, rather too much confidence in his own work and contempt for that of others. We must confess, however, that although we have often found his papers very difficult to follow, chiefly on account of their diffusiveness, we have generally felt inclined to think that he had the best of the argument.

With all the freedom of a self-taught genius he allowed himself to roam over the whole field of literature, science, art, and music. He made himself acquainted with English, German, Italian, and Latin, which he used, not only for the purposes of science, but also in order that he might study the beauties of their literature. He had high qualities as an artist, and if he had devoted himself to that calling, he might have left a name which would have been enrolled among those of the best artists of his time. Although he entered business at an early age, he was fortunate enough to be above the necessity of devoting all his time to merely commercial or mechanical work, nor had he any inclination to do so. He was one of the few who remember that work in itself is not life, but only a means of life, and he endeavoured to make his life as complete as possible. His experiments ranged over physics, metaphysics, and engineering. His earlier work was taken up with ventilators, hydraulics, friction, and disquisitions on the celestial space, but he is best known to engineers by his investigations on the applications of thermodynamics to the steam engine. The results of these are embodied in his well-known treatise on the "Théorie Mécanique de la Chaleur," and in the large number of papers which have appeared chiefly in the "Bulletins de la Société Industrielle de Mulhouse." Even an outline of the work he did in connection with the steam engine would go beyond the limits of our space; but we may mention his experiments to verify the value of Joule's equivalent, not only on a small scale in the laboratory, but also on a large scale with steam engines, his analysis of the heat used in steam engines, the action of superheated steam and of steam jackets. His method of treatment has been largely adopted by subsequent writers. It is rather a significant fact that the best work in this department has been done by men like Hirn and Rankine, who have not been cramped by the training or ways of thought of any special school, a fact which which should be noted by our educationists.

Hirn's character was a reflex of his work. It was noble and lofty, perfectly upright and genuine. He had always a kind word for those who were worthy of it, although he did not hesitate to utter a stern one to those who deserved it.

JAPANESE TREATY REVISION.

The latest news from Japan about treaty revision is that the whole matter is likely to be adjourned *sine die*, and that the treaties which have been made with the United States, Germany, and other Powers, but which have not yet been ratified, will be allowed to remain in abeyance, so that no international complications may ensue. It is understood that the British Government was willing to agree to the Japanese proposals, and that the difficulty has now come from the Japanese people. The proposals involved the appointment of a certain number of foreign judges, and against this provision Japanese public feeling rebels. It is also said that, on the whole, the foreign merchants are not displeased at the collapse of the negotiations; at least, they prefer that to conditions which the Japanese now wish to insist upon, namely, that they should be entirely subject to native jurisdiction. As we have pointed out on previous occasions, if a little tact and common sense had prevailed when the revision question was started many years ago, the preliminary stages of the experiment might have been passed, and an arrangement suitable to both parties have now been come to. We are afraid that all hope of a joint native and foreign Court of Appeal is gone for ever, as the question has been taken up by the people, and no Government would stand which proposed to return to that arrangement. We suppose that things will drag on as they are for a few years, and then the Japanese demands will be agreed to. We trust that they will show by their conduct in the interval that they fully realise the responsibilities which their demands would involve. In the meantime, the progress of Japanese foreign trade will be very much hindered. We are not sure, however, but that on the whole it may be better for Japan. It is not good for a country to change its industrial and social conditions too rapidly, and it will be well if the Japanese now try to consolidate and improve what has already been commenced, before the country is fully opened to foreign capital and enterprise.

THE CLEVELAND INSTITUTION OF ENGINEERS.

The second meeting of the session was held on Wednesday, the 29th of January. After some preliminary business, Mr. M. R. Jefferds, C.E., London, read a most interesting paper on the Goodfellow and Cushman light weight, high capacity, tubular frame freight cars. Mr. Jefferds introduced his subject by showing that it was by no means a new one. After referring to the progress of the means of transport by canal and by rail, Mr. Jefferds started his subject of freight vehicles. He gave great credit to England as the father of railways and George Stephenson as the creator of the locomotive, but objected to the passenger car, as being merely the old stage coach, and the freight car, as being merely the heaviest type of farm waggon mounted on flanged wheels. In passenger and freight cars America had gone very much ahead of England. In America, where it experienced the competition of excellent water-ways, the railway carried freight at three-tenths of a penny per ton per mile. In England canals were being constructed to beat the railways, which charged for freight at the rate of a penny per ton per mile. In considering the two different systems of railway rolling stock—the farm waggon and the bogie—Mr. Jefferds declared the question for solution to be: Which type requires the greatest power to move it; which creates the greatest friction; which can traverse the curves more easily; which is the more elastic and easier on the track; which has the less deadweight or tare to its carrying capacity; which is the simpler and easier of repair by unskilled labour; which requires the fewest repairs; and which is the more durable? All these Mr. Jefferds addressed himself to in turn, and decided in favour of the bogie. He then introduced the Goodfellow and Cushman freight car, and described its construction from a wall diagram.

In the discussion which followed the paper almost the only objection taken was the unsuitability of the car to local traffic, from the lengths of its wheel base, but upon the whole great satisfaction was expressed with the principle and a strong desire to see some of the cars in the general traffic of the district.

Letters to the Editor.

LARGE RAILWAY TRUCKS FOR MINERAL TRAFFIC.

To the Editor of "Industries."

Sir,—Permit me to compliment you upon your very able editorial entitled "Large Railway Trucks for Mineral Traffic," published in your issue of the 24th inst.

You have struck the keynote, but you have not given credit where credit is due. Sir James Ramsden, of the Furness Railway, was the first man in England to introduce light weight, high capacity, bogie truck freight cars, and Sir James Allport the first to introduce the bogie truck passenger cars upon the Midland Railroad. Sir James Ramsden bought about a year ago two cars, one a low-sided gondola weighing 8 tons 4 cwt., which he has been using ever since, carrying loads of 30 to 35 tons, and the other a high-sided gondola, weighing 9 tons 6 cwt., to carry 30 tons of coal or 20 tons of coke.

Three men can shunt one of these cars loaded round a 4-chain radius curve. Five men are required to shunt one of the best four-wheeled waggons loaded with 10 tons. It will therefore be seen that three men can move as much paying load on a high capacity bogie truck car as fifteen men can move on the four-wheeled, rigid wheel base waggons now in use upon English railways. This will lead you to the logical explanation of why it is that upon the poorly constructed and flimsy railways of America they can move this traffic at 80 per cent. less than they do here, where the best railways in the world are to be found.

I hope you will have the courage to go carefully into the facts of the case and "call a spade a spade," for if you do it will be but a short time before the veil will be lifted from the eyes of the public, and they can then see themselves as outsiders see them.

Modern rolling stock upon English railways would be the means of reducing rates 50 per cent., paying shareholders larger dividends than they now receive, and quickening every branch of industry in the United Kingdom. If the change is not made the manufacturing interest will go, where the agricultural interest has gone—to the dogs.

Yours, &c.,
M. R. Jefferds.

London, January 31st, 1890.

ELECTRICITY IN MINING ENGINEERING.

To the Editor of "Industries."

Sir,—In your year's review of mining, you lay stress upon the fact that little has been done here in the direction of adopting electricity in that direction. In the matter of developing the electric lighting industry we have been very slow, but there are various theories advanced as to the causes of this backwardness. The "old Act" has been made the scapegoat in most cases, but this reason does not apply to other branches of the profession. The list of electric tramways in Great Britain makes a pettifogging total of mileage, which it is depressing to look upon. The Bills to be brought before Parliament give promise of better things this year; but it must be remembered that it is one thing to give notice of applying for powers, and another to obtain them, and if obtained to carry them into practice. In transmission of power, either in connection with mining or otherwise, things seem to be even worse. On the Continent and in the United States a great deal has been done in this direction, but from some unexplained cause the progress at home is exceedingly small. The two reasons from which to select for this are either that electrical engineers have not devoted much attention to putting the merits of such systems before colliery and mine owners, or that the latter have prejudices which it is difficult to overcome. If the cause be the first I have mentioned, this speaks little for the business enterprise of our electricians; but if it be the latter, there should be little difficulty in demonstrating the advantages which can be obtained.

Yours, &c.,
M. E.

Stratford, E., 31st January, 1890.

THE DURATION OF OUR COAL SUPPLY.

To the Editor of "Industries."

Sir,—"Who shall decide when doctors disagree?" The only conclusion to come to after comparing the estimates of the duration of our coal supply made by Professor Jevons (whose ideas as to their limit seem to have been hopelessly wrong), by the Royal Commission, by Mr. Hall, and by Professor Edward Hull (a paper by whom was read in this city but a few days ago), is that it is impossible to form any sound notion on the subject at all. Professor Jevons gave us till 1960 or thereabouts; the Royal Commission allowed us to select for ourselves among 360 years, 276 years, and 1,200 years; Mr. Hall gives 200 years; and Professor Hull a choice of 880 years or 417 years, but he prefers the latter. The matter is not a pressing one, and there is something distinctly humorous in the variations of the different prophets.

Digitized by Google

What is of more practical importance is whether an effect will be produced upon prices, and on this point Professor Hull delivered himself to the Edinburgh Geological Society in the paper to which I have just referred. He came to the conclusion that failure of our coal supply to any appreciable extent in the near future is not to be expected, but that there will be a tendency towards a rise in the price of coal. This rise would be due, not to any appreciable diminution in the available quantity of coal, but to the increase of expense (including an advance in miners' wages) in mining, consequent on the greater depth at which coal must be worked as time goes on. Such increased expenses must, he said, of course be defrayed by the consumer, and he looked upon it as certain that within the next half century there would occur a general rise in the price of coal throughout the British Islands.

A strong recommendation was made by the author to adopt economy in the use of coal, and this, I believe, as stated in your leading article, will be largely brought about by the development of science in the branches of engineering, electricity, and chemistry.

Yours, &c.,
BLACK DIAMOND.

Edinburgh, 29th January, 1890.

STEAM BOILER LEGISLATION.

TO THE EDITOR OF "INDUSTRIES."

SIR,—The letter in your issue of the 24th ult., signed "Boiler Inspector" (?), entirely loses its importance so far as the paragraph relating to this company is concerned, from the source of its inspiration being so apparent. It is, therefore, unnecessary to notice the obvious inaccuracies it contains, further than to say that in all the circumstances the taste displayed is questionable.

My object in troubling you at all is to refer to the attack made upon the qualifications and abilities of our district inspector at Newcastle. This "Boiler Inspector" might have well spared a little more charity to a brother in trade, whatever he may have seen fit to write about a rival boiler insurance company. He says, "When the boiler inspector turns out to have been originally a jobbing blacksmith, the owner will have to be thankful for small mercies in regard to advice and inspection."

William Winship is too well-known on Tyneside to require any recommendation there, and far too modest to take any notice of this attempt to injure his reputation, but I feel I should not allow such a statement to pass. Mr. Winship joined this company after having had over twenty years' experience as a boiler inspector in the service of the Midland Boiler Insurance Company, under the care of Mr. E. B. Marten, whose title to speak on the question no one, I think, will dispute, and who wrote of him when he joined this company, as . . . . "a thoroughly reliable inspector of great experience."

The unfortunate circumstance in this case, so far as Mr. Winship is concerned, is that he had no opportunity afforded him of making a thorough examination of the boiler, and there is no doubt whatever that had he got such an opportunity the defective condition of the firebox would have been discovered.

Yours, &c.,
JNO. D. YOUNG, Managing Director,
The Scottish Boiler Insurance and Engine Inspection Company, Limited.

13, Dundas Street, Glasgow,
3rd February, 1890.

COMMUNICATION BETWEEN ENGLAND AND FRANCE.

TO THE EDITOR OF "INDUSTRIES."

SIR,—I have read the letter of Mr. Eug. Obach on this subject, and, without entering into any criticism of the scheme of Messrs. T. Obach and Lebret for crossing the Channel, I merely desire to state that the project to which I referred is not the same, but one of later date. The main features as given by me are, I am confident, quite correct, and it is quite possible that the proposal which I described was based by some one else upon the earlier one mentioned by Mr. Obach.

Yours, &c.,
T. C.

London, 4th February, 1889.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the tenth ordinary meeting of the Session, on Tuesday, the 4th inst., the President, Sir John Coode, K.C.M.G., being in the chair, the paper read was on "Bars at the Mouths of Tidal Estuaries," by Mr. William Henry Wheeler, M.Inst.C.E. The paper referred to the different kinds of bars, treated of causes of their formation, and suggested remedies for their removal. Four classes of bars were described, namely—those consisting of hard material not affected by the scour of the current; those due to deposit of alluvial matter brought down by rivers; bars consisting of shingle or sand; and casual bars. Examples of each kind were given. With reference to those of the second class, a distinction was drawn between bars and deltas. The latter consisted of a continually increasing deposit of fresh material, due to alluvial matter brought down by the river currents. The former were caused by the heaping up of sand or shingle by the action of littoral currents, aided by waves and gales. Tidal bars, unlike deltas, did not increase in size after formation; the balance of forces between the conflicting currents kept them in equilibrium, and caused them to maintain their general form and position. The features of bars at the mouth of sandy estuaries were described as being of a remarkable character. Such bars consisted of one or more ridges of material, the particles of which had no coherence, yet stood with a slope much steeper than the natural angle of repose. Rising in some cases as much as from 40ft. to 50ft. above the bottom, they maintained their positions across channels having a tidal rise of from 20ft. to 30ft., with a current exceeding from 3 to 4 knots, and the direction of which was reversed three times every day; exposed to the storms and waves of the open sea, they were sometimes partly dispersed, or added to, or altered their form, but they had a normal condition to which they reverted when the disturbing causes ceased. Examples were given of the bar of the Mersey and other estuaries. The author pointed out that bars were not common to all rivers, and even where a bar existed it was not always an impediment to navigation, as the water in the channel inside the bar was frequently as shoal as on the bar. The Thames, the Humber, the Severn, the Seine, and the Scheldt were given as instances of rivers without bars; the Tyne, the Tees, and the Ribble, as illustrations of rivers where the bars did not affect the navigation. The various theories as to the cause of bars were enumerated. These were divided into two classes—one class ascribing the bar to the action of the river-currents, and the other to the action of the sea. The theories of their formation might be thus summarised:—(1). The deposition of the detritus carried in suspension in a river when it entered the sea, either from the slackening of the velocity, or from the meeting of two currents which neutralised each other, or from the effect of the conflict between the salt and the fresh water. (2.) To the form and direction in which the ebb- and flood-currents met at the outfall. (3.) To an insufficiency of back-water. (4.) To the difference in duration of the ebb- and flood-currents, and the variation in the inclination of the slope of the low-water line. (5.) To the action of littoral currents, and waves driven along the shore in piling up detritus in the direction of their greatest force, and across the mouth of the outfall. With regard to the first class of theories, the author pointed out that the alluvial matter brought down by a river was of a totally different character to that of which bars consisted, being sufficiently light to be carried out to sea in suspension; that the meeting of the fresh and tidal waters, or the conflict between the salt and fresh water, could not be the cause of a deposit sufficient to make a bar, as the point of conflict varied with every tide; that fresh water floods, from their intermittent character and small volume as compared to that of the tidal water, could have little effect on the bar or outfall channel. Attention was drawn to the fact that those rivers having the largest discharge of upland water and absence of tidal flow were most encumbered at their outfalls; that, while freshets had little or no effect in scouring away bars, they not unfrequently were instrumental, in sandy estuaries, in feeding and maintaining them by altering the low-water channels through the sand, and stirring it up and throwing the sand into the ebb current, which was thus transported to the bar. The manner in which a channel entered the sea was admitted to have a marked effect on the maintenance of the bars, which were generally found at the mouths of estuaries discharging into shallow bays, or where the outfall was at right-angles to a low flat sandy coast; whereas rivers discharging at the head of a deep bight gradually increasing seawards, or discharging at a projection of the coast-line, where the run of the tide was strong, had free outfalls. The characteristics of the principal estuaries of this country were given in illustration. As to the insufficiency of back-water, the author, while admitting the importance of conserving tidal estuaries as scouring-basins, and that a certain width of foreshore on each side of the channel was essential for properly filling and feeding them, contended that only such portion of the water entering an estuary as passed in and out by means of the navigable channel over the bar was beneficial; and that the enclosure of indents and irregular parts of the coast line, by bringing the estuary into the best form for the ingress and egress of the effective portion of the tidal water, might be of advantage; that while training walls were conducive to accretion, yet they did not necessarily decrease the tidal capacity. Training walls did not create new material, but merely led to a new disposition of the sand, the shoaling in one place being compensated by the deepening at the part from whence the sand was moved; also the deepening of the channel by the scour between the walls more than compensated for loss of shallow water over a wider area. No fixed rule could be laid down either as to the best height of the walls, or how far reclamation might be carried; each estuary must be judged and dealt with as experience taught. Several cases were quoted, showing where reclamation had been detrimental, and also where it had been carried on without injury to the bar or navigable channel. The relative scouring effect of the ebb-and the flood-tide was discussed, the opinion of the author being that these were nearly balanced, the preponderance being in favour of the ebb. As to the theories that ascribed the existence of bars to external causes while generally agreeing that this was caused by the action of the sea, varied as to the way in which it was accomplished, this action was variously ascribed:— To ground waves, which, having traversed the shore, carried with them sand and shingle into the mouth of the estuary, and formed a bank; to the action of the winds, which caused the detritus disturbed by waves to be piled up in the direction of their greatest force; to the action of on-shore waves, the crests of which, being impelled forward at a greater rate than the foot by their impetus in descending, pushed forward the mass of water in front of it, which, charged with the material on which it was driven, carried it into the mouth of the estuary; to the general tendency on all coasts of waves driven along the shore by winds, or of the littoral currents, to transport and heap up beach in a continuous line along the shore, to which operation the mouth of the estuary formed no exception. The author considered the last as the true cause. The action of gales in eroding the cliffs and breaking up the beach furnished the material which was continually being transported along the beach in the direction of the flood tide, and those on-shore winds, which, from their prevalence, had the most effect on the coast. This material was carried across the mouth of the estuary, rolled along the bottom by the flood-tide to the bank forming the bar, pushed over it, and deposited on the inner side. The ebb-tide rolled it back, and it was dispersed on again reaching the sea. The bar was thus maintained in a general state of equilibrium; if in an exposed position, increasing after gales and decreasing in calms. The conditions of estuaries favourable to the formation or absence of bars were described and illustrated by reference to the various rivers of this country. The remedy proposed for the dispersal of bars was to increase the depth of water at the outfall and the power of the ebb current. The works carried out in the Tyne, the Tees, and the Liffey were described and given as illustrations of the successful application of this remedy. It was pointed out that piers run out from the shore on a flat sandy coast were not effective unless carried to deep water, and instances were given of failure where this had been attempted. Under certain conditions, a single pier, concave in form, running out from the coast on the side of the channel from which the drift came, having its concave side towards the channel, might be effective in deepening a channel and removing a bar. The author also suggested that bars might be dispersed by eroding, or stirring up the material of which they were composed by mechanical agency, and thus taking advantage of the transporting power of the ebb current for their removal.

The views of the author were thus summarised:—(1.) That the forces which operated in maintaining the existence of bars in tidal estuaries came from the sea, and were not due to upland water. (2.) That the dispersal of bars and the improvement of the outfall channels of estuaries could be accomplished by increasing the volume and velocity of the tidal water passing over the bar, and by giving a greater preponderance to the ebb current. (3.) That in designing works for this purpose, the circumstances of those estuaries which had natural deep-water channels free from bars should be taken as guides. The lessons to be taught by an examination of estuaries having natural deep-water channels were: (*a*.) That the mouth of the outfall should be capacious enough to allow of the entry of sufficient tidal water to fill up the estuary and upper reaches of the river. (*b*.) That, to ensure a regular and undisturbed flow, the form of the estuary should be such as to afford a gradually decreasing width from the outfall. (*c*.) That the depth of water in the channel should be sufficient to allow of a free propagation of the tidal wave. (*d*.) That the longer the run of tidal water that could be given the more effective would be the scouring action, and that, therefore, all obstructions to the free flow of the tidal current were prejudicial to the outfall. (*e*.) That it was essential to secure adequate depth of the channel by natural scour, or by dredging. (*f*.) That training and fixing in one position the low-water channel in a sandy estuary was of first importance in securing the full advantage of the tidal scour, and in maintaining a deep channel. (*g*.) That water, flowing in and out of an estuary which did not pass to or from the sea over the bar, and by the main navigable channel, was of no advantage to the outfall, and was better excluded. Therefore, while it was of the utmost importance to conserve an estuary as a receptacle for the tidal water, the exclusion of such water from indents, and the cutting off of irregularities by embankments, might be carried out without detriment to the outfall. (4.) That piers carried out from the shore were useless, unless extended to deep water. That they should be so designed as, while not unduly throttling the inflow of the tidal water, they should effect the greatest amount of scouring force from the ebb current.

Books Received.

Thermodynamics, Heat Motors, and Refrigerating Machines. By DE VOLSON WOOD, C.E., M.A. New York: John Wiley & Son.

The Steam Engine and Indicator. By WM. BARNET LE VAN. Philadelphia: Hy. Carey, Baird, & Co. London: E. & F. N. Spon.

Spon's Engineer's and Contractor's Diary and Reference Book, 1890. London: E. & F. N. Spon.

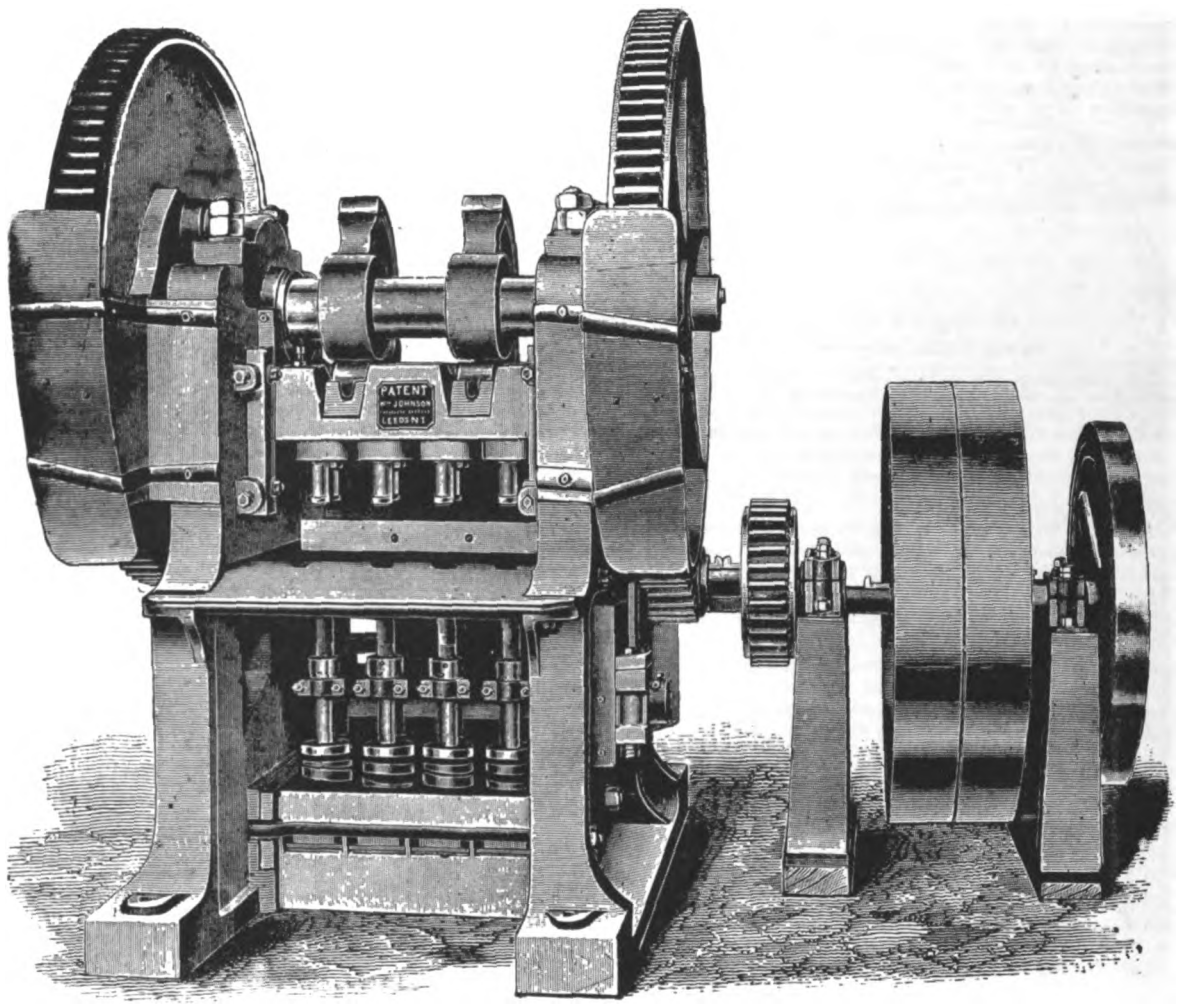
HYDRAULIC MOTORS: TURBINES AND PRESSURE ENGINES. By G. R. Bodmer, A.M.Inst.C.E. London: WHITTAKER & Co.

The present work belongs to the "Specialists Series" of Messrs. Whittaker & Co. and George Bell & Sons, but exceeds any of its predecessors in size, as it contains over 500 pages of letterpress and 179 illustrations. That so large a work on hydraulic motors should be published in the English language might perhaps cause surprise, for Great Britain is not a nation directly interested to

Digitized by Google

any extent in the utilisation of water power, and there are only very few engineering firms who make the construction of turbines a specialty. On the other hand, Canada, India, and other British colonies offer a large field for the application of these machines, to say nothing of the United States, where the use of water power is a very important element of industrial development. Thus the book will interest a large circle of readers, and should even prove useful to English engineers desirous of supplying hydraulic motors for abroad. From the general style in which the subject is treated we conclude that the author is a pupil of Zeuner, but he has extended the theory which Zeuner gave when he occupied the chair of Applied Mechanics at the Polytechnic School in Zürich, and has paid special attention to the development which had since then taken place in America.



The book begins with an introductory chapter, in which an attempt is made to classify water-power engines into three types. This classification is made according to the way in which the water acts, and comprises the performance of work by kinetic energy, weight and pressure. Machines in which kinetic energy alone is used the author calls turbines, those in which the weight of water is used he calls water-wheels, and those in which the pressure alone is used he calls water-pressure engines. Convenient as it may be to thus classify the machines according to their mode of action the classification is not quite correct. As regards water-pressure engines the author's definition is no doubt sufficient, but the hard and fast demarcation between turbines and water-wheels has no existence in practice. There are many water-wheels in which the kinetic energy of the water as well as its weight is instrumental in producing power, and similarly there are turbines in which the water acts to some extent by pressure. The author's use of the term "potential energy" is also open to criticism. According to the usual conception, potential energy is that energy which is stored up in a body by reason of its position, and which can be obtained from it if we allow a change of position to take place. Only as long as the energy remains stored up do we call it potential, but the author applies the term to the energy whilst it is being given off in the shape of pressure multiplied by volume per unit of time. It would have been more correct to call this kind of energy the energy of pressure, in the same way as we might call the kinetic energy the energy of velocity. In the introductory chapter we also find a very clear demonstration of Borda and Carnot's law, and an elementary investigation of the action of water on curved vanes, a subject which is more fully treated in subsequent chapters. We are glad to see that the author has from the outset pointed out that centrifugal force need not be taken into account, its effect being fully accounted for in the general formulæ for the flow of water along moving channels.

Chapter II. treats of turbines in general, and here the author gives a definition of the turbine to which no exception can be taken. He defines it as a water-wheel in which motion of the water relatively to the buckets is essential to its action. The usual classification into reaction and impulse turbines, and the further subdivision of each class into radial, axial, and mixed flow turbines is adopted, and examples of each are given. In the third chapter the author enters more fully into the theory of turbines, beginning the investigation with a radial inward flow turbine with suction tube. As already remarked, the treatment is similar to that adopted by Zeuner, which itself is an amplification of Redtenbacher's theory, but it is worked out in greater detail, and there are also certain points in which the two differ. Thus the author takes the ratio of the total outflow area of the guide to the total outflow area of the wheel as a starting point for the design of turbines, and he defines the angles of vanes with reference to a radial instead of a tangential line in radial flow turbines, and with reference to a vertical instead of a horizontal plane in parallel flow turbines. Thus the author's formulæ differ from those previously given on account of the interchange of the sine and cosine of angles. The following chapter deals in detail with the various losses of energy occurring in reaction turbines, whilst in Chapter V. the design of these motors is given. In applying his theory to this purpose the author starts with the condition that the water shall enter the wheel without shock, and shall leave it without velocity parallel to that of the wheel. These two conditions, together with the third condition of continuity of flow, suffice for a first approximate determination of the various angles and areas, and when this has been done the working conditions of the motor and the different losses are determined in detail, and the design is altered so as to make the sum of all the losses a minimum. The various methods employed for the regulation of reaction turbines are discussed in Chapter VI., including the theory and application of the diffuser, by means of which the loss due to the energy carried away in the outflowing water is reduced to a minimum.

Impulse turbines, including the Poncelet wheel, are similarly treated in the following two chapters, but no mention is made of the Sagebien wheel, which also belongs to this group of turbines. The loss of energy due to imperfect filling of wheel buckets when the admission is partial is very fully treated, and well illustrated by diagrams. Chapter IX. contains a series of tables, which should prove useful for the design of turbines. To make the tables generally applicable the author has given them for three sets of conditions as regards volume of water and fall. The first column applies to cases where the quantity of water is great and the fall low, the second to medium quantities and medium falls, and the third to small quantities and high falls. The use of these tables is illustrated by a selection of numerical examples. The next chapter deals with the measurement of the quantity of flowing water, and contains a very conveniently arranged table of the coefficients to be used when making such measurements by the aid of a tumbling bay. Then follows a chapter containing descriptions of turbines and results of their tests, which will be specially useful to practical engineers because containing detail drawings of several of the more important turbines which have proved successful in actual work. There is given a table showing the best speeds of turbines as found by experiment, and a comparison of these speeds with the calculated speeds. The difference is in all cases small, causing less than 2 per cent. difference in the efficiency, from which we may infer that the author's formulæ are sufficiently reliable for all practical purposes. Perhaps the most interesting part of the book is Chapter X., which deals with American turbines. American engineers have been frequently attacked by their European rivals for the apparently unscientific way in which they design their turbines, and, considering the school in which the author has been trained, it would not have been very surprising had he shown prejudice against the American turbines. There is, however, no trace of such a feeling in his book, and the author investigates the merits and faults of the rival turbines with perfect impartiality. When discussing the Holyoke tests, which show generally a much higher efficiency than European engineers are disposed to admit, the author points out that these tests not only bear internal evidence of being very carefully made, but that it could not possibly be to the advantage of the company to over-estimate the efficiency of the wheels which are submitted to them, since payment for the power is made according to the quantity of water consumed. The discrepancy between American and European tests should, according to the author, be ascribed to the different methods adopted for measuring the water, and he inclines to the belief that, if precisely the same method were employed, the American wheel would show at least as high an efficiency as its European rival. The last chapter of the book contains the theory of water-pressure engines and illustrated descriptions of some leading engines of this type, including those of Rigg, Schmid, and Hastie. On the whole, Mr. Bodmer's work forms a very complete and clear treatise of the subject of hydraulic motors other than ordinary water-wheels, and is fully up to date. Some readers may, perhaps, find fault with the large amount of mathematics employed, but this in a work like the present is a necessary evil. The action of water flowing along moving channels cannot properly be treated without the application of mathematics, and if the formulæ appear rather complex, the author has done all he could to make their application easy by a series of well-arranged tables which will be found of great service to the practical engineer.

BRICK-MAKING MACHINE.

CONSTRUCTED BY MR. WILLIAM JOHNSON, CASTLETON FOUNDRY, LEEDS.

IMPROVED BRICK-MAKING MACHINE.

WE illustrate above an improved brick-making machine which has lately been introduced by Mr. William Johnson, Castleton Foundry, Leeds. The machine is adapted for making and pressing bricks and tiles on the semi-dry method, and it finishes four bricks at once at the rate of 2,400 per hour. The brick-making material to be treated may be marl, shale, or slate débris, but the machine is equally adapted for pressing all sorts of other substances into blocks, such as cement, artificial fuel, blue billy, &c. The material is fed into dies in the granulated state and slightly damped, and the plungers then compress them with considerable force. The feeding apparatus is constructed in such a manner that the dies are regularly and densely charged, and altogether the machine turns out a sounder and better brick than is usual

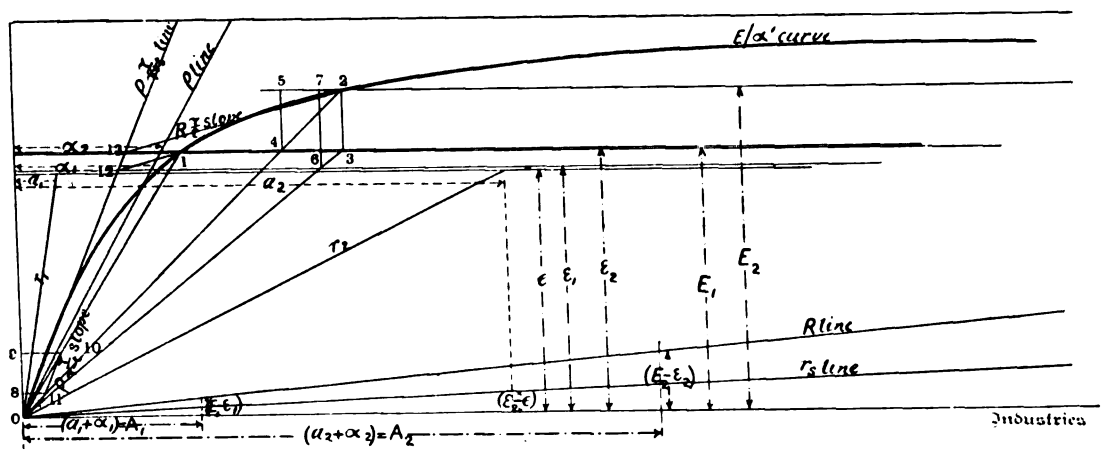

FIG. 13.

GRAPHIC CONSTRUCTIONS FOR DYNAMOS AND MOTORS.

BY PROFESSOR ROBERT H. SMITH.

IV.

(*Concluded from page* 115.)

When the series coils are placed beyond the terminals of the shunt (*i.e.*, shunt taken between brushes), the preceding constructions are modified to a slight extent only. For the generator the line whose slope is $\rho\frac{\tau}{\tau-t}$ is to be substituted for the ρ line; while in the motor construction the substituted line is to be given the slope $\rho\frac{\tau}{\tau+t}$. The reason is easily explained. The value of α^1 is now

$$\alpha^1 = \alpha + a\frac{t}{\tau} = \alpha + (A-\alpha)\frac{t}{\tau} = a\frac{\tau-t}{\tau} + A\frac{t}{\tau},$$

for the generator. Thus $\alpha\frac{\tau-t}{\tau}$ takes the place of α in the constructions already explained; and for any given value of ϵ this $\alpha\frac{\tau-t}{\tau}$ is the horizontal ordinate to the ρ line (*i.e.*, α) multiplied by $\frac{\tau-t}{\tau}$, which will be the horizontal ordinate at the same height of the line $\rho\frac{\tau}{\tau-t}$. A is still $\frac{E-\epsilon}{R}$ where R, the internal resistance, does not now include that of the series coils. The slope $R\frac{\tau}{t}$ is, therefore, now independent of the series coils' resistance, although, of course, depending on the number of turns.

Similarly for the motor the value of α^1 is

$$\alpha^1 = \alpha + a\frac{t}{\tau} = \alpha + (A+\alpha)\frac{t}{\tau} = \alpha\frac{\tau+t}{\tau} + A\frac{t}{\tau}$$

and the first term of this expression is the horizontal distance at the height ϵ of the line $\rho\frac{\tau}{\tau+t}$.

The constructions for generator and motor are illustrated in Figs. 11 and 12.

In Fig. 11, drawing any $R\frac{\tau}{t}$ line between the E/α^1 curve and the $\rho\frac{\tau}{\tau-t}$ line, its intersections with these give $(E-\epsilon)$, which again gives on the R line the value of A. From this is to be subtracted α obtained at the level ϵ from the ρ line (*not* the $\rho\frac{\tau}{\tau-t}$ line), in order to obtain a, and thus the corresponding point on the ϵ/a curve is found. Then, the r_s line being drawn (r_s = resistance of series coils), the value $(\epsilon-e)$, the e.m.f. lost in these coils, is taken from it at the horizontal distance a. This height being set downwards from the point on the ϵ/a curve, the corresponding point on the external characteristic e/a is obtained. The construction of the similar motor diagram Fig. 12 will be easily followed without further explanation.

If E_k be now taken as the height of intersection of curve E/α^1 with line $\rho\frac{\tau}{\tau+t}$ and k the slope of the E/α^1 curve at this height, these quantities have to this type of machine exactly the same relation to constancy of external voltage as in the other type. There is, however, greater difficulty in using them in solving this problem, because the position of the line $\rho\frac{\tau}{\tau+t}$ and, therefore, also the valve of k depend on t, which is the quantity to be calculated from k. It is, of course, e, not ϵ, that it is desired to keep constant.

In solving this problem we assume that, besides ρ, R, and τ, we also know r_s, the series coils' resistance. As already mentioned $R\frac{\tau}{t}$ does not now involve r_s. As the result of solving the problem, we are to find t, and this will give the length of the series coils' wire; but the resistance r_s can, of course, still be kept at the value assumed at the outset by suitably adjusting the section of the wire, or inserting a small extra resistance beyond the coils or otherwise. If this involves a waste of efficiency of practical importance, the calculation may easily be repeated with a new assumed value of r_s approximating more closely to what is found to be required.

Fig. 13 illustrates the method of procedure for a generator. The external voltage desired is e. A horizontal line at this height is drawn, and from the origin are drawn to cut it two lines at the slopes r_1 and r_2, the extreme limits of the external resistance to be used. These cut off a_1 and a_2, the extreme limits of the external current required. At these horizontal distances the corresponding values (ϵ_1-e) and (ϵ_2-e) are obtained on the line r_s, whose slope equals the series coils' resistance, and these heights being added to e give the limiting values ϵ_1 and ϵ_2 of the voltage at the shunt terminals, and from them also on the ρ line the limiting values α_1 and α_2 of the shunt current. These last being added to a_1 and a_2, give A_1 and A_2 the corresponding armature currents; and from them by help of the R line are found $(E_1-\epsilon_1)$ and $(E_2-\epsilon_2)$, and then also on the E/α^1 curve the limiting values of the armature e.m.f., namely, E_1 and E_2.

The problem is now reduced to that of drawing through the points E_1 and E_2 on the E/α^1 curve two *parallel* lines, such that their intersections with the two horizontals at heights ϵ_1 and ϵ_2 will lie on a straight line radiating from the origin.

From point 2 on E/α^1 curve at level E_2 draw the vertical 2 3 to level E_1. From the origin 0 draw the three lines 0 1, 0 2, and 0 3. The two latter lines intersect the horizontals at levels ϵ_2 and ϵ_1 at points 4 and 6. Draw the verticals 4 5 and 6 7. From the origin set off 0 8 = 2 7 and 0 9 = 2 5. Draw horizontals from 8 and 9 to intersect 0 2 and 0 1 in points 11 and 10. Join 11 and 10. This line gives the proper slope $\rho\frac{\tau}{\tau-t}$. Draw parallel to it and through the origin the line $\rho\frac{\tau}{\tau-t}$. Let it meet the horizontals ϵ_1 and ϵ_2 in points 12 and 13. Join these points with 1 and 2. The accuracy of the construction is tested by finding these last two lines exactly parallel; if they are not found to be so, the construction should be gone through again more carefully. The slope of these lines equals $R\frac{\tau}{t}$. Measure this slope and find t, the necessary number of series coils by the calculation

$$t = R\tau \div \text{this slope.}$$

The proof of the accuracy of this construction is not at all difficult, but it would occupy space unnecessarily to give it here. It will be found not difficult to make the construction so that the test for accuracy at the end shows no measurable error.

Digitized by Google

As explained, the construction gives equal voltages at the machine terminals beyond the series coils for the two extreme limits of external resistance. For intermediate resistances the voltage will be slightly higher, the rise chiefly depending on the magnitude of the internal resistance R.

Evidently the construction remains unaltered if the constant voltage is to be maintained between two points distant from the dynamo. The only change is to substitute for r_a the whole resistance of the two parts of the circuit between the shunt terminals and the points between which it is desired to maintain constant voltage.

THE ARON ELECTRIC METER.

We herewith give a report on the performance of this well-known meter, by Mr. Gisbert Kapp, M.Inst.E.E., which he has drawn up at the request of the General Electric Company, London. It would be a matter of some importance to electric companies if other meters were subjected to similar critical examination by independent practical experts.

I have subjected the Aron meter which you supplied to a series of tests extending over about ten days, and now report to you on the result of these tests. The meter consists of a pair of pendulum clocks so geared together as to register the difference in their rates on a set of dials. One of the clocks has an ordinary pendulum, whilst the bob of the pendulum of the other clock consists of a fine wire solenoid placed horizontally and swinging within a fixed solenoid of much stouter wire, through which passes the supply current which is to be metered. The fine wire solenoid is connected in series with a resistance coil, and the two form a shunt to the supply leads. The connections are so arranged that there is attraction between the shunt solenoid and the main solenoid, and consequently acceleration of the electric as compared with the gravity pendulum, the difference in rate, which is registered on the dials, being very nearly proportional to the amount of energy passed through the meter in any given time. To find this energy we have therefore to multiply the numbers registered on the dials by a coefficient which must be determined for each meter by experiment, and which in an absolutely perfect meter should be a constant for all currents and pressures within the range of this instrument. I do not know any meter in which this coefficient is absolutely constant; it varies with the amount of current, and the amount of variation is an indication of the greater or lesser accuracy of the meter. To judge of the merits of a meter it is only therefore necessary to determine the coefficient for different currents and pressures, and to compare the coefficients with each other. The more nearly the coefficients agree the greater is the degree of accuracy attained by the meter.

I have tested your Aron meter at pressures varying between 130 and 95 volts, and with currents varying between 26 and 7 amperes, both direct and alternating. In addition I have also made a prolonged test with a direct current of 0·65 amperes.

The meter is designed for a mean pressure of 100 volts, and a maximum current of 25 amperes. I found that the coefficient is practically unaffected by variations in pressure between the limits of 95 and 130 volts. The pressure was measured by a Cardew voltmeter and by a Sir William Thomson electrostatic voltmeter. I calibrated the Cardew voltmeter by means of a Clark standard cell, and its indications agreed perfectly with Sir William Thomson's instrument. The currents between 7 and 26 amperes were measured by a Sir William Thomson ampere balance, and the current of 0·65 amperes was measured by a Sir William Thomson deci-ampere balance. With the larger currents the readings were taken every quarter of an hour, and with the smaller currents they were taken at longer intervals. In this case the current was taken through a single lamp from a secondary battery ordinarily supplying 40 lamps, and was therefore absolutely constant over a period of many hours, rendering it unnecessary to take frequent readings. The tests at high voltage (from 110 to 130 volts) were made whilst charging the secondary battery, and those at normal voltage (from 95 to 105 volts) were made whilst supplying the lamps from the battery when the current was direct, and whilst supplying the lamps from a transformer when the current was alternating. The conditions of the tests were, therefore, those which obtain in the actual use of meters.

The coefficient given by Dr. Aron for this meter is 1·07—that is to say, at about 100 volts pressure between the mains one division on the uppermost dial represents 107 watt hours. I first tested the meter in exactly the condition in which it came to me, and found that for currents varying between 25 and 15 amperes the coefficient given by the maker was nearly correct. For smaller currents the coefficient was, however, incorrect, and the error increased as the current was diminished. Thus with current required for one single lamp my test gave a coefficient of only 0·97. I found that this discrepancy was due to the fact that the meter had not been properly regulated before it was sent to me. In order that a clock-meter of this kind may register accurately, it is necessary that the gravity pendulum should have exactly the same period as the electric pendulum when no current is passing. In this meter the gravity pendulum had a longer period, and consequently the meter registered, even when no current was passing. This defect can very easily be rectified, since the gravity pendulum is provided with a weight which can be screwed up or down as may be required, in order to bring the two pendulums to absolute synchronism. I found it very easy to make this regulation, and my subsequent tests were made with the meter so regulated. I mention this matter to draw your attention to the necessity of regulating every meter after it is installed.

Test of Meter with Direct Currents.—The meter being intended for a forty-light installation, it seemed advisable to test it within the limits of current which would ordinarily obtain in such an installation; I made, therefore, prolonged tests with currents of 8 and 23 amperes, which corresponded to 12 and 35 lamps respectively. The coefficients I obtained were the following:—

With 35 lamps, 1·130; with 12 lamps, 1·141. I also made a prolonged test with a single lamp, in order to determine the accuracy of the meter at the lowest current at which it can possibly be used in practice. This test is, for all meters, the most severe, since any error, however small absolutely, becomes relatively large if the current to be metered is itself very small. I found that, even at the lowest limit of current, the Aron meter gave a remarkably accurate result, the coefficient being

With one lamp ..... 1·146.

On the basis of these figures, it is now possible to form an estimate of the accuracy of the meter when in practical use. Taking the mean between the coefficients for twelve and thirty-five lamps, I find 1·1355 as the coefficient to be used with this meter. The maximum error which would obtain if the meter were always worked at the lower, or always at the higher limit of current, would then be ½ per cent., but as in practice the meter will generally be worked at intermediate currents the probable error will be less than ¼ per cent. I need hardly say that this degree of accuracy is greater than that of any gas meter, and more than sufficient for practical purposes.

Test of Meter with Alternating Currents.—As there must necessarily be some self-induction in the fine wire coil forming the bob of the electric pendulum, the shunt current must lag behind the main current, and the acceleration will be somewhat less than with a direct current representing the same energy. It will also be evident that the difference will be the greater the higher the frequency of the alternating current, so that the coefficient of the meter as found by experiment with direct currents will not be applicable if the meter is to be used with alternating currents, and a new coefficient must be experimentally determined for every frequency. I have accordingly tested the meter at two frequences which may be considered limiting values for practical work, viz., 105 cycles per second (or 12,600 reversals per minute) and 70 cycles per second (or 8,400 reversals per minute). As regards current strength, I have in both cases made the tests within the same limits as those I adopted for the direct currents, and I give the results in the following table:—

Number of Lamps supplied.		Coefficient for a frequency of 105.	Coefficient for a frequency of 70.
35	.....	1·195	1·170
12	.....	1·220	1·194

Taking, as before, the averages between these figures, I find that the coefficient to be used with this meter is

1·207 for a frequency of 105, and
1·182 for a frequency of 70.

In either case the maximum possible error is about 1¼ per cent., whilst the probable average error will be considerably smaller than 1¼ per cent. This degree of accuracy, though not so great as that found with direct currents, is still quite sufficient for all practical purposes. The energy absorbed in the meter varies with current passing through it. At a pressure of 100 volts the energy absorbed is:—

With 1 lamp	3 watts
With 12 lamps	4 watts
With 35 lamps	9 watts

My experiments lead me to conclude that the accuracy, long range, and economy of power shown by the Aron meter make it a very satisfactory instrument, both for direct and alternating currents.

THE SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

At a meeting of the London Section, on Monday, the 3rd inst., Messrs. Alfred H. Allen and W. Staveley contributed a paper on "Some Metallic Derivatives of the Phenols." The authors regretted that at this meeting they were unable to give their complete paper, but an introduction described the present process of manufacture of "neosote" from blast-furnace tar, in which they pointed out that this commercial product consisted of the homologues of phenol, and was especially valuable for its disinfectant properties. They referred to the readiness with which the sodium compounds of the phenols can be decomposed by carbonic acid, and stated that the blast-furnace gases could be employed for decomposing the sodium phenol compounds in the manufacture of neosote from the tar.

Mr. Watson Smith then read a short paper by Mr. G. Theodossieff, on "A New Process for Hardening Steel and Iron." The process consists in the employment of glycerine for tempering these materials. The specific gravity of the solution of glycerine may be varied between 1·08 and 1·26 at 15° C. by adding water according to the composition of the steel. Its temperature may also be varied between 15° C. and 200° C., according to the hardness of the metal, it being found advisable to employ a high temperature for hard steels. To increase the quenching power of the bath various salts may be added to the glycerine solution, manganese or potassium sulphate being added when a hard temper is required, and manganese chloride or potassium chloride for a softer temper. The advantages which the author claims for his method are—(1) the temperature of the aqueous solutions of glycerine may be varied within wide limits, as the boiling point of pure glycerine is 290° C.; (2) the variation in the quenching power of the solution by dissolving these salts in the liquid has a very marked influence on the degree of temper, and renders it possible to treat very different qualities of steel by this method.

Three specimens of steel were exhibited to the meeting—(1) in which no shrinkage was shown, proving that it was applicable to steel which had not been forged; (2) a specimen which had been bent on itself cold, and having a tensile strength of 65 tons and an elongation of 15 to 18 per cent.; and (3) a piece of forged steel which had been tempered by this process.

The composition of the steel from which these samples were prepared showed on analysis that it contained 0·7 per cent. carbon, 2·2 per cent. chromium, and 0·15 per cent. silicon. The author, who is engaged for the Russian Government, states that the authorities have adopted this process, and have succeeded in making a 12-inch projectile hardened by this process break through a 16-inch armour plate.

FEDERATED INSTITUTION OF MINING ENGINEERS.

On the 6th August, 1887, the late Mr. T. W. Bunning read an able paper before the North of England Institute of Mining Engineers, in which he proposed a scheme for the federation of the eight mining institutes that exist in different parts of the kingdom. Since his death the proposal has not been forgotten. The councils of the various institutes have carefully considered the matter, and the four leading institutes have federated. Independent action is left to each institute as before, but all the papers read are published in one journal. Consequently there is greater efficiency and economy in the management of the business, and a large amount of knowledge is brought to bear on the subjects discussed. The first number of the Proceedings of the Federated Institution has just been published, and contains a large amount of valuable, well-printed, and well-illustrated material in the form of papers read before the four combining institutes—the North of England Institute of Mining Engineers, the Chesterfield and Midland Counties Institution of Engineers, the Midland Institute of Mining Engineers, and the South Staffordshire Institute of Mining Engineers. The first meeting of the Federated Institution was held at Sheffield on the 22nd and 23rd ult., and the result showed the Federation to be an unqualified success, and should induce the Cornish, the South Wales, the Glasgow, and the Manchester Institutes to join the Federation.

At the inaugural meeting at Sheffield, held at the Royal Victoria Hotel, on the 22nd ult., under the chairmanship of the President, there was a very large attendance of mining engineers from all parts of the country. The first paper read dealt with the geology of the southern portion of the Yorkshire coalfield. In this paper Mr. R. Russell gave an epitome of all that is known of the geology of that district. The second paper was by Mr. G. Blake Walker, on coal-cutting machines. This was found of great interest, as it had been arranged, through the kindness of Messrs. T. & R. W. Bower, Allerton Main Colliery, and of the Wharncliffe Silkstone Colliery Company, for the members to see the coal-cutting machines at work prior to the meeting. The following is a brief abstract of Mr. Walker's paper:—

The revival in the coal trade, coupled with the fact that the thickest seams are rapidly becoming exhausted, has caused attention to be directed to thinner seams that hitherto have not been considered worth working. Interest in coal-cutting machinery is consequently reviving. The jealousy as to machinery among the miners themselves has now completely disappeared, and they are distinctly favourable to its introduction, taking care, however, that the reduction in the severity of their labour shall not bring them any reduction in the actual money value of it. Coal-cutting machines have hitherto been used for three purposes—for heading, for holing, and for bringing down the coal. For heading, the Stanley machine is the only machine that has been made a practical success. It may be considered to have solved the problem of rapid progress, the progress made with this machine being 1 yard an hour. In a trial of twenty-four hours it cut 64ft. 6in. Machines for holing or undercutting the coal have to comply with a number of conditions. A machine for this purpose must be light, so as to be managed by two men working in a confined position, and strong, so as not to be injured by falls of the roof or by rough usage. It must be narrow and simple; it should clear its own cut, and be able to cut into the straight face at the start without having a hole made for it. There should be a reserve of power, so as to enable the machine to cut through nodules of pyrites or other exceptionally hard substances. Lastly, the cutting tools must be simple, and easily changed and sharpened. Amongst the most successful compressed air machines may be mentioned Mr. W. Firth's pick, a machine introduced thirty years

Digitized by Google

ago, and still at use at the West Ardsley Colliery; Baird's endless chain machine, which has been largely used in Scotland; and the Rigg & Meiklejohn, Gillott & Copley, and the Winstanley rotary machines. The last is not at present in use, as it has not succeeded in cutting anything very hard. It has, however, many good points, especially that of being able to cut into the face. The Rigg & Meiklejohn machine cuts from front to back on the level of the foot of the seam, whilst the Gillott & Copley machine works in the opposite direction, and thus brings out its *debris* if the cut is above the floor. In Baird's machine the cutting is done by an endless chain with cutters attached, driven round an arm extending under the coal from 3ft. to 5ft., as required. In eight to ten hours this machine will cut 2ft. 9in. deep into 100 yards. Of American machines actuated by compressed air, the Legg coal-cutter appears to be the most successful. A number of electrical coal-cutters have been used in America, the Sperry, Bain, and Lechner machines appearing to have met with success. A new machine has been successfully tried at Messrs. T. R. & W. Bower's Allerton Main Colliery, and in ordinary working averages 150 yards per shift of eight hours. In comparing the actual cost of coal-cutting by hand and by machinery, experience shows that in a 3ft. seam the quantity of slack made when the holing was done by hand was 25 per cent., as compared with 15 per cent. when done by machine. In a seam 1ft. 6in. thick the corresponding figures would be 45 per cent. and 30 per cent. respectively. A satisfactory performance in working a coal face by hand would be 100 yards per eight hours shift. The general result shows that, when machines are used, there is a saving of 8½d. to 1s. 6d. per ton, about two-thirds of which is due to the reduction in the quantity of small coal produced.

The last paper was one by Mr. A. T. Snell on the distribution of energy over large areas in mines by electricity. The paper was elucidated by effective diagrams, and was rendered of special interest from the fact that arrangements were made for the members to visit prior to the meeting St. John's Colliery, Normanton, where the author of the paper, representing Messrs. Immisch & Co., described the electric pumping and hauling plant installed by his firm. It is to be regretted that time did not permit any discussion of the papers. As this meeting was the initial gathering of representative mining engineers of the different districts, a discussion could not fail to have elicited information of value.

The meeting was followed by a dinner, which was attended by two hundred members of the Institution, with some of the leading men of Sheffield as guests. Mr. C. E. Rhodes, President of the Midland Institution, was in the chair. Later in the evening there was a reception given by the Mayor of Sheffield and the Master Cutler at the Cutlers' Hall. A large number of ladies and gentlemen were invited to meet the engineers, and a room was set apart for an interesting exhibition of mining appliances. Amongst the novelties the Thornebury miner's lamp attracted a good deal of attention. In this lamp the air ingress is entirely separate from the egress of the products of combustion. As the whole of the air supply must pass through the flame a greatly increased light is given, and as the gas can never become ignited within the gauze cylinder it is absolutely safe under all conditions.

A number of varieties of Ashworth's patent Hepple-white-Gray safety lamp were also shown. This form of lamp is of especial value for making quick tests for either low or high percentages of firedamp.

The Yorkshire Engine Company, Limited, exhibited one of their coal-cutting machines with cylinders 9in. in diameter and 9in. stroke. The total width of the machine, exclusive of the cutter wheel, is 3ft. 3in., and its weight complete 24cwt. It will undercut 39in. in hard coal at the rate of 12 yards an hour, the pressure of air required being 30lb. per square inch. It can be worked by two men, who also take up and lay down the rails on which it works.

Messrs. J. Davis & Son exhibited various improved mi ie surveying instruments and anemometers. A number of solid forged wheels were shown by Messrs. John Brown & Co.; a patent wheel lubricator was shown by Messrs. Lampen & Co.; steel pit bars and props by Mr. W. Firth; mining tools and disintegrators by the Hardy Patent Pick Company, Limited; cartridges by Messrs. R. Roper, Son, & Co.; and compensating metallic pistons by Messrs. W. Buckley & Co.

Thursday, the 23rd, was devoted to excursions. Three routes were included in the programme. The first included visits to the Aldwarke Main Colliery, Denaby Main Colliery, and the Denaby Main new sinkings; the second excursion was to the Wharncliffe Silkstone Colliery and the Lidgett Colliery; and the third was to St. John's Colliery and Allerton Main Colliery. In each case the mining engineers were very hospitably received, and, notwithstanding the inclemency of the weather, each excursion was largely attended.

THE UTILISATION OF SLAG.

On Wednesday, the 29th ult., at the Society of Arts, Mr. Gilbert Redgrave read a paper on the above subject, of which the following is a brief abstract:— The total quantity of slag produced in the manufacture of cast iron in the United Kingdom amounts to 18,000,000 tons per annum, while considerable quantities of slag are also formed in the new processes of steel manufacture and in copper smelting. Mr. Charles Wood some years ago introduced many ingenious methods for dealing with slag, and of these the various processes for utilising molten slag by casting it into blocks, the production of slag sand, and the preparation of bricks and mortar from this sand are the most important. In recent times the casting of blocks has made important progress under the Tees Scoriæ Brick Company, chiefly in the production of granitine paving setts, in which the cleaved rough surface of the slag brick is exposed to wear instead of the smooth polished surface. These blocks, being non-porous, are very durable, and at Middlesbrough a road surface exposed to heavy traffic for eleven years is still in good repair.

The annealed slag has also a strong affinity for Portland cement, and this fact has been turned to practical account by the Jones's Annealed Concrete Company, of Middlesbrough, who employ this material for paving purposes. Broken slag is also in use in various parts of the country for road-making. Slag-wool or silicate cotton, also originally obtained by Mr. Charles Wood, is also an important application of blast-furnace slag. It is obtained by causing a jet of steam to impinge upon the stream of molten slag as it issues from the furnace, and has the following properties, viz.:—(1) It is extremely light and is absolutely fireproof; (2) it is a good non-conductor of heat and of sound; and (3) it is so porous that it will absorb large quantities of water and readily retains the same for a considerable time. The slag-wool is moreover an antiseptic, and is being used for medical purposes. Large quantities of cement are also now made from slag-sand, without the addition of Portland cement, by mixing it with 25 per cent. of lime. In order to ensure a successful cement the mixture is ground in a machine of special construction termed a "homogeniser." The specific gravity of this cement is very low as compared with Portland cement, while the time occupied in setting is comparatively long. For purposes of storage it also compares well with Portland. By exposure to the air it absorbs carbonic acid more rapidly than does Portland cement, but it does not deteriorate greatly in tensile strength by long exposure. For works in water, owing to the closeness of its particles, the cement appears to be particularly well adapted. Crushed slag can be used as concrete with this cement for making sea walls. It has been in use abroad for many years, but the system of cement testing in England has militated against it having a fair trial in this country. In Germany, used alone or mixed with Portland cement, it is held in great favour. The author then gave an outline of the utilisation of Thomas slag as a manure, and pointed out the astonishing rapidity with which this fertiliser has been introduced into German agriculture, where it has exceeded the total available native production of the slag, giving rise to a large import from this country and Austria. He concluded by urging the English farmer to follow the example set in Germany, as at its present price Thomas slag meal can be obtained in this country at about half the cost of superphosphate. He added that it seemed sad that we should be importing phosphates from America in large quantities and exporting a good home-made phosphate to the Continent.

In reply to the questions which arose out of the discussion which followed, Mr. Redgrave stated that the presence of calcium sulphide in the slag was of very small importance, as up to 3 per cent. it produced no injury at all, its effect being to render the cement slower in setting.

Notes.

JAPANESE LACQUER FOR SHIPS' BOTTOMS.

The uses to which the Japanese put the lacquer for which their country is celebrated are very numerous both from an artistic and an industrial point of view. High class artistic work is most expensive, and only rich people can afford to indulge in it, the older work especially being highly prized. For domestic and industrial purposes the transformations which can be worked on paper and wood by the application of lacquer are very wonderful, and render it most indispensable for ordinary use. Some few years ago the Japanese Government decided on lacquering the bottoms of all their iron ships, and the results proved that corrosion was most effectively prevented, but the process does not seem to have been applied to any foreign ship until about two years ago, when the attention of the captain of a Russian frigate was directed to it, and lacquer was applied both to the iron and the zinc parts of the bottom. To the latter it was found that the adhesion of the lacquer was very slight, but on the iron, or rather steel, it was found that it was in an extraordinary good state of preservation, so much so that it could not be stripped off except by being scraped with a sharp instrument, and from the experience thus gained it has been decided to substitute iron on the part where zinc had been used. It would be interesting to hear the result of an experiment of the bottom of a British war-ship, and it might be worth the while of the Admiralty to arrange for this being carried out.

THE CITY OF LONDON AND SOUTHWARK SUBWAY.

The progress of these works has been very rapid during the last six months, and they are now very nearly complete. The wet gravel bed at Stockwell has been driven through, and one of the tunnels through it has already been finished. In a short time the various stations will be ready. Messrs. Mather & Platt's electric locomotive and train have been running for some time along part of the line already laid down, and Mr. Greathead, the engineer of the company, reports very favourably as to the working.

THE THEORY OF ACCUMULATORS.

M. Drzewiecki attacks the recognised theory of accumulators, but his own grounds seem assailable. He says that sulphate of lead cannot be formed on both plates on discharge, or they would become white. As a matter of fact, only about 5 per cent. is really converted into sulphate, 95 per cent. of the coating remaining idle; hence the colour does not change much. He has next got hold of the old fallacy that lead sulphate is inoxidisable. He will find it is only a question of contact. If properly pressed against the plates it goes into PbO_2 on one and Pb on the other. There seem to be no reasons to believe that basic sulphates are formed in the presence of fairly strong acid.

EDINBURGH EXHIBITION, 1890.

The applications for space in this Exhibition closed on the 31st ult., and it is estimated that the amount applied for is about double that available in the buildings at present being erected, so that an additional annexe has become a necessity, and will be proceeded with at once. The Exhibition promises to partake much more of an international character than any recent one in this country, very large demands for space having come from abroad, especially from France and Italy. In its most prominent feature—that of the applications of electricity—it will surpass anything hitherto seen, while new departures have been taken in several directions with the view of increasing its attractiveness. The Forth Bridge, which may be said to have called the Exhibition into being, will be represented in the grounds by a model in wood to a large scale, and, probably, additional models of various parts, showing the methods of construction adopted, will illustrate the history of this vast undertaking in a way both attractive to the public and valuable to the engineer. Railway exhibits generally will take a prominent place, a representative collection of early and late locomotives having been promised by the principal British railways, while negotiations are still in progress with leading American locomotive engineers with a view to their sending specimens of their best productions, to compete in open trial with our own under normal running conditions on an English line. The addition of a Fine Art Section has been decided on, and the long covered way which connects the two main buildings will be partly utilised for this, especially for works of sculpture. In the Electrical Section, one branch, of which little has been seen hitherto, electric welding, will be shown on a large scale, and among many other important exhibits a complete historical collection of telegraphic appliances, promised by the British Post Office, will doubtless prove a great attraction. The arc lighting of the buildings and grounds has been entrusted to the Brush Electrical Engineering Company, and the incandescent system to Messrs. King, Brown, & Co., Rosebank Electric Works, Edinburgh. Messrs. Galloway, of Manchester, are to supply the five principal boilers necessary for the steam power.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents).")

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

20th January, 1890.

963. Drey, O. — Pile cutting machines.
967. Tranter, T. M. — Breechloading small arms.
969. Field, T. C. — Rotary engine.
971. Wardle, J. — Steering ships.
973. Sayers, W. B. — Lubrication of journals.
976. Furnival, Tudor, Byway, & Grimshaw — Paper cutting machines.
978. Knowles, T. — Steam engines.
986. Hall-Brown, E. — Compound engines.
989. James, W. — Sight-feed lubricators.
990. Buckley, W. — Lathes.
995. McQueen, P. — Boat detaching gear.
998. Haag, S. — Propelling vessels.
1003. Boult, A. J. — Lubricators (*Andersson & Blom*).
1005. Preiss, A. — Joint for railways.
1006. Thompson, W. P. — Pumps for viscous substances (*Lankelma*).
1008. Norl & Tillett — Wire ropes.
1009. Berr, F. — Breaks for steamers.
1010. Edwards, E. — Opening machine for cotton (*Josephy*).
1013. Guy, J. P. — Machines for making earthenware articles.
1014. Caird, D. — Metal barrels.
1019. Ainley & Oakes — Machinery for cutting holes.
1021. Moore, J. — Propelling screws.

21st January, 1890.

1030. Eves, J. V. — Frames for spinning flax.
1032. Hall, W. — Enlarging coal pit shafts.
1034. Hughes, D. — Machinery for "wood-wool."
1035. Szarbinowski, F. M. — Snow ploughs.
1039. Gimson, Gimson, Gimson, & Gimson — Burnishing machines.
1043. Edwards, W. — Sharpening files.
1044. Parkin, Frear, & Davie — Valve gear.
1045. Hill & Smith — Breechloading small arms.
1050. Bollé, C. — Dynamo-electric machines (*Gutmann*).
1057. Robertson, Orchar, Adie, & Robertson — Sewing machines.
1061. Leverkus, K. — Horse-power gauges.
1063. Holker, W. — Slide valves.
1064. Bedford & Rodger — Metallic packings.
1075. Tellering, C. — Machine for making hollow metal goods.
1077. Thornycroft, J. I. — Indicating speed of rotating shafts.
1078. Sauvée, A. — Mountings for guns (*Canet*).
1079. Baylis & Denton — Permanent way.
1080. Elster, Young, & Knapp — Nut locks.
1095. Smith, E. F. — Veneer cutting machines.
1096. Watson, Gelston, & Weed — Screw-threaded rods.
1099. Wells, C. — Steam engines.
1100. Paterson, H. C. — Furnaces with forced draught.
1101. Paterson, H. C. — Furnaces.
1103. Lässoe, V. F. — Duplex rudders.
1104. Goddard & Radford — Propelling boats.
1105. Newton, P. A. — Printing machines (*Hoe*).
1111. Moore, C. T. — Typewriting machines.
1112. Connolly, Altman, Altman, & Altman — Machines for picking skins.
1114. Gathmann, L. — Loading ordnance.
1116. Procter, Middleton, Fraser, & Carter — Manufacture of bricks.

22nd January, 1890.

1120. Parsons, C. A. — Steam turbines.
1122. Wilson, T. E. — Concentration and distillation of liquids.
1124. Helliwell, R. B. — Lubricators.
1125. Eves, J. V. — Frames for spinning flax.
1129. King, J. T. — Blast furnaces (*Kennedy*).
1134. Dixon, S. (of the Firm of Kendall & Gent) — Drilling machines.
1135. Fairweather, W. — Fringing machines.
1136. Edmunds, L. R. — Screw heads and nuts.
1139. Hurdle, G. — Self-lubricating pulleys.
1143. Chadburn, W. — Engine-room indicator.
1144. Betten, H. — Motor engine.
1150. Lindner, O. — Hot-air and gas engines.
1160. Krnka, K. — Repeating rifles.
1161. Turner, T. — Blast furnaces.
1162. Dansey, H. — Valve gear.
1164. Tavernier & Casper — Feeding boilers.
1169. Smith, M. J. — Wire netting machinery.
1170. Brown, C. A. — Furnaces for burning tan.
1171. France, E. — Knitting machines.
1179. Defalque & Chatelain — Railway axle boxes.
1180. Berthon, E. L. — Anchors.
1181. Horn, W. W. — Steam engine valve (*Haven*).

23rd January, 1890.

1191. Clegg (of the Firm of Asa Lees & Co., Ld.) & Moorhouse — Mules.
1192. Bailey & Lindemann — Pumping engines.
1193. Imray, H. — Rolling composite tubes (*Moerchen*).
1194. Morton, J. — Brick machinery.
1196. Barker, W. — Boot-finishing machine.
1197. O'Donnell & Smith — Interlocking railway levers.
1198. O'Donnell & Timmis — Railway signalling wires.
1199. Woodville, G. — Machines for pressing hay.
1200. Moore, J. G. — Valves for engines.
1202. Wood, W. — Steam cylinder drain cocks.
1204. Carter, C. — Tapering bolt holes in shaft couplings.
1206. Chumard, M. — Lifting jacks.
1207. Thompson, W. P. — Moulding boxes (*Brunelli*).
1211. Higgins, J. — Combined exhaust steam pipe and air ejector for locomotives.
1213. Grant, A. M. — Metallic packings.
1214. Kyte, G. — Hydrant valve casing.
1215. Walker, H. — Annealing furnaces.
1217. Smith & Dight — Lifting and lowering crossings, &c., of permanent ways.
1218. Kerby, J. T. — Car axle lubricators.
1223. Hyde, G. T. — Axle boxes (*Brewer*).
1232. Booth & Hardcastle — Safety device for lifts.
1234. Mannesmann, R. — Regenerative gas furnaces.
1235–6 Mannesmann, R. — Compressing air.
1239. Bethmont, D. — Instantaneous production of vapour from water.
1240. Scott & Williams — Knitting machinery.
1249. Phalp, O. — Anchor and oil distributor.

24th January, 1890.

1250. Lorrain, J. G. — Pistons (*Carré*).
1254. Wright & Nettleton — Shuttle boxes.
1257. James, W. I. — Knitting machines.
1258. Hallas, C. G. — Rolling rods.
1260. Whitworth, T. S. — Carding engines.
1263. McDougall, N. — Force pumps.
1264. Settle, W. — Drills for mining.
1274. Walker, W. — Blast pipes of locomotives.
1276. Legrund & Nottingham — Producing motive power.
1278. Sleat & Skelton — High-speed engine.
1284. Imray, O. — Furnace fires (*Mannesmann & Mannesmann*).
1285. Imray, O. — Gas producers (*Mannesmann & Mannesmann*).
1290. List & Dick — Screw propellers.
1294. Tozer & Tozer — Manufacture of buffer cases.
1297. Cresswell & Heslop — Feeding printing presses.
1301. Wells, C. — Steam engine.
1304. Younghusband, S. S. — Valve gear.

25th January, 1890.

1309. Rawstron, F. W. — Knitting machine.
1311. Gant & Moy — Releasing gear for boats.
1316. Andrew & Birks — Forging elongated shot and shell.
1317. Hassel & Holt — Carding engine flats.
1320. Avery & Avery — Weighing machines.
1327. McQuiston, W. — Nut locks.
1336. Menzies & Co. — Detaching ships' boats.
1337. Burgon & Marshall — Driving shafts.
1338. Fielding & Fielding — Jacquard harness.
1339. Hollingdrake, R. — Steam boilers.
1345. Boss, M. P. — Stamp batteries.
1348. Steinmüller & Steinmüller — Steam generators.
1352. Marjoribanks, D. S. — Manufacture of shells
1358. Boult, A. J. — Lathes (*Von Pittler*).
1359. Petibon, — — Locking railway points.
1361. Boult, A. J. — Nut locks (*Harris*).
1364. Edwards, E. — Fleece-dividing machinery (*Josephy*).
1368. Ponto, W. J. — Car coupling.
1369. Fricker, G. C. — Cleaning and annealing iron.
1370. Wolseley, F. Y. — Sheep-shears, horse-clippers, &c.

ELECTRICITY.

20th January, 1890.

993. Edmundson & Clark — Incandescence electric lamps.
1026. Boult, W. S. — Accumulator switches.

21st January, 1890.

1028. Thompson, W. P. — Alternating currents (*Gutmann*).
1031. Von Peichl, J. — Electric compass.
1068. Lückhoff & Hungerbühler — Conductors.
1072. Binswanger, G. — Electrical switches.
1094. Lake, H. H. — Storage batteries (*Ewing*).
1106. Carpenter, H. H. — Electrical distribution.
1110. Hitchcock, C. A. — Batteries (*Burnley*).

22nd January, 1890.

1159. Philips, T. W. — Insulators.

23rd January, 1890.

1226. McMullen, J. A. — Incandescent electric lamps.

24th January, 1890.

1266. Thompson, Sir W. — Mariner's compass.
1280. Baker, C. L. — Switches.
1281. Ernst, V. H. — Secondary batteries. (28th September, 1889.)
1296. Berry, A. — Electrically recording the passage of trains.
1302. Trotter, A. P. — Calculations relating to supply of electrical energy.
1306. Smith, C. — Galvanic dry elements (*Hellesen*).

25th January, 1890.

1347. Coad, T. — Fluid for primary batteries.

CHEMISTRY.

20th January, 1890.

981. Grimshaw, H. — Recovery of tannin from leather.
983. Grimshaw, H. — Soap.
984. Grimshaw, H. — Generation of carbon dioxide.
985. Grimshaw, H. — White pigment.
1015–6. Ellershausen, F. — Soda and potash.
1017. Dammann, W. — Reudering tar-oils soluble in water.
1022. Walrond-Smith, T. — Water gas.

21st January, 1890.

1053. Grimshaw, H. — Recovery of zinc.
1062. Knowles & Knowles — Azo colours.
1117. Massignon & Watel — Chromates.

22nd January, 1890.

1126. Hazlehurst & Pope — Spent soap lyes.
1157. Young & Pearn — Dyeing and bleaching.

23rd January, 1890.

1227. Miller, E. C. — Anti-friction alloys (*Magnolia Anti-Friction Metal Company*).
1237. Mannesmann, R. — Illuminating gas.
1238. Mannesmann, R. — Water gas, &c.
1246. FitzGerald & Falconer — Chlorine.

24th January, 1890.

1283. Imray, O. — Production of coke (*Mannesmann & Mannesmann*).
1300. Leigh, H. H. — Barium oxides (*De Brochocki*).

25th January, 1890.

1355. Haswell & Haswell — Coating iron, &c.

MISCELLANEOUS.

20th January, 1890.

1001. Nevill, W. H. — Artificial fuel.

21st January, 1890.

1037. Bowles, R. C. M. — Mechanical telephones.
1087. Goodall, T. — Boiling esparto grass.

22nd January, 1890.

1127. Dowson & Taylor — Fire extinguishing apparatus.

24th January, 1890.

1308. Lawson, C. — Gas meters.

25th January, 1890.

1346. Sugg, W. T. — Ventilating apparatus.
1349. Wise, W. L. — Gasification of fuels (*Solvay & Semet*).

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1888.

17007. Hook.
17496. Whitehead.
18552. Clifford.

1889.

944. Paris.
1035. Bailey & Bailey.
1070. Holmes.
1209. Lowry.
1286. McPhun.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Steam Boilers.—*J. L. White & H. S. White, East Cowes, Isle of Wight.*—The boiler consists essentially of coiled tubes, arranged in an upright position, and communicating with steam and water chambers at their upper and lower ends. The outer shell of the boiler consists of a double casing of metal between whose plates air is made to circulate. The space enclosed by the casing is divided into three longitudinal flues by rows of tubes arranged close together and connected at their ends with the steam and water chambers. In each flue are rows of double spiral tubes, placed in the flues with their axes vertical, and communicating at the top and bottom to the steam and water chambers. The steam chamber consists of a large tube fixed longitudinally at the top of the boiler, and the water chamber consists of two similar tubes placed longitudinally at each side of the bottom of the boiler. The products of combustion pass along the central flue to the back of the boiler, and then back again to the front by the two outer flues, one upon each side of it. The products of combustion thus strike against the coiled tubes and the tubes forming the division of the flues, imparting to them their heat, and so generating steam. Claim: The improvements hereinbefore described in such steam boilers as consist of tubular coils communicating at their upper ends with a steam chamber or steam chambers, and at their lower ends with water chambers—that is to say, the construction in such boilers of a middle flue or middle flues and sides, or return flues by means of tubes communicating with the said steam and water chambers.—No. 6934. April 25th, 1889. 11*d*.

Centrifugal Pumps.—*W. Beaumont, Stockport.*—The following structural alterations are made in centrifugal pumps, to obviate priming, &c. The wheel and its shaft are made preferably of brass in one piece. The vanes of the wheel are made straight, and are fixed radially to its axis, the inner ends being slightly wider than the outer ends. The wheel is fitted into a flat shell formed in halves, scroll like, so as to leave space between the periphery of the wheel and shell, which widens gradually towards the outlet formed on the side. The axis of the wheel is vertical, and a long bush is formed in the top half of the shell for its shaft. The lower half of the shell is formed with a hole concentric to the axis of the wheel for the inlet. To the inlet is attached a short piece of vertical pipe containing a lift valve if required. Three claims are made for the improvements described.—No. 2603. February 14th, 1889. 6*d*.

Reciprocating Rotary Motion.—*W. Crook & E. Entwistle, Blackburn.*—The reciprocating rotary motion is obtained from a direct rotary motion in the following manner. The shaft which receives the reversible motion is arranged between two other shafts geared together by a gear wheel upon each so that the motion of each shaft is in contrary direction. Upon each of the two outside shafts is fixed another gear wheel with only half of its periphery with teeth. The teeth of these segmental gear wheels engage in a wheel upon the centre shaft in such a manner that as one segmental wheel engages with it the other goes out of gear and so gives the centre shaft a reversible motion. One claim is made for the motion described.—No. 3768. March 4th, 1889. 6*d*.

Lubricators.—*R. W. Anderson, Liverpool.*—The invention refers to that class of oil cup known as a "sight feed," the usual form of which consists of a metal cover and bottom with a glass body connected by means of a central tube. In the illustration Fig. 1 shows the appliance in sectional elevation; Fig. 2, sectional plans; Fig. 3, a side elevation of the appliance; and Fig. 4, a plan. The top C and the bottom D are connected by a tapered tube T. A glass cylinder A is grasped between the top and bottom and constitutes the container. In the tube T is a plug V, which has a number of openings and grooves corresponding to other openings in the tube. The plug V is retained in its position by a plate J turned under the collar I. The plate J

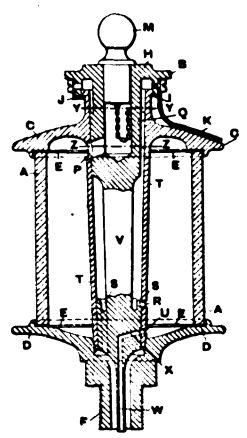

FIG. 1.

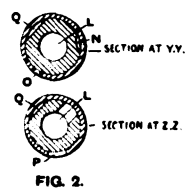

FIG. 2.

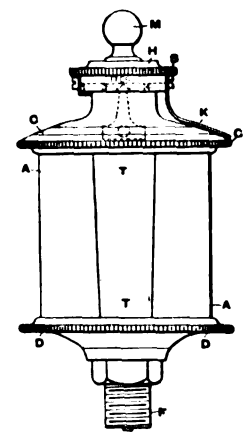

FIG. 3.

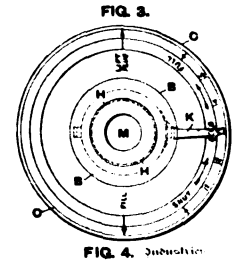

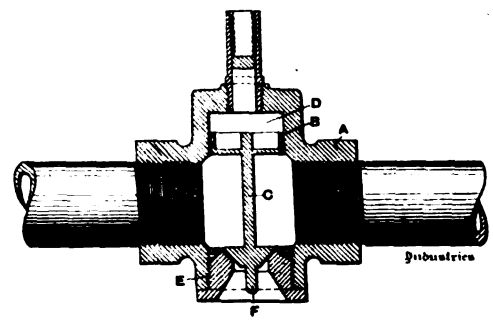

FIG. 4.

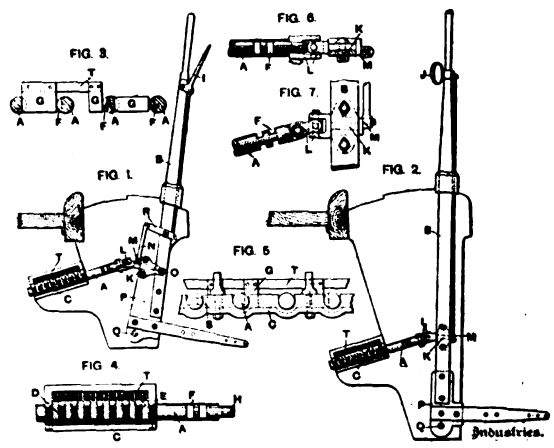
and collar I are cut away so that when the plug is turned into a certain position it can be removed from the tube. To fill the lubricator the plug V is moved until the holes L and P correspond; the plug M is then removed and oil poured in. The air displaced by the oil escapes by the hole O and the groove N. The oil is fed to the lubricated part through the hole U and passage X. The passage X and the hole U communicate direct as shown or by a tapered groove which gradually diminishes in size as the plug V is turned to regulate the flow. Air to take the place of the oil fed enters by the passage Q and the hole R, from which it ascends in bubbles to the top of A. An index arrow K is attached to the plug V to indicate the various positions required and marked upon the top C. Nine claims are made for the lubricator as described.—No. 4584. March 16th, 1889. 8*d*.

Coverings for Rollers used in Textile Machinery.—*J. Shepherd, Stockport.*—To obtain a sufficiently firm and elastic covering for the top rollers used in connection with textile machinery the inventor employs a very thin tough paper, in the form of tape, of any required length and breadth, and by the aid of suitable appliances winds the paper round that part of the roller intended to be covered. A sufficient quantity is wound to form a firm but slightly elastic body. The paper is secured to each other and the roller by glue or any suitable cement. The outer covering of paper is varnished with a quick drying varnish made of shellac and methylated spirits, to keep the rest from the bad effects of oil or damp, and to leave a smooth surface that will not collect dust and dirt. Claims: (1) Covering top rollers used in textile machinery, of whatever material or materials the rollers may be made or in parts composed, with strips of thin tough paper in the manner and for the purpose described; (2) continuous winding layer upon layer of thin tough paper upon rollers forming an outer covering of an elastic nature due to the number of fine interstices between the unattached parts that are set closely together; (3) varnishing the outer surface of paper-covered rollers used in connection with textile machinery as a means to prevent absorption of oil or grease.—No. 4592. March 16th, 1889. 4*d*.



Grab Dredger Buckets.—*E. Y. Harrison, New South Wales.*—The dredger here described is constructed with two jaws, which are hinged to a common bolt. The hauling chain, which also serves the purpose of closing the jaws, is attached to the inside of one of the jaws and is passed round a pulley attached to the inside of the opposite jaw, and from that to a central pulley mounted upon the common hinge bolt. Thus, by hauling upon the chain, the jaws will be closed. The chain for opening the jaws is connected by two branch chains to the outside of each jaw, so that if the weight of the dredger is thrown upon the opening chain it draws the jaws back upon the common bolt and opens them. If the jaws of the dredger consist of prongs, the opening chain is attached by its branch chains to two plates of metal, from which other chains pass and are connected to each prong. Four claims are made for the dredger described and the modified means of opening pronged-jawed dredger buckets.—No. 11220. July 12th, 1889. 8*d*.

Fire Extinguishing Apparatus.—*J. R. Gray, Ayer, Middlesex, U.S.A.*—This is an improved fire extinguisher of the class called "sprinklers." The illustration gives a longitudinal section of the sprinkler. The casing A is adapted to be connected to the supply pipes. The casing is provided with a mouth E for the discharge of water when in operation, and a chamber D for the reception of the piston B of the valve C. The chamber D communicates above the piston B with the interior of the casing A.

In the top of the chamber D is fixed a pipe with a fusible plug. Water supplied to the casing A by the pipes exerts pressure upon each side of the piston B and upon the upper surface of the valve C, thus keeping the valve firmly upon its seat. When sufficient heat occurs to melt the fusible plug, the water escapes from the top of the piston B faster than the vent supplies it; thus the entire pressure upon the under surface of the piston is effective, and being greater than that upon the top of the valve C causes the valve to rise and the appliance to come into action. Five claims are made for the extinguisher described.—No. 12428. August 6th, 1889. 8*d*.

Interlocking Apparatus for Railways.—*W. F. Burleigh, London.*—Improvements are here described in the method of locking by the catch handle. They consist of a form of locking shaft which is attached to the lever in such a manner that to release the lever the shaft is given a partial turn on its axis by the catch handle, whilst the lever is pulled forward. By giving the shaft a partial turn the locking keys are shifted, and made to lock other levers. The illustrations show Fig. 1 a side elevation of the appliance with the locking trough in section; Fig. 2 shows a modified form of the catch lever and its connections; Fig. 3 shows the manner of applying the locking keys; Figs. 4 and 5 are portions of the locking trough; and Figs. 6 and 7 details of the appliance. Referring to the figures, A is the locking shaft, which is given a quarter turn about its axis by the catch handle I. The shaft A is connected to the lever B by a knuckle-joint O. In the shaft A are cut grooves F to receive the locking keys G, which are mounted by the slides T in the locking troughs C. To move the lever backwards or forwards, the shaft A is turned a quarter turn by pressing or otherwise working the catch handle I. By turning the shaft A the keys G are moved out of the slots

F, and rest against the fall part of the shaft A, and permits it to be withdrawn in moving the lever B forward. The locking keys, as they are shifted by one shaft, are made to lock others as shown in Fig. 3. Claims: (1) A shaft attached to the lever and arranged so as to be turned by the catch handle and moved by the lever; (2) the use of the universal or gimbal joint, herein figured L, for the purpose of turning by the catch handle a shaft or its equivalent attached to and moved by the lever; (3) arrangement of connecting slides in locking trough substantially as shown on Fig. 4; (4) apparatus arranged and combined substantially as described and illustrated on the accompanying drawings.—No. 1653. January 30th, 1889. 8*d*.

Steam Boilers.—*R. Tatham, Rochdale.*—The invention consists of an appliance for ensuring the proper circulation of the water, and to facilitate the removal of dirt, sediment, &c., from the boiler. To effect these objects the inventor arranges inside the boiler a number of brushes, which may be spiral, and mounted upon a shaft, flat and mounted upon endless bands, or any other suitable form. These brushes are made to revolve,

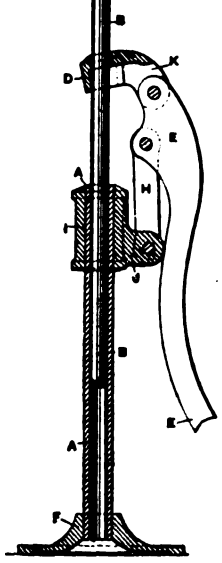
Digitized by Google

oscillate, or work, so as to sweep the tubes and sides of the boiler and remove the sediment towards the mud-hole. The brushes are connected through stuffing boxes to operating mechanism outside the boiler. The brushes may be mounted upon the edges of a helical blade, so that the motion of the blade upon its axis causes the water to circulate in the boiler. Ten claims are made.—No. 1744. January 31st, 1889. 8*d*.

Pulley Blocks.—*T. Deer, Birkenhead.*—The block is constructed to permit the rope to travel in any direction without increasing the friction on the block. The block consists of a suitable framing, in which are mounted a number of small grooved wheels, whose axis are in the same plane and at right angles to radii drawn from a common centre. The rollers are arranged around this common centre equi-distant from each other, and so that the edges of their grooved faces just touch each other, and form a continuous and circular bearing face for the rope. The rope when drawn through this hole must bear upon one or more of the pulleys, which exert little resistance to its motion. The top half of the frame with a number of the top pulleys can be lifted upon a hinged joint, to insert a long length of rope and other purposes. Claims: (1) A bearing or pulley device for running gear, in which a series of pulleys, arranged radially round a common axis and capable of rotation in planes approximately radial to said axis, have the inner portion of their peripheries so located as to form a continuous movable bearing surface round the axis; (2) an improved bearing or pulley device for running gear consisting of a series of pulleys arranged radially as described about a common axis, a suitable frame or bracket supporting said pulleys and having a portion, containing one or more of the pulleys, capable of being moved aside or detached from the rest, and means for securing such movable or detachable portion into position; (3) the improved bearing bracket for running gear constructed as a whole as herein described and for the purpose specified.—No. 3343. February 25th, 1889. 6*d*.

Lifting Jacks.—*A. Jackson, Rockford, Essex.* (*C. Jackson, Carrollton, Illinois, U.S.A.*).—The lifting jack here described is for the purpose of lifting and holding in a raised position the parts of carriages and other light bodies. Fig. 1 shows a vertical section of the jack; Fig. 2 a side elevation. The rod B is free to rise and fall in the socket A. The cross-bar G of the rod B is placed under the part to be lifted, and the hand lever E raised, causing the ring D to assume a position lower down the rod B.

Fig. 1.



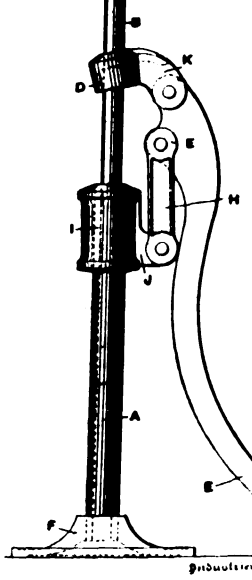


Fig. 2.

When the lever E is depressed, the ring D is tilted and grips the rod B, and a further depression of E lifts it and the load upon G. To keep the rod B in its raised position, a flat ring (not shown) of rectangular section, and having upon its under surface a projection which rests upon the bush I, is tilted by the projection and grips the rod in the same manner as the ring D. Three claims are made.—No. 7190. April 30th, 1889. 8*d*.

Slide Valves.—*J. Marshall, Gainsborough.*—The object of this invention is to provide a slide valve for steam which shall work with a minimum amount of friction and which offers a means of compensating for wear. The valve is made with its working and opposite faces parallel and with its ends at right angles. The two opposite sides of the valve are inclined inwardly from the working face towards the top or opposite face, leaving, however, a flat face at top. The ends of the valve are recessed or made hollow and a passage is made through the centre of the valve extending from the working face to the top. The valve slides in a cover bolted down to the port face of the chest and corresponding in internal shape with the external shape of the valve. In the cover channels are formed corresponding to the inlet and exhaust ports in the port face so that as the valve in its travel uncovers the ports the motive fluid enters these channels and equilibrates the pressure, the exhaust passing through the central passage in the valve to the exhaust outlet. The outside depth of these channels corresponds with the depth of the ports on the cylinder face, and the valve is made considerably narrower, so that these channels act also as supplementary motive fluid passages. In order to relieve the cylinder from excessive pressure and water of condensation the cover is provided with passages situated over the inlet ports in the cylinder. These passages are provided with valves which open to allow of the relief of excessive pressure and the escape of water of condensation. There is one claim.—No. 698. January 14th, 1889. 6*d*.

Gas Engines.—*D. B. Peebles, Edinburgh.*—In this improved gas engine the piston rod is dispensed with, and the connecting rod connected direct to a double-acting piston and plunger. In the accompanying illustrations Fig. 1 is a plan, Fig. 2 a sectional elevation of the engine. Figs. 3 and 4 are sections upon the end of a cylinder, showing the valves; Figs. 5, 6, and 7 sections upon details. A is the double-acting piston working in the cylinders B C. I are the valves controlling the admission of the working fluids to the cylinder, the valves being worked by the levers K, which are actuated by cams L upon the shaft M. The shaft M is revolved by a chain N geared to pulleys upon the crank shaft and shaft M. Referring to Fig. 3, it will be seen that three valves are shown; the valve I is for the exhaust, H for admittance of air, J for admitting the explosive mixture of gas and air. The valve J works in conjunction with the gas valve Q, Fig. 4. The gas is supplied by the pipe P, and is admitted by

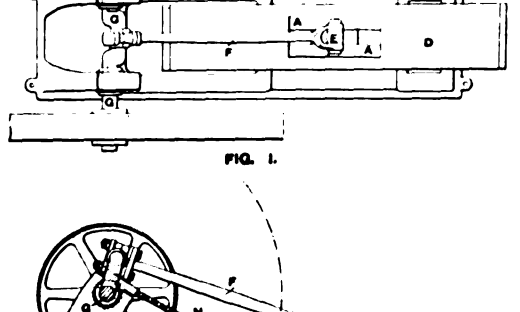

Fig. 1.

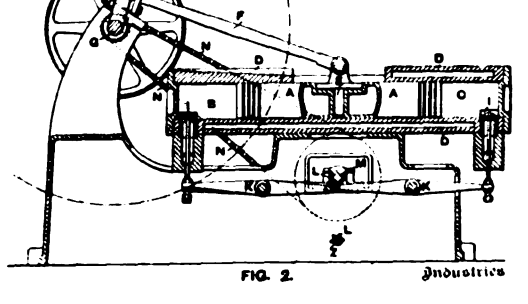

Fig. 2. Industries

the valve Q to the annular space R. The annular space R communicates with the top of the inner chamber T, to which air is admitted from the inlet U. The gas and air are thus mixed, and admitted by the valve J to the cylinder. Another form of valve to replace J is shown in Fig. 6. The gas is there admitted to the annular space W and mixes with the air passing up the space V. Fig. 7 shows a form of valve which may be used to regulate the supply of gas in combination with an ordinary rotary governor. The governor is connected by the lever A^1 to the rod E^1 of the valve F^1. Gas is admitted to the valve by the tube H^1, passing through the valve to the pipe J^1, and from there to the engine. The valve F^1 is constructed with tapering feathers, so that as it is raised more gas is allowed to pass. A gas-tight water joint is constructed by an inverted bell-shaped piece B^1 and tube C^1 in such manner as to cause no resistance to the free action of the

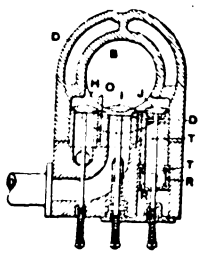

Fig. 3.

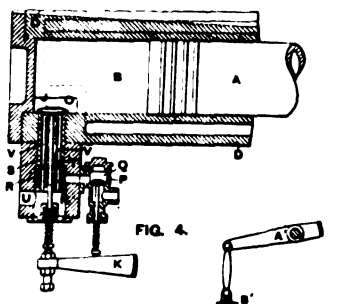

Fig. 4.

Fig. 5.

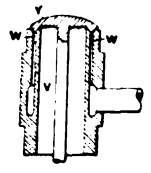

Fig. 6.

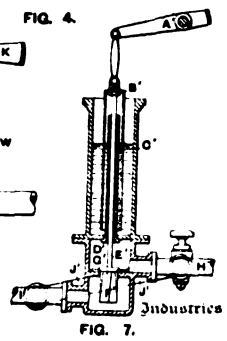

Fig. 7. Industries

governor and valve. The cycle of the engine in each cylinder is as follows:—1, outstroke taking in gas and air; 2, instroke compressing; 3, outstroke exploding; 4, instroke expelling products; 5, outstroke drawing in air to clear cylinder; and 6, instroke expelling clearing air. Claims:—(1) The improved combination of parts forming a double-acting gas motor, with the cycle of operations at each end or cylinder extending over three revolutions of the crank shaft, during one of which revolutions following one during which a charge has been ignited, and the larger part of the used gases expelled, pure or unmixed air is drawn in and expelled preparatorily to the drawing in and compressing of the next explosive charge; (2) in a double-acting gas motor placing the crank shaft in a plane above or out of the plane passing through the axis of the cylinders and connecting the crank to a stud projecting from the plunger or piston piece; (3) the improved combination of parts comprising the valves and the parts or gearing by which they are moved as described; (4) the improved combined air and gas inlet valve apparatus shown in Figs. 3, 4, and 5; (5) the improved combined gas and air inlet valve shown in Fig. 6; (6) the regulating of the supply of gas to a gas motor by means of a rotating governor combined with the valve apparatus shown in Fig 7.—No. 1957. February 4th, 1889. 8*d*.

Recovering Sunken Vessels.—*G. Barnett, Sunderland.*—The inventor employs a number of flexible water and air tight bags, which in their normal or closed condition occupy very little space. These bags in their closed condition are inserted by divers into the various parts of the sunken vessels, or attached to some part of the same, and then inflated by air pumped into them by air-pumps situated upon the vessel from which the operations are being conducted. The volume of air held within the vessel in this manner may be made sufficiently large to raise the vessel to the surface of the water. When the vessel has been raised, the inventor makes use of dished plates of metal, whose edges are covered with india-rubber or some such material, for making a joint with the side of the vessel when the plate is bolted to the vessel to cover the hole or damaged part which has caused the vessel to sink. Claims: (1) In raising sunken vessels and the like, flexible water and air proof bags, in combination with conduit pipes and air or gas compressing apparatus, arranged and operating as described; (2) for temporarily repairing holes or fissures in ships' hull plates, semi-spherical or semi-ovoidal repairing pieces, in combination with bolts, the whole being arranged and secured over the holes or fissures so as to form a water-tight joint round it as and for the purpose described.—No. 19,300. December 2nd, 1889. 6*d*.

Wire Twisting Machine.—*J. Atherton, Liverpool.*—This machine is for rapidly twisting a pair of electrical conductors that have been covered with insulating material. The method pursued is to wind one wire spirally around the other, and to afterwards pass the two over stretching drums to equalise them in length and twist. The illustrations show Fig. 1 an end elevation of the apparatus, Fig. 4 a side elevation, and Figs. 2 and 3 details. In the standards B and C is supported by

Fig. 3.

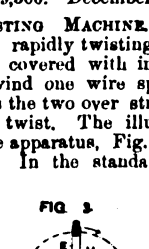

Fig. 2.

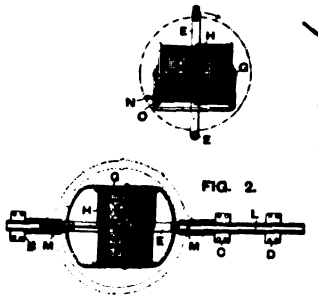

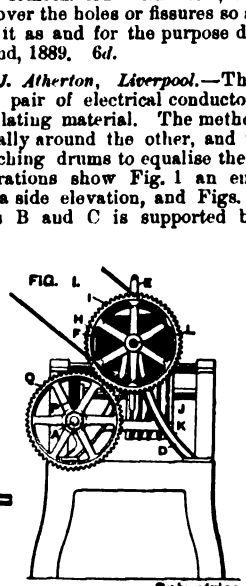

Fig. 1.

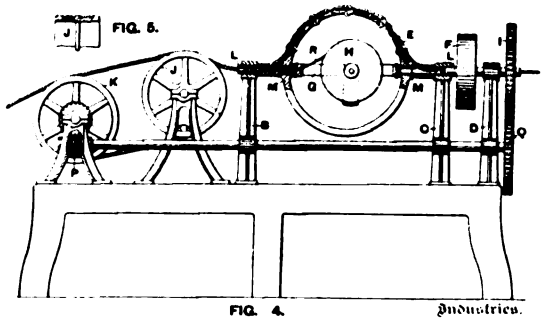
Industries.

its trunnions the frame, or flyer E. In the frame E is supported a racking yoke G by pivots entering the hollow trunnions. An uninterrupted passage is made through the spindle L, the frame E, and its trunnions, to permit one length of wire to be passed through from a bobbin (not shown). Communication is also made between the pivot M of the racking yoke and the trunnion L of the frame E, to allow the wire from the bobbin H to be passed through. The wires are twisted by first drawing them through their respective passages and winding them round the stretching drums J K. The frame E is then revolved by the belt pulley F, and the wire in the frame spirally twisted round the wire from the bobbin H. At the same time the

Fig. 5.



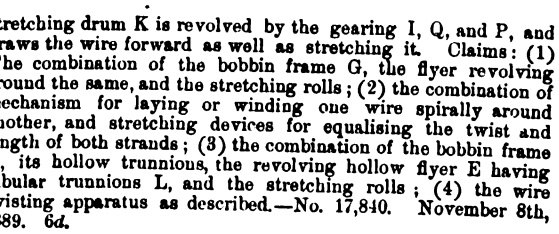


Fig. 4.

Industries.

stretching drum K is revolved by the gearing I, Q, and P, and draws the wire forward as well as stretching it. Claims: (1) The combination of the bobbin frame G, the flyer revolving around the same, and the stretching rolls; (2) the combination of mechanism for laying or winding one wire spirally around another, and stretching devices for equalising the twist and length of both strands; (3) the combination of the bobbin frame G, its hollow trunnions, the revolving hollow flyer E having tubular trunnions L, and the stretching rolls; (4) the wire twisting apparatus as described.—No. 17,840. November 8th, 1889. 6*d*.

Steam Boilers.—*H. M'Coll, Sydenham, Ireland.*—The application of this invention to boilers is to prevent the injurious action due to differences and changes of temperature occurring when water is fed into such boilers in a cold or comparatively cold condition. A feed-water heater, to remove these defects, is constructed according to this invention as follows:—A number of cylindrical shells, of graduated sizes, with end plates or castings, are combined to form a series of annular cylindrical spaces. The number of shells or space may vary, but five is preferably employed. By a connection with the feed pipe at the outer end of the heater the water first enters the central or first space, and on reaching the inner end proceeds through passages in the inner end casting into the third space. The water returns towards the outer end of the third space, and then proceeds by passages in the outer end casting into the fifth or outermost space, going through it to the inner end casting by a passage in which it reaches a delivery pipe. The second and fourth annular cylindrical spaces are open at their ends, and as the apparatus is placed in the steam space of the boiler the

Digitized by Google

steam has free access to the said second and fourth spaces, and to the outside of the fifth space. The delivery pipe dips a short distance below the surface of the water in the boiler. Claim: The improved construction of feed heater for steam boilers, in which a number of cylindrical shells or tubes of graduated sizes are arranged concentrically, and combined with end castings, formed with passages to lead the water through some of the spaces, and to give the steam access to other spaces as and for the purpose described.—No. 2,810. February 18th, 1889. 6*d.*

PETROLEUM ENGINES.—*A. E. Tavernier & L. B. Schlesinger, London.*—The petroleum used is first vapourised in a jacket surrounding the cylinder, for the purposes of depositing impurities before entering the cylinder and to cool the cylinder itself without the employment of water as is usual. Referring to the illustrations, Fig. 1 is a vertical section of the engine or motor; Fig. 2, a plan of the same; Fig. 3, a section upon one end of the cylinder

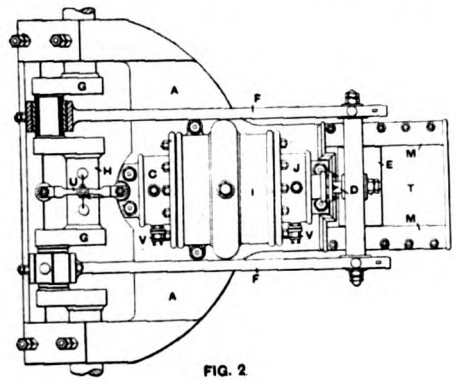

FIG. 2

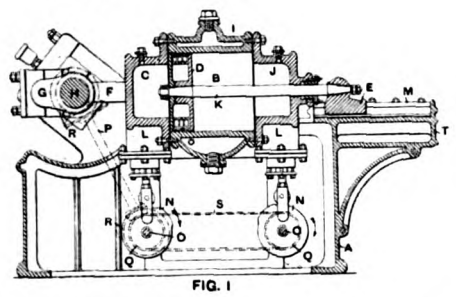

FIG. 1

through the valves; and Figs. 4 to 7, details of the engine. The engine is constructed with a cylinder B having explosive chambers or recesses C J. Its piston D is connected to a crosshead E sliding in the guides M. To the crosshead E are connected the connecting rods F, which are coupled to the cranks G G of the crank shaft H. The valves enclosed in the chambers L are worked by cam discs N, geared to each other by a chain S and to the crank shaft by bevelled gear wheels R and shaft P. The petroleum is pumped by a suitable pump (not shown) to the jacket I surrounding the cylinder. As the petroleum is vapourised, it is conducted to the valve chambers, and admitted to the ends of the cylinder by the valves. Any excess of petroleum vapourised

FIG. 3.

FIG. 4.

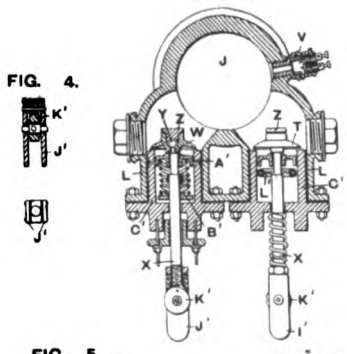

FIG. 5.

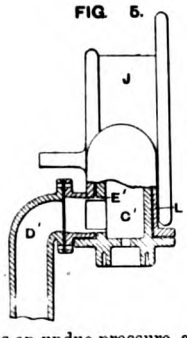

FIG. 6.

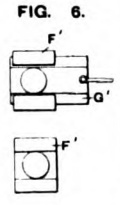

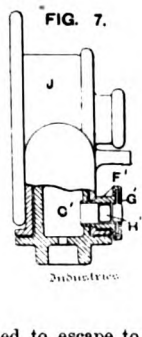

FIG. 7.

causes an undue pressure, and is permitted to escape to a condensing arrangement, and ultimately returned to the supply reservoir. Referring to Fig. 4, T is the valve for admitting the explosive mixture of petroleum vapour and air, and W the valve for exhausting the products of the explosion from the cylinder. The air is admitted to the valve chamber cylinder M by a sliding valve G^1 (see Figs. 6 and 7). The petroleum vapour is admitted to the valve cylinder M by a circular perforated ring L^1 to mix it well with the air. A governor is used to regulate the supply of vapour to the cylinder. The operation of the motor is as follows:—The fly wheel is revolved by hand to operate the feed pump and supply petroleum to the jacket. The first few explosions are caused by admitting a light hydrocarbon to the cylinder from a reservoir situated in the base of the engine. When sufficient explosions have been made to vapourise the petroleum, the petroleum vapour is used, and the connection to the light hydrocarbon reservoir closed. Gas is drawn into the cylinder in the outstroke, compressed in the instroke, and fired. The operation is the same at each end of the cylinder. The mixtures are exploded by electric sparks passing between the points in the case V. Claims: (1) In an engine or motor operated by petroleum or other hydrocarbon vapours a jacket surrounding the power cylinder for containing the petroleum or other hydrocarbon and enabling their vapours to be produced by means of the heat generated by the explosions in the said cylinder; (2) in an engine or motor operated by petroleum or other hydrocarbon vapours the combination with a jacket, such as that described in the preceding claiming clause, of means for preventing the overheating of the power cylinder, such means comprising a valve and condenser, the said valve being adapted to be opened automatically when the pressure of the petroleum or other hydrocarbon vapour rises above a certain degree, to allow a portion of the said vapour to escape, and the condenser serving to condense the said escaped portion of the vapour; (3) the improved engine or motor, substantially as described and illustrated.—No. 1603. January 29th, 1889. 8*d.*

GRINDING MILLS.—*H. Birkbeck, London. (J. Jones & A. J. Jones, Thorold, Canada).*—This invention refers to mills used in grinding wheat, &c. The mill consists essentially of a longitudinally grooved roller held stationary between two revolving rollers. One of the two revolving rollers has longitudinal ratchet-shaped furrows cut round its periphery, whilst the other is grooved similarly to the stationary and central roller. Under the ratchet-shaped furrowed roller is a stationary grooved plate provided to grind any large pieces escaping the first action. In operation, the grain is first admitted between the stationary roller and the ratchet-shaped furrowed one. After passing between these rollers it falls on to a perforated plate, which leads the coarser part of the grain to the surface of the grooved plate, whilst the finest parts in the shape of flour fall through the perforations. The coarser parts, after passing between the grooved surface plate and the ratchet-shaped furrowed roll, fall on to a second perforated plate, and the finer parts are separated from the bran and conveyed to the rest of the flour. The bran is lastly passed between the third roller and the stationary one. Claims: (1) In a grinding mill, a revolving roller having longitudinal ratchet-shaped furrows cut around its surface, for the purpose described; (2) in a grinding mill, a revolving roller having longitudinal ratchet-shaped furrows cut around its surface, in combination with a grooved or corrugated roller for the purpose described; (3) in a grinding mill, a revolving roller having longitudinal ratchet-shaped furrows cut round its surface in combination with a grooved or corrugated roller, and a stationary grooved or corrugated plate, for the purpose described; (4) in a grinding mill, a revolving roller having longitudinal ratchet-shaped furrows cut around its surface, in combination with a grooved or corrugated roller, a stationary grooved or corrugated plate, and a perforated skirt or plate, for the purpose described; (5) in a grinding mill, a revolving roller having longitudinal ratchet-shaped furrows cut around its surface, in combination with a grooved or corrugated roller, a stationary grooved or corrugated plate, a perforated skirt, or plate, and a second perforated plate with spout for the purpose described; (6) in a grinding mill, a stationary grooved or corrugated roller, in combination with a revolving roller having longitudinal ratchet-shaped furrows cut in its surface, and the revolving roller having longitudinal grooves or corrugations formed on its surface for the purpose described.—No. 18816. November 23rd, 1889.

ELECTRICITY.

REGULATOR.—*Siemens Brothers & Co., Limited, London. (A. M. Taylor, Baroda, India).*—One of the leads for the secondary current from the transformer, instead of going directly to the lamps or other objects which it works, passes on its way through the coils of a solenoid, the core of which is one of the limbs of a horseshoe or U-shaped piece of soft iron. The other limb is also the core of another solenoid, having a greater number of convolutions than the former. The latter solenoid is in a shunt circuit connecting the leads for the secondary current at points before and after it passes through the lamps or other objects worked by the current. The two limbs constituting the cores above mentioned, and their U-connection, are suspended by an adjustable spring, and are free to move up or down within the two solenoids, presenting their ends towards a stationary bar of iron. The regulator operates in the following manner:—When the expenditure of electricity is lessened, as for instance by extinguishing a number of lamps, more of the secondary current passes through the shunt coil, exciting its core magnetically, so that the cores are attracted towards the stationary iron bar and move towards it in opposition to the spring. This approach of the other core induces in its coil, which is in the main secondary circuit, a back electromotive force, reducing that of the current proceeding to the lamps. Claim: A regulator for transformed electric currents, consisting of a two-limbed solenoid, made in horseshoe form and suspended by an adjustable spring, with the ends of its cores presented towards a stationary armature, the one core having its coil in the main secondary circuit and the other core having its coil of a greater number of convolutions in a long shunt from the secondary circuit, as described.—No. 4192. March 9th, 1889. 6*d.*

INCANDESCENT ELECTRIC LAMPS.—*R. A. Sloan, Liverpool. (G. W. Wilson, Boston, U.S.A., & C. H. Brown, Newton Highlands, U.S.A.)*—This invention is an improvement in incandescent lamps, and its object is to provide a reflecting surface between the limbs of the filament to break up and distribute the light in the most effective manner, and at the same time to prevent short-circuiting or bombardment between the filament limbs, so destructive to the material of the filament. The reflector is made of a transparent non-conducting material such as glass, and is made hollow, whereby the rays of light are not only reflected from the convex surface of the reflector, but are also reflected from the concave interior surface. The reflector may be coloured to give the reflected light a distinctive character, and the hollow of the reflector might be filled with crystals such as iodine of lead. *Claims:* (1) *In combination* with an incandescent electric lamp a non-conducting transparent or coloured reflector in tubular form interposed between the limbs of the filament; (2) in combination with an incandescent electric lamp a non-conducting tubular reflector having a filling of crystals as described.—No. 18004. November 12th, 1889. 6*d.*

ELECTRIC BELL.—*F. H. Berry, London.*—A single magnetic coi is supported by a frame upon a base with its axis parallel to the surface of the base. Parallel to the axis of the coil and upon one side of it is a hammer with an adjustable spring contact working in the manner usual in electric bells. The whole is covered by the bell or gong, which is supported at its centre by the framing supporting the magnetic coil and hammer. The hammer is made to either strike against the inner surface of the bell or against a projection proceeding from it. Four claims are made.—No. 3580. February 28th, 1889. 6*d.*

CHEMISTRY.

COLOURING MATTERS.—*B. Willcox, London. (Farbenfabriken v. F. Bayer & Co., Elberfeld).*—The inventors have discovered that nigrosine, aniline black and saffranine can be converted into dyestuffs which are soluble in water by melting them together with para-phenylene-diamine. By means of this process dyestuffs are obtained which are readily soluble in water. About one part of nigrosine is heated to from about 170° to 190° C., with two parts of para-phenylene-diamine until the melt dissolves readily and completely with a clear colour in dilute hydrochloric acid. After cooling, the melt is dissolved in dilute hydrochloric acid and the dyestuff is salted out from the filtrate. The proportions may be varied and only slight differences in the colour result. Dyestuffs dyeing a deep blue-black are obtained by substituting aniline black or saffranine for the nigrosine in this example. When azo-benzene is melted with para-phenylene-diamine in the presence of a certain quantity of ammonium chloride at a temperature of from about 220° to 240° C., a dyestuff soluble in water is obtained which possesses very strong dyeing powers. Claims: (1) The process for the manufacture of indulines soluble in water by melting together the dyestuffs known in commerce under the names of nigrosines, aniline black and saffranine, and the azo compounds—viz., azo-benzene, azotoluene, benzeneazotoluene, azooxybenzene, azocxytoluene, hydrazobenzene, or hydrazotoluene, or mixtures of them with meta or para-phenylenediamine, or toluylenediamine in the presence of ammonium chloride at a temperature of 100° to 250° centigrade; (2) the process for the manufacture of indulines soluble in water (which is an oxidising process) by melting together meta or para-phenylene-diamine with weak oxidising agents—viz., quinone, chloranil, dichlor-naphtho, quinone-naphtho-quinone, or chlorimide, with or without the presence of benzoic or oxalic acid, and of a condensing agent such as chloride of zinc and chloride of calcium at a temperature of 100° to 200° centigrade; (3) the process for the manufacture of indulines soluble in water by melting together nitro-aniline (nitraniline), nitro-toluidine, or mixtures of them with hydrochloric acid salts of primary amines—viz, aniline, toluidine, xylidine or secondary and tertiary amines—viz., monomethyl-, ethyl-, benzyl-anilines; dimethyl-, diethyl-, methylbenzyl, ethyl benzyl anilines, or mixtures of them with or without the employment of some chloride of iron, benzoic acid, oxalic acid, or ammonium chloride, or both, and a condensing agent—viz., chloride of zinc or chloride of calcium, at a temperature of 100° to 250° centigrade; (4) as new articles of manufacture the products claimed in each of the foregoing claims.—No. 3529. February 27th, 1889. 6*d.*

WASHING ORES.—*G. C. Dymond, Liverpool. (O. Bilharz, Freiberg, Germany).*—In the ordinary annular ore sieving machines considerable time is lost in the frequent raising and lowering of the circular sieve plate upon which the ore is placed. To obviate this loss of time, the sieve plate is suspended from cross-bars resting upon the upper edges of the sieve box. The sieve plate is suspended from these bars by bolts fastened to bars beneath the sieve. The tops of the bolts pass through the cross-bars and are held in any desired position by thumb-screws upon their screwed part. Claim: In circular apparatus for washing, sieving, or separating ores, the application of cross-pieces connected by bolts to bars below the jigger sieve, whereby the sieve may be raised or lowered at any moment without interrupting the course of the machine as described.—No. 65. January 2nd, 1889. 6*d.*

PARA-AMIDO-PHENOL ETHERS.—*B. Wilcox, London. (Farbenfabriken v. F. Bayer & Co., Elberfeld).*—The manufacture of para-amido-phenol ethers is attended with considerable difficulty in practice, this being especially the case in the manufacture of the ethyl ether or the monacetyl combination of para-phenetidine. The nitriting of the phenol proceeds in such a manner that only about 50 per cent. of the para combination is obtained. The inventors have discovered that by conducting the process as afterwards described, phenol can be smoothly and quantitatively converted into the para-amido-phenol ether, without the formation of any bye-products. Para-amido-phenol ether or phenetidine is converted in an acid solution with sodium nitrite into its diazo compound, and the latter is caused to react on phenol in the usual manner. The resulting yellow dyestuff is converted into the para-amido-azo-phenol ether with alkyl halogens and splits up into two molecules of para-phenetidine by the reduction of this azo substance. Claims: Manufacturing para-amido-phenol-methyl or ethyl or amyl ethers by decomposing para-phenol methyl ether—azo-phenol methyl ether, or para-phenol ethyl ether—azo-phenol-ethyl ether or para-phenol-amyl ether—azo-phenol-amyl ether into two molecules of para-amido-phenol methyl or ethyl or amyl ethers by reduction substantially as described.—No. 1771. January 31st, 1889. 6*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

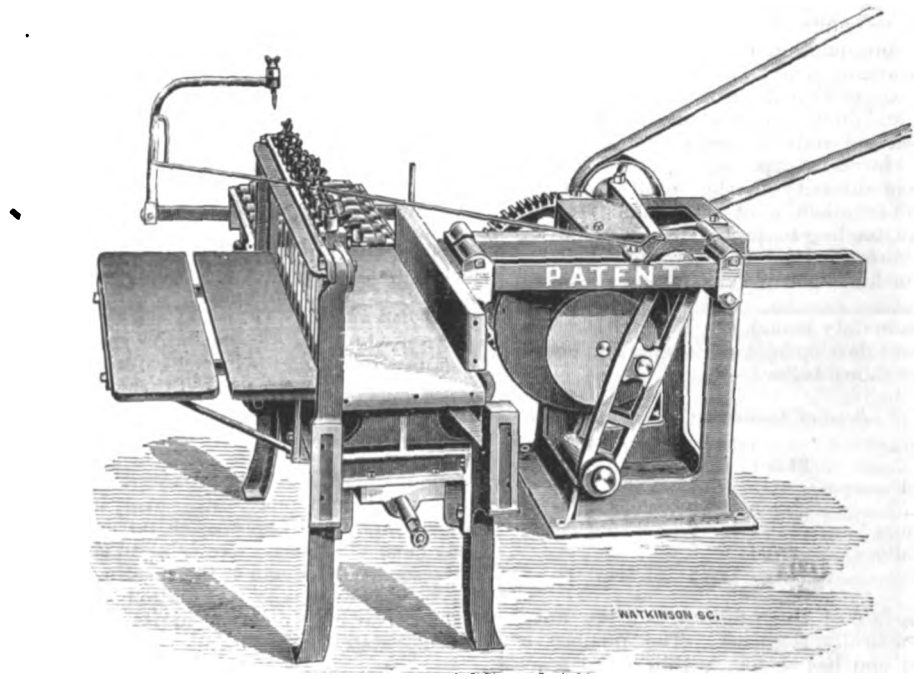
POWER PUSHER FOR BRICK-MAKING MACHINES.

Messrs. Bennett & Sayer, engineers, Derby, have recently brought out an improved power pusher to be attached to their brick-cutting table. The power which is required is comparatively small, and the work is done much more steadily and cleanly than by hand. It can be fitted with the greatest ease to an ordinary hand table, and the cost of labour is thus reduced. A large number of these pushers are already in use, and we understand that they are giving satisfaction.

THE RECENT GROWTH OF TECHNICAL SOCIETIES.

I.

It is necessary, in times of progress like the present, to specialise alike in academic studies and in actual practice. The days have gone by when any one society could take up all branches of study claiming to have a scientific character. The Royal Society, the British Association, and the Institution of Civil Engineers were, within the memory of men still active, deemed to be almost sufficient to cover the whole field—the first-named society taking up pure science, the second pure and applied together, and the third applied science alone. These were aided and abetted, sometimes on the one side and sometimes on the other, by the Royal Institution, which was founded in 1799, "to teach the application of science to the useful purposes of life," and sometimes by the Society of Arts, which was founded in 1754, "for the encouragement of arts, manufactures, and commerce," and which has for many years been an *omnium gatherum* for all sorts of papers and discussions that were not sufficiently special to claim consideration elsewhere. These societies, although still retaining the lead which their earlier establishment enabled them to acquire, have been supplemented by an enormous number of scientific or philosophical bodies of a more or less special or local character. Every science has now its society. Every important science has a "local habitation and a name," not in the metropolis alone, but in each of the leading towns throughout the country. Literary and philosophical institutes, naturalist societies, natural science societies, archæological societies, polytechnic societies, field clubs, and similar bodies exist on every hand. And just as a man's social station receives a sort of stamp from the club, or clubs, of which he is a member, so a man is now-a-days known by the scientific bodies to which he belongs. Many men of science belong to so numerous an array of societies that their annual subscriptions amount to a good round sum, and have become a really onerous charge upon limited incomes. There are, however, certain societies that must be cultivated *nolens volens*. No man who wished to be regarded as a distinguished scientific authority could afford to remain outside the Royal Society, the fellowship of which is the blue riband of science, and is increasingly difficult to obtain. No civil engineer who desired to take high rank in his profession could well afford, unless, indeed, he had already made his name and his "pile," to be a stranger to the Institution of Civil Engineers. Mechanical engineers, naval architects, surveyors, electricians, chemists, iron and steel manufacturers, actuaries and others, find it necessary to join the societies established for their special interests, if they are to be in their own little world, and conversant with its affairs. The "Proceedings" or "transactions" of these several societies are annual text-books of the greatest possible value to the specialist. Their value, indeed, can only be adequately appreciated by those who are old enough to remember when no such professional *vade-mecum* was accessible, and when the engineer, the architect, or any other specialist had generally to evolve his plans by a slow and laborious process from costly experience or an internal consciousness that could not always be depended upon. The extent of the publication of the "Proceedings" of such societies is now quite portentous. Every year the learned societies of the United Kingdom shed abroad a mass of printed matter that would appal anyone who might be called upon to inquire into its extent and character. Some societies, indeed, produce several volumes annually, such as the Institution of Civil Engineers and the Chemical Society. Others, like the Society of Arts, have sufficient pabulum to run a weekly or a monthly "Journal." Others, again, publish quarterly, while still others issue half-yearly or annual volumes. But the tendency is to greatly increase this enormous mass of printed matter, and if the same rate of growth is maintained that we have witnessed during the last twenty years, we may almost literally fulfil the Scriptural hypothesis that "the world itself could not contain the books that shall be written."



There is, as might naturally be expected, a considerable amount of competition among the various scientific societies, both for members and for papers, if they are of the right sort. This, of course, does not apply to the Royal Society, which has its number fixed by statute, and which has always more candidates and papers than it can deal with. But it is more or less true of all the others. There are many cases in which the membership and the special character of one society will overlap with another, or perhaps several others. In such cases the course that appears to commend itself, as a rule, is to join each of the competing societies. Thus, for example, the Chemical Society and the Society of Chemical Industry have largely kindred aims and common grounds, and the same membership. So with the Institutions of Civil Engineers, Mechanical Engineers, and Naval Architects, and, though perhaps to a less extent, the Iron and Steel Institute. So also with the various Institutes of Mining Engineers and the Institution of Mechanical Engineers. It often happens, accordingly, that papers are read before one society that appear on the face of them to be better adapted for, and more special to, the "Proceedings" of another. As an example, all appears to be fish that comes to the net of the Institution of Civil Engineers—which claims to represent every branch of applied science, although perhaps with doubtful propriety—of the British Association, and of the Society of Arts. The scope and range of these bodies give them the means and the opportunity to command a greater variety in their "Proceedings" than would be proper in, say, a society of electricians or a mining institute. This creates a wholesome rivalry, which is not without real gain to the institutions themselves and to the cause of science generally. So, again, with the information supplied by the various societies at home as to the "proceedings" of kindred and cognate learned societies abroad. Some of the principal scientific bodies have made a special feature in their "Proceedings" of presenting "Abstracts," which usually contain the pith of papers read before foreign bodies, or published in foreign periodicals. This work is now thoroughly well done for the sciences of chemistry, metallurgy, and civil engineering, as well as, though perhaps to a more limited extent, for mining and electricity. The learned societies have in this respect taken up, and discharged with much greater efficiency, the work that was formerly done to a greater or less extent by the old-fashioned book clubs.

In spite, however, of the conspicuous importance which has been attained alike in science and in society, by the so-called learned societies, their affairs are seldom obtruded upon public notice, except through their work. The public has hardly stopped to realise that these bodies have become a great influence in the land—great for the diffusion of arts, of manufactures, of material power, and of general intelligence. This influence has been greatly accentuated during the last few years, which, however, is only another way of saying that the progress of applied and pure science during that period has been more remarkable than usual. As an example the Institution of Civil Engineers may be referred to. That society twenty years ago had a membership of only 2,234, whereas up to the 22nd ult. its membership was 4,726; the property of the Institution, exclusive of the valuable library, having within the same period increased from a few thousands to over a hundred thousand sterling. Formerly, scientific bodies had to lay their heads where they could, and commonly they found very cold quarters unless they happened to get under the sheltering wing of a beneficent patron. Now they have their local habitations in palatial mansions, the home of pure science being Burlington House, and the home of the Civil Engineers being little short of magnificent, while the Society of Arts, the Institution of Mechanical Engineers, the Surveyors' Institute, and other bodies have each premises worthy of their several exalted stations. One of the inevitable results that have attended the growth of scientific sociology within the realm has been the accumulation of considerable wealth by the leading bodies, and the hope of accumulations on the part of others. Although some societies still accept Government aid, such as the Royal Society and the Institution of Naval Architects, science, on the whole, is fairly self-supporting, and does not give the State much trouble.

It is not without interest to take some notice of the character of the investments that appear to be preferred by the administrators of our scientific societies. Railway securities are much more in vogue than any other. The Institution of Civil Engineers, for example, have invested in railways some £29,000. These are exclusively British lines. They have also gone in for "the sweet simplicity of Three per Cents.," now reduced by Mr. Goschen's conversion scheme to 2¾ per cent., to the extent of £6,000. These sums are irrespective of the trust funds placed at the disposal of the Institution for investment by Telford, Manby, Miller, and Howard, most of which have been invested in Consols. The Institution of Civil Engineers have, however, laid out the greater part of their surpluses in the acquisition of real estate, the freeholds of 24, 25, and 26, Great George Street, having been acquired by them, so that they are their own landlords. The value of this investment, which can hardly fail to improve, is returned at £40,000. The Institution of Mechanical Engineers has limited its investments to the debenture stock of British railways, and of the Aire and Calder Navigation, but they have besides, like the Institution of Civil Engineers, a substantial interest in the firm of Sir J. Whitworth & Company, acquired by bequest. The market value of the investments of the Institution of Civil Engineers at the end of March last was £98,042 13s. 10d.; while that of the estate of the Institution of Mechanical Engineers was £21,900, the two

POWER PUSHER FOR BRICK-MAKING MACHINES.

Digitized by Google

societies having thus a total reserve of £119,942 13s. 10d. Compared with these two most of the other scientific societies are comparatively poor—first, because their membership is generally less; secondly, because their entrance fees and annual subscriptions are lower; and, thirdly, because their outlay is relatively higher. Civil engineering, as defined by the Council of the Institution, covers a very wide range, so that every branch of applied science, whether rightly or wrongly, is embraced within its pale, while mechanical engineering, if it has not quite so wide a scope, has, at any rate, affinities with every trade and industry that uses or requires mechanical aids.

There is a fair presumption that the affairs of our scientific societies are, in general, well administered—in the first place, because they have usually capable permanent officers; and in the next place, because those officers are assisted and controlled by a council of good social position and business experience. There is, however, a remarkable diversity in the results that are brought out by an examination of their annual reports and balance-sheets, tending to prove that each has its own way of administering its own affairs, and does not slavishly imitate or lean upon the example of its neighbours.

Taking, first, as in duty bound, the Royal Society, we find that the recent development of income and expenditure has been as shown below:—

Items of Income.

	1878.	1888.
Subscriptions	£1,001 0 0	£1,036 0 0
Entrance fees and compositions	250 0 0	318 0 0
Sale of "Proceedings"	871 12 7	594 6 5
Bequests and donations	2,700 0 0	—
Dividends, rents, &c.	2,796 18 8	3,466 17 3

It looks, on the face of these figures, as if the Royal Society were practically stagnant. The number of fellows is limited, and has seldom, within recent years, exceeded 525. It is evident also that the "Proceedings" are less sought after than they were, their sale having apparently been reduced by nearly £300 during the ten years. It is a question with many men of eminence whether this Society is quite entitled to the place it occupies as the foremost body of its kind in Anglo-Saxondom. It is certainly hardly liberal enough for the present age, following the devices of antiquity rather than advancing to meet the new developments of to-day, and excluding from its pale many men who would be an honour to any body. The Society has a library of 40,000 to 45,000 volumes, and it awards five medals, four annually and the fifth biennially, which have been competed for by the most illustrious men of science for generations.

It is difficult to discover exactly what is the value of the property owned by the Royal Society. They have real estates at Mablethorpe, Lincolnshire; at Acton, Middlesex; at Lewes, Sussex; and at Lambeth Hill. They have, under the Stevenson bequest, one fourth of an annual interest on £85,336 Government annuities and bank stock, they have over £20,000 in reduced 3 per cent. annuities, £15,000 on mortgage loan at 4 per cent., over £16,588 in consolidated bank annuities, £10,000 in Italian irrigation bonds, £6,000 in London and North-Western 4 per cent. debentures, and investments in British and Indian railways. In 1878 these several properties were worth well on to £100,000, and produced about £2,797 as ordinary, and a much larger amount as trust fund income. In 1888 the trust funds of the Society brought in an income of £16,147, including sales of stocks, of which £15,771 was expended, £7,990 being spent on scientific relief, grants, and investments, and £6,346 on donations, grants, &c. Under the Gassiot trust an annual payment of about £500 is made to the Kew Committee. At the end of 1888 the Society had a total income from ordinary investments and trust funds of £19,612, which would represent an investment of nearly £400,000 at 5 per cent. interest. A large part of this income was, however, realised from sales of stock, so that it is difficult to say what the net annual income really is.

The outlay of the Royal Society has been as under:—

Items of Expenditure.

	1878.	1888.
Salaries and wages	£1,146 3 0	£1,675 3 8
Printing and illustrations	2,144 1 0	2,593 10 8
Soirée expenses	77 19 6	109 1 4
General office expenses, &c.	392 15 3	861 6 2½
Purchase of land	228 0 0	—
Donation and law charges	6 15 10	96 14 8

The expenditure for the year 1888 includes an item of £79 for the installation of the electric light into the Society's rooms. The expenditure has, it will be seen, advanced to a larger extent than the income, but a society possessed of such wealth and occupying so high a pedestal may well be excused if it is independent of ordinary considerations of finance. This, at any rate, appears to be the view of its chief administrators, who have distinguished themselves by reducing the number of fellows from 798 in 1850 to 597 in 1870, and to about 500 at the present time.

The "Parliament of Science," as it has been termed, the British Association for the Advancement of Science, has made steady and consistent progress of late years. The income as between 1878 and 1888 has varied as shown in the following table:—

Items of Income.

	1887.	1888.
Subscriptions and compositions, including ladies' tickets	£2,760 0 0	£4,650 0 0
Sales of "Proceedings"	110 14 0	190 5 5
Dividends	249 13 9	295 8 2
Other items	42 15 1	78 10 6
Total	£3,163 4 10	£5,214 4 1

Some years ago, the question was seriously debated whether the functions of the British Association had not ceased. It was contended that, as every branch of science had now its own special society or institute, there was no need for a general scientific society, intended "to promote science and direct general attention to scientific matters," but it has been found that even if this function is not so important as it was, there is another expressed in the constitution—that of "faciliting intercourse among scientific men"—which is greatly appreciated. The annual meetings of the Association are the agreeable rendezvous of men representing every branch of scientific inquiry; and if it happens, as no doubt it does, that many members attach more value to the recreative than to the scientific aspects of the meetings, no one is hurt thereby. This pic-nic Association tends, however, to become increasingly lavish in its expenditure, as the following statement shows:—

Items of Expenditure.

	1878.	1888
Salaries	£495 0 0	£538 15 0
Rent	104 5 0	117 0 0
Printing	585 6 3	2,198 10 0
Meeting expenses	1,231 16 8	314 18 2
Grants	1,080 11 11	1 511 0 5

The accounts are not presented in quite the same form for these two years, so that an exact comparison of items is impossible. In 1878, for example, the item of expenditure on the Dublin meeting included printing, binding, &c., besides the Proceedings or Report; whereas for 1888 the printing is quite a distinct item. All that is possible is to group the two items of meetings and printing, when the totals come to £1,817 2s. 11d. for 1878 and to £2,513 8s. 2d. for 1888. It appears, however, that part of this difference is accounted for by the payment of accounts that should have been paid and included in the balance-sheet for 1887. The expenditure, like the income, varies greatly from year to year, according to the place and character of the meetings. The actual number of members on the books is stated to be about 4,000, but the income fluctuates between £1,300 and £3,200, according to the attendances.

The Society of Arts is one of the largest miscellaneous societies that does not cultivate any art or science in particular, although having done, and still doing, a useful work. Its income has been as follows:—

Items of Income.

	1878.	1888
Subscriptions	£6,537 6 0	£6,296 8 0
Sales of "Journal"	205 16 10	143 10 0
Advertisements	1,603 4 4	923 1 9
Dividends, rents, and interest	656 0 6	965 5

The Society of Arts has a special income from examination fees, which, in 1888, amounted to £311 13s. It has also smaller items of income from fees for the use of the meeting room, and from the sale of special reports, such as that of the Canal Conference held last year. It is not satisfactory to find that the income of this useful body has fallen off; and the fact is, perhaps, a sufficient proof that any body that wishes to prosper nowadays must be distinctly special, and must both enlist the sympathies of, and show itself particularly serviceable to, a particular art or craft. The expenditure of the Society of Arts has varied over the same period as follows:—

Items of Expenditure.

	1878.	1888.
Salaries, &c.	£1,672 2 1	£2,046 2 11
Rent, taxes, and repairs	1,114 9 7	743 16 6
"Journal"	2,558 15 2	2,247 7 8
Conversazione	218 7 10	407 5 6
Advertisements	832 19 8	438 18 4

The Society of Arts' accounts show that while in 1878 they received a gross income of £1,603 4s. 4d. from advertisements in the "Journal," the expenditure on advertisements, presumably in securing this income, seeing that ordinary advertising is provided for under the item of office expenses, and absorbed a further £44 13s. 6d., amounted to £832 19s. 8d. This is, of course, a very large item to be expended for such a purpose, and if it was not so expended the accounts are not so clear as they should be. Besides the items given above the Society has incurred a large expenditure for medals, lectures, and other purposes, and in 1888 they incurred an outlay of £683 in a competition for prime motors.

(*To be continued.*)

TRAINING FOR TRADES AND CRAFTS.

By Henry Dyer, C.E., M.A.

I.

The development of machinery has been the direct cause of the demand for improved technical, and for a change in general, education, about which we have heard so much during recent years. The immense number and variety of our manufactures have brought about a complete social and economic revolution, which has entirely altered the conditions under which trades and crafts are learned. In the old days, not only was the master himself a craftsman, but he took a personal interest in the education of his apprentices, who were often members of his own household, and the conditions of admission to the trades-guilds were such as to ensure that proper use had been made of the advantages they had had by all who wished to become members. Thus a high degree of manual skill was generally attained, and the secrets of the trades, which, of course, were simply the concentrated results of past experience, and what we now generally call "theory," were handed down from generation to generation.

All this was changed, however, with changing social conditions. The working master became a capitalist and a non-worker, who had neither the time, inclination, nor ability to instruct his apprentices, who were for the most part allowed to pick up their trade as best they could, while the division of labour made it impossible for them, unless in a few favoured cases, to have any experience except in a very limited part of the trade. On the other hand, the trades unions have confined their attention almost entirely to the question of wages, and have made no attempt to test the ability of their members either in the theory or practice of their work. The fact is, we have all, both employers and employed, trusted too much to our immense natural resources and our accumulated experience, while on the Continent, and even in a new country like America, the changed conditions of the times have been recognised, and attempts have been made to methodise the training which is necessary in the different departments of trade, and apprenticeship and trades schools have become common. The consequence is, that we do not now hold the pre-eminent position we did thirty years ago. It is not necessary to enter into either a description or criticism of these schools, as the opinion has been expressed by all concerned in this country—at least by all whose opinions are worth anything—that the manufactory or workshop must remain the place where the chief part of the practical training in trades and crafts is to be given. At the same time, it is admitted that the changed conditions of production render necessary a specialised training which cannot be wholly attained in the workshop.

To prevent misunderstanding, and to keep the discussion within reasonable limits, it will be convenient if we explain what we mean by the terms *apprenticeship* and *technical education*. Apprenticeship is the process of training which is undergone by anyone who wishes to learn the practice of any craft, art, trade, or profession. Technical education, on the other hand, is a term of more limited meaning, and implies a general training in the principles of applied science and instruction in the application of these to special trades or professions. Of course, if we took the term simply in its etymological sense, it would go further than this, and include the practice of the work, but, as already explained, in this country at least, the technical school is not intended to take the place of the workshop, but only to supplement its teaching. In the workshop the apprentice learns methods, and in the technical school the corresponding reasons, that is to say, in the former he is chiefly taught to imitate, whereas in the latter he is trained to think. It is too often assumed, however, that men are best taught to think by attendance at lectures, in which information is pumped on them by an eloquent enthusiast, or packed into them by a systematic "Dryasdust" from the resources of his own extensive reading, or, as is too often the case nowadays, from a well-crammed text-book, which has been written after a careful study of the

Digitized by Google

idiosyncrasies of the examiner, on whose decisions the fates of the students and the teachers largely depend. Pumping and cramming are both useless in so far as education is concerned, and very often produce hatred and despair in the students, and inevitably lower the ideal of education.

In a well-organised technical school, therefore, the education is made real by giving the students an intellectual interest in their work. Lectures, drawing office, and laboratory work all lead to this end, and are treated as forming parts of the same class. In the lecture room principles are explained and illustrations given; in the drawing office results are delineated graphically; while in the laboratory experiments are made to confirm known principles or to ascertain new laws and properties of materials and machines. It must be distinctly understood that a laboratory is *not* a workshop. In a workshop the object is to attain manual dexterity, and the operations are repeated under the same conditions; in a laboratory the conditions are varied in nearly every experiment, so that the student may obtain practical knowledge and be prepared to act under any emergency. Work in a laboratory pre-supposes a certain amount of manual training. In our present disorganised system it may be necessary, occasionally, to give a little of this in the laboratory, but the place for it is either in the elementary or the secondary school, both of which should train the eye and the hand at least as much as they cram the brain. Drawing and manual training work of various kinds would serve to make the instruction real, and could be done without adding very much to the expense of the school, but it pre-supposes teachers who are real teachers, and who have liberty to develop their work in a manner suitable to the requirements of the scholars.

It must be admitted that the present systems of elementary education and of apprenticeship are not at all designed to the best advantage of either the masters or the apprentices. The mechanical mental drill of the school room has not been found to produce intelligent and active-minded boys, and is in danger of leading to the substitution of equally mechanical manual drill—in fact, into the conversion of the elementary school room into a toy workshop, and of the secondary school into an establishment for the training of apprentices, as is now being done to a considerable extent on the Continent and in America. Such trades or craft schools have their uses, especially in the smaller and more artistic classes of work, but if the employers of labour neglect their evident duty in arranging for the training of a due proportion of apprentices, and so render such schools necessary, it is their business to support them, and not expect that to be undertaken at the public expense. The cry for improved technical education has met with a feeble response on the part of the workmen, as they think, and, in fact, as they say plainly, that the whole movement is intended for the benefit of the employers, and to relieve them of their proper duties; and it must be admitted that to a large extent they are right. If employers of labour had continued to take even a small personal interest in the education and welfare of their apprentices, we would not have heard much of the cry for improved technical education. This could have been done at a comparatively small expense, and at very little trouble. In some of the more artistic trades, as already explained, special schools, or classes in existing schools, might be necessary, especially where the work was subdivided to a very large extent, but for the most part the apprentices could get all the theory they want in the ordinary classes for science and art, while the workshop or manufactory would continue to afford opportunities for obtaining the necessary practical skill. Success in any trade or profession does not depend so much on the amount of information which may have been crammed into the learner's head as is often supposed. Lord Armstrong recently pointed out that it depends incomparably more upon his capacities for useful action than upon his acquirements in knowledge, and he therefore urged that the education of the young should be directed to the development of faculties and valuable qualities, rather than the acquisition of knowledge, which may be deferred to more mature age. British engineers and British workmen generally have been able to hold, what their Continental neighbours consider more than their own, chiefly on account of their good practical training and sound common sense, two qualities which are not always possessed in any great degree by those who have spent an undue proportion of their time at schools or colleges. These may make arrangements for more systematic instruction in the different parts of a trade, but they cannot impart the true spirit of the successful manufacturer, which is only to be got in the atmosphere of the actual workshop. Therefore any system of training which keeps the young men or women from actual contact with the conditions of everyday work should not receive any encouragement, not only on that account, but also because it relieves employers from what ought to be part of their recognised duties, and tends to perpetuate a stereotyped form of instruction. When the school is entirely separated from the workshop the teaching is sure to become antiquated and deadened by official routine.

We sometimes hear candidates for Parliamentary honours saying that they are in favour of education being free, from the elementary school to the university and the technical college, and every opportunity being given to all who had the necessary ability to take up any department for which they were inclined. Whatever arguments there may be in favour of elementary education, in so far as it is compulsory, being relieved from the direct payment of fees, so that each one in the land may have an opportunity of making something like a fair start (a matter which is practically settled in the affirmative in so far as Scotland is concerned), and however advisable it is to arrange an educational ladder which will lead from the lowest class in a Board school to the highest class in a university, it must never be forgotten that the overcoming of difficulties is the most useful part of a man's education, and nothing should be done which would destroy his self-reliance and determination. It is well known that when men fail in life it is generally not so much from want of knowledge as from want of natural capacity, energy, and perseverance. Universal free education is therefore only an ideal which should be realised when we have a more perfect state of society.

(To be continued.)

NOTES ON PATENTS.

III.

TRADE SECRETS.

It often becomes a matter of some importance to an inventor whether he should keep an invention to himself or obtain protection by letters patent. The question is frequently asked, Is it worth while to patent an invention? This resolves itself purely into a matter of profit and loss. A manufacturer, however, has frequently to consider whether he cannot get more out of his invention by keeping it to himself. One course or the other must be adopted at once, as the profitable use of an invention will preclude him afterwards from obtaining valid Letters Patent. It is true that the product does not necessarily reveal the machine or the process by which it was made, but the rule is founded on public policy. An inventor in England is not allowed to practise his invention for, say, four or five years, and then, finding he can keep its secret no longer, apply for Letters Patent.

There are some inventions which, from their very nature, it would be preposterous to treat by way of trade secret. There are a few inventions consisting of processes which are capable of being so dealt with. Even in such cases, if an inventor wants to do anything beyond manufacturing in his own works he must patent. If, for instance, he wishes to license, or sell, either at home or abroad, he must patent. It is evident that, for all practical purposes, a trade secret is not a negotiable property. The great advantage of a trade secret is that the owner has the most perfect monopoly, *while it lasts*. If Letters Patent are applied for, rival manufacturers are at once informed of the new departure. The inventor may have to protect himself by expensive litigation. One advantage of a trade secret is that there is no fear of other persons obtaining a compulsory licence of the invention. There is always present the disadvantage consisting in the risk of disclosure, but there is the possibility of a longer monopoly than fourteen years, which is the limit of Letters Patent. There are many cases in which inventions have been worked as trade secrets for years. In more than one case which has come to our notice an invention has been lost on the death of a partner or foreman who knew it. The great practical objection to a trade secret is the difficulty of keeping it secret. There have been successful instances where it has been done in mechanical cases by dividing the work amongst a variety of hands, so that one hand only knows the details, and not the entire work. In the glass and china trade there are instances of trade secrets having been kept for many years. In these cases the invention has been in the knowledge of the principal, and perhaps his manager. In the manufacture of alloys trade secrets have been kept for years.

There are some cases where, to ensure the secrecy of processes, operatives have been chosen for their dulness or want of perception; chemical substances have been disguised and misnamed; the dials of pressure gauges have been altered, and the scales of thermometers have been graduated on a false basis. These expedients have, to a certain extent, proved successful; but where, however, the invention is known to the operatives, the risk of its disclosure is very great. The most effectual means of preventing such disclosure is to retain a part of the wages. It is the custom of one large firm, not only to divide the work, but to retain, in addition, a part of the pay (known as "bonus pay") for three years. This has the effect of keeping the men in the master's employ; and the pay is forfeited if they enter the service of a rival manufacturer. Where this system of deferred pay is in force, the men, on entering, are actually sworn in to keep the secrets of the business. The retention of a part of the pay is a most powerful weapon. Sometimes trade secrets consist of workmen's expedients or trade tricks, which do not amount to the dignity of patentable invention. Patents should of course not be applied for in such cases.

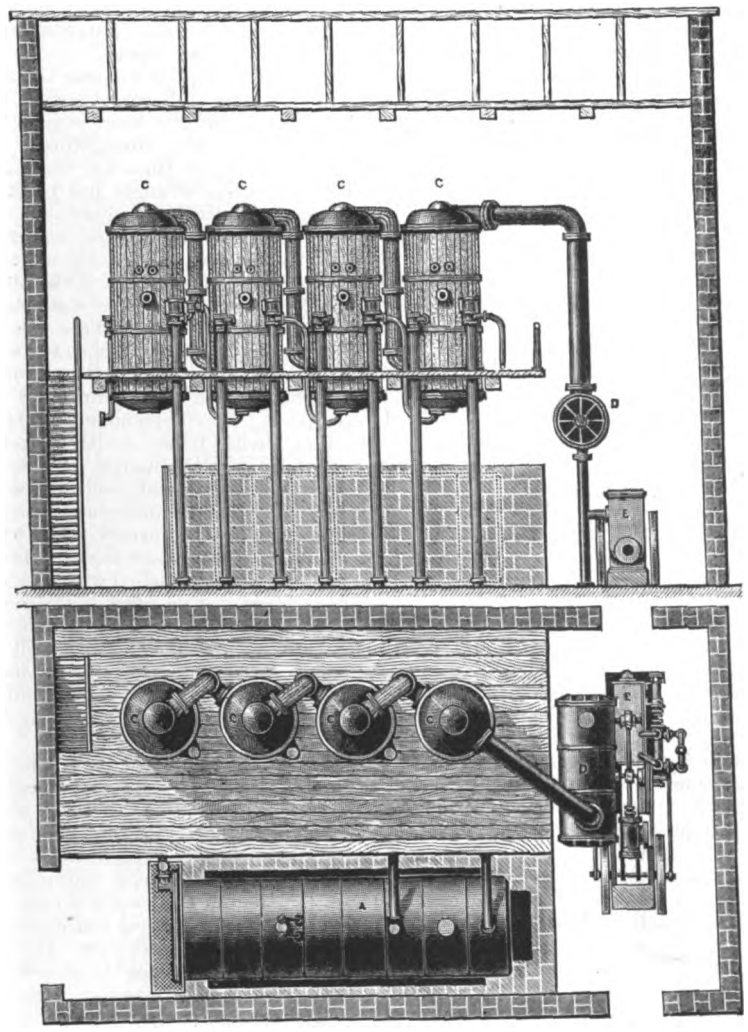
There are a great number of large works in which a stranger is not allowed to enter; on the other hand, however, there are large works where the entry of strangers is quite disregarded. Sunday afternoon is a very favourite time for visitors to go over works. The inquisitive stranger has plenty of time, little fear of being disturbed, and absolute quiet; there being no one about except, perhaps, a furnace-man who has to look to his fires on Sunday afternoons, and who has probably been the means of the intrusion.

Where there is an honest watchman, the stranger may find greater difficulty. There are some manufacturers who prefer to pay the police for extra external watching than to trust to a watchman inside. This method of robbing a man of his industry is most unfair and discreditable. It is impossible to come to any other conclusion, having regard to the clandestine way in which the information is obtained. Confidential assistants are bribed; operatives and mechanics are decoyed into the service of a rival manufacturer; works are visited against the wishes of the owners—acts which no honourable manufacturer would sanction. It may be said that these expedients are sanctioned with a view to the detection of infringements. The most casual observer will see that the object in view is different. There is a great distinction between obtaining information for the purpose of stealing another man's industry and gaining information for the purpose of detecting infringements and so securing to the patentee what the Crown has allowed him.

The English law does, to a certain extent, recognise a trade secret as a species of property. Inventors who have trade secrets are not obliged, when in the witness box, to answer questions by which such a secret would be revealed. This has been twice decided—viz., in the dye case of the Badische Anilin und Soda Fabrik *v.* Levinstein, and in the electrical case of Edison *v.* Woodhouse. The law in several European States goes much further than the English law. It is a criminal offence for a workman to disclose the secrets of his master, the penalty being fine or imprisonment.

A consideration of the foregoing remarks shows that it may occasionally be good policy for an inventor to keep an invention a trade secret. Of course, no hard-and-fast rules can be laid down; but in practice it can only be done where the inventor merely wishes to have the use of his invention himself, and where there is a reasonable chance of keeping the invention secret. The balance is greatly in favour of a patent, now that the question of subject-matter is so well defined.

PROTECTIVE CEMENTS AND WEIGHT-SAVING IN SHIP STRUCTURES.



Two elements in the structural character of most modern ships render the need for internal protective coatings even more imperative than formerly. One is the use of mild steel, and the other the carrying of water ballast in minutely divided cellular double bottoms. Extensive experiments made by various authorities have shown that unprotected steel plates corrode almost 40 per cent. faster than plates of common iron. Actual experience with steel vessels demonstrates their liability to more rapid deterioration through corrosion than iron vessels, even though equal care may have been taken to treat them with protective coatings. Moreover, the diminished thickness of the material in steel vessels, as compared with iron, is a condition imposing necessity for protective measures. This necessity is rendered still more imperative through the almost constant presence of gritty sea-water in ballast bottoms, together with the minute subdivision into compartments and the intricate cross-framing which form a distinguishing feature in modern steamers. While the almost constant presence of water ballast tends very materially to increase the rapidity of internal corrosion, the subdivision spoken of at the same time aggravates the evil, through rendering these parts less accessible for cleaning and coating.

What has been said of internal deterioration generally, as affected by the presence of water ballast, applies of course with greater force when the influences at work in specific parts of the vessel, and the consequences flowing from given kinds of cargoes, are considered. The corroding properties of gritty bilge-water in constant motion are active enough under even ordinary conditions, but with

CONSTRUCTED BY MESSRS. FAWCETT, PRESTON, & CO., LIVERPOOL.

SECTIONAL ELEVATION AND PLAN.

the increased temperature due to such cargoes as grain or wool, and especially with the air charged with acids and sulphates from wet coals, these deleterious properties are doubly potent. The top surface of the inner bottom plating, under the engines and boilers, is peculiarly liable to corrosive influences. The presence of chemically charged hot ashes in and about the stokeholds, and the general prevalence of coal dust and moisture throughout the whole machinery space, are factors in the rapidity of deterioration in this part. To allow for what has evidently come to be regarded as inevitable, careful builders adopt iron in place of steel at this part, and even increase the requisite thickness of plating. Others specially coat the plating with cement, composed of equal portions of Portland cement and sand, and in not a few cases galvanising of the plates is resorted to. Inside the cellular bottom itself, under the engines and boilers, corrosion and pitting are most serious, unless coating is resorted to at first, which, from the intricacy of framing, is most difficult of accomplishment. Even at the best influences are at work incidental to position which are most deleterious. Owing to the continual change of temperature to which the plates below the boilers are subject, through the boilers being alternately off and under steam, the heat, conducted by the plating to the contained water, gives rise to a moistness more serious and detrimental in its properties than the water itself. While conditions calculated to diminish the natural lifetime of a steamship have thus been accumulating during recent years, it is curious to consider that there has been simultaneously in progress a tendency to restrict the amount of the protective coatings applied to the insides of vessels. This tendency is directly due to the desire to reduce structural weight, and thus effect a gain in deadweight carrying capability. This desire has, in its turn, for the most part arisen from a consideration of what the substitution of mild steel for iron has effected in this direction, although the restrictions as to cargo carrying, imposed by recent load-line legislation, have also doubtless operated to render weight-saving more imperative.

The most commonly approved medium for protecting the interior surfaces of ships has long been a mixture composed of Portland cement and sand-substances—in themselves of high specific gravity, but often rendered doubly weighty by careless and ill-advised application. Attention has naturally, therefore, been directed to restricting the amount of this heavy item in ship construction to the smallest possible minimum. In many cases, however, the judicious limit has been exceeded, and the thinness of the Portland cement coating has constituted but a questionable protection to the coated surface. Although apparently impervious, cement concrete, as applied to vessels' bottoms and bilges, is more or less porous, and is especially so, of course, if the layer be of the minimum thickness, and the concrete badly compounded. Examples of the truth of this are common in house structure, as the frequent presence of damp concrete floors amply demonstrates, and instances are not wanting of vessels coated with Portland cement having been unexpectedly found to have suffered for lengthy periods through the presence of water between the cement and shell plating. The hardness and rigidity of Portland cement also renders it very liable to crack away from the plating when any strain is thrown upon it, or when subject to expansion and contraction. From these and other causes—such as hole boring, or replacement of rivets after repairs—loosening of the cement takes place, and, however limited the space actually affected may be, it will quickly be found to become a starting point for the ingress of water and resultant corrosion. This will rapidly spread, and may only be discovered by chance after most serious damage has resulted. Moreover, if applied in frosty weather, or with the least admixture of mud or grease, such as is so plentifully present in vessels while under construction, the adhesiveness of cement concrete is most seriously impaired. These and other such considerations go far to prove that, from the point of view of protective efficiency, as well as that of economy in structural weight, Portland cement, as commonly applied, is not the best coating for ship interiors. Bituminous or asphaltic substances, which preceded the use of Portland cement for such purposes by many years, but which the carelessness of manufacturers and others charged with their use allowed to get into disrepute—are of course acknowledged to be the most preferable from the point of view of first cost. Satisfactory marine cements of this class have been manufactured which only weighed about one-fourth the weight of Portland cement. Now, however, that the exigencies of ship design and construction have operated to improve its manufacture and application, lightness is not the only qualification this class of marine cement is found to be possessed of. Professor V. B. Lewes, of the Royal Naval College, Greenwich, in a paper read before the Institution of Naval Architects last spring, indicated a decided preference for bituminous coatings. Referring to the porousness of Portland cement, especially in the case of a thin coating, and of the liability this occasioned for its being permeated by liquids and gases and rapidly corroding the plating, Professor Lewes said: "It is for this reason that I consider bituminous or asphaltic varnishes, freed from any traces of acid and applied hot. or sound tough paint, preferable to cement, as, although they are not so hard, yet, if serious corrosion should be set up, it is easily discovered and stopped before much damage results; whilst, being impervious to moisture, deleterious solutions, either from the coal bunkers or cargo, would be prevented from acting upon the skin of the ship." The tendency to blister and soften under the heat of tropical climates is the principal objection still urged against the employment of bituminous cements as usually made and applied, yet the fact remains, as maintained by Professor Lewes, that cements of the bituminous order, if scientifically manufactured and properly applied, will, in the long run, prove preferable. Instances of the truth of this in actual experience are not wanting, and two may be here mentioned. The British India steamer "Kurrachee," which was built fully twenty-five years ago, in undergoing a general survey, and having her old boilers replaced by others in Calcutta, when she was about twelve years old, had all parts of her inner bottom examined, and particularly that part under the boilers. To carry this out effectually a great number of coolies were employed with chipping hammers for many days cutting out what appeared, to the correspondent reporting the circumstance, a "kind of pitch," underneath which every particle of the steamer's plates and angle-irons was found to be, not only in a perfect state of preservation, but actually retaining a "steel-coloured bloom," perfectly bright, smooth, and indicative of highest quality and condition. So long ago as December, 1867, at the request of Messrs. Brown & Simpson, shipbuilders, Dundee, Mr. William Briggs, of Arbroath Chemical Works, coated the barque "Havilah" with his marine cement—since, under the name of "Tenax," greatly improved upon—and so recently as December last, twenty-two years after application, Mr. Briggs received from Mr. P. C. Svarrer, of Fano, who sailed the vessel as master until 1888, and is now her owner, positive assurance that "the cement in the bottom is still as good as when it was put in," and that the "surveyors, in re-classing her, have also said that they have never seen the cementing better than in the case of the 'Havilah.'" No loosening of the cement has ever taken place, and it sticks well to the frames, so that "there is neither rust to be seen thereon or on the plating."

These cases afford ample justification for the very evident and growing desire of owners and builders to adopt the lighter bituminous coatings now being manufactured. Mr. Briggs, already named, and perhaps other manufacturers as well, may, by skilful attention to the preparation and special care in the application of bituminous cements, probably outrival the commonly adopted Portland mixture, at least, in those vessels designed as deadweight carriers. Already very many builders and owners are strongly disposed in favour of the lighter medium. The gain in carrying, and consequently in earning, capacity which it ensures is in itself a powerful argument in its favour, but surely every additional reason exists for its almost universal adoption when, as the result of past and recent experience in actual service, it can be proved to afford more ultimate and efficient protection, less cost of upkeep, and prolonged lifetime to a steamer.

CHAPMAN'S QUADRUPLE EVAPORATOR.

THERE has recently been fitted at the Hendon Paper Works, Sunderland, by Messrs. Fawcett, Preston, & Co., Limited, of Liverpool, one of Chapman's patent multiple effect evaporating apparatus, for which several important improvements are claimed. First, that more soda is recovered; second, increased evaporative efficiency, with reduced fuel consumption; and third, the water evaporated from the black liquor is chemically pure. The action of the apparatus is as follows:—All the waste liquors blown out of the esparto boilers to be treated are constantly fed by the donkey engine into a steam generator A (see plan above), and from these liquors all the steam required to work the apparatus is generated.

Digitized by Google

The liquor passes from the generator into the first vessel of the evaporator C C C C (see illustration), and then in succession into the second, third, and fourth vessels. The steam generated in the generator passes into the heating drum of the first vessel, the steam generated in the first vessel passing into the drum of the second vessel, as also the heated water condensed in the drum of the first vessel, and so on in the case of every vessel, the steam generated in it, as well as that condensed in its drum, pass into the drum of the succeeding vessel. There are thus five evaporations for one application of heat, in the last two evaporators the process being carried on under vacuum, produced by engine at E (see plan) in connection with surface condenser D. At the time of our visit, in the first effect the steam gauge showed 2lb. pressure, in the second zero, in the third the vacuum was 13in., and in the fourth 27in. Sight holes are provided, so that the progress of boiling the liquors can be observed, and, after five or six weeks in continuous action, there were no indications of choking of tubes. In ordinary multiple effects a regulating valve is fitted to each vessel for the purpose of adjusting the feed from one pan to the other, in order to maintain the relative difference of pressures between the vessels, corresponding to varying initial pressures and temperatures of steam and liquor supplied to the first vessel, involving a considerable amount of experience and judgment on the part of the attendant to keep the apparatus in proper working order; but in the Chapman system there is only one regulating cock for liquor and one for steam in the whole apparatus, and the temperatures and pressures in the various vessels adjust themselves to suit any fluctuations that may take place in the pressures or temperatures of the steam or liquor. Mr. Goodall, the manager of the Hendon Paper Works, to whose courtesy we are much indebted, gives the actual work performed by this new plant as follows:—200,000 gallons of black liquor of 5¾ Tw. at 160° Fahr. are reduced to 29,370 gallons of thick liquor of 46½° Tw. at 125° Fahr., ready for the roasters, by an expenditure of 20 tons 11 cwt. 3 qrs. of small coal, equivalent to an evaporation of 37lb. of water per pound of coal used, and to 10½ cwt. coal per ton of ash recovered, not including the coal used at the roaster.

BOULT'S CYLINDER-LUBRICANT TESTER.

We illustrate in the accompanying engravings, Figs. 1 and 2, an oil tester designed by Mr. W. S. Boult, Assoc.M.Inst.C.E., of Bank Buildings, Liverpool, for testing lubricants under the actual working condition—*i.e.*, at the temperature of the steam, gas, or air in which they may be used. Although many lubricants are very efficient at ordinary temperatures, they fail absolutely when submitted to the high temperatures of the steam in the present high pressure engines. The apparatus is exceedingly simple, and consists simply of a revolving journal in bearings surrounded by an oil bath, a Bunsen burner to give the required temperature, a thermometer to ascertain the temperature, a counter to register the revolutions, and a dynamometer to indicate the pressure caused by the friction. Fig. 1 is a section of the machine through the journal. This journal is an expanding one, as shown at D D, and is pressed against the bearings by means of the internal spring E, the pressure of which against D D is regulated by means of the screws B B. The journal is attached to the horizontal shaft shown in Fig. 2 by means of clutch gear, and on the shaft is the pulley, to be driven from any available power; thus the journal, with the internal spring E and regulating screws B, rotates to any required velocity. The bearings, with the oil bath C and the thermometer, hang on the journal and are free to move, the weight of these parts giving the necessary resistance between the bearing and journal. Projecting from one side of the bearing, is a small arm (Fig. 2), to the end of which is attached a chain passing to the rack and pinion of the dynamometer, the latter being simply a weighted rod acting on the principle of the ordinary letter weigher. Any resistance, therefore, which is offered to the rotating journal tends to carry the bearing round with the journal; this action is communicated by means of the lever and chain to the arm of the dynamometer and is at once indicated on the dial. The operation of testing is as follows:—The oil to be tested is carefully measured in a graduated glass pipette syringe and ejected on the journal D; the oil bath C is previously raised to the required temperature, the set-screws B are slackened so as to allow the spring E to have the full pressure, and the journal is made to rotate at about five to six hundred revolutions per minute. Observations are then taken of the number of revolutions and the indication on the dial of the dynamometer, which is graduated to indicate in pounds the absolute friction on the rubbing surfaces. The apparatus is generally run until a rise of 50 per cent. in the friction is indicated; beyond this stage the oil is practically unfit for use. The advantages of this apparatus are (1) the friction surfaces are easily maintained at a uniform temperature; (2) the pressure on the journal is constant; (3) the lubricant is completely retained on the friction surfaces; (4) the friction and the distance travelled is automatically and accurately measured. The apparatus is manufactured by Messrs. W. H. Bailey & Co., of Salford. A table of the tests made by Mr. Boult on the various lubricants which are now in the market is given above.

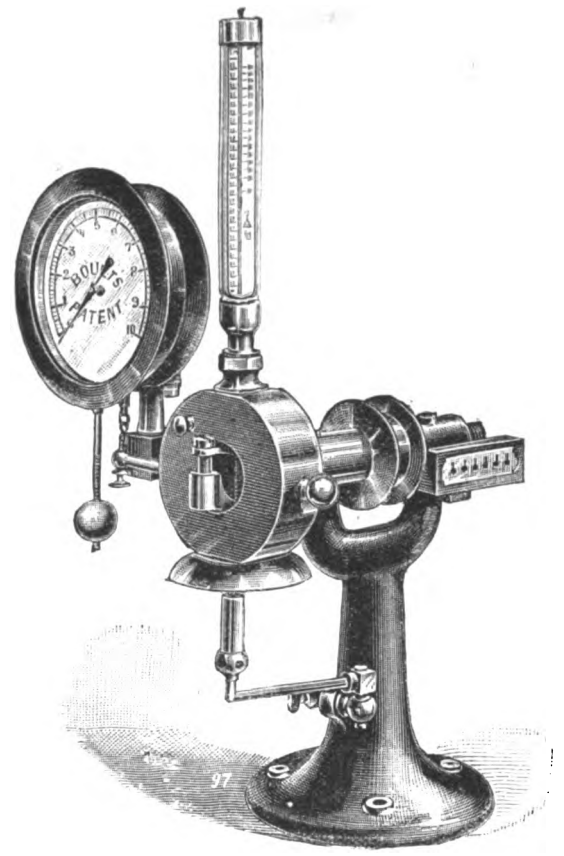

Fig. 2.

THE TUNNEL UNDER THE CLYDE.

Arrangements are now being made for beginning work at the tunnel under the River Clyde at the harbour of Glasgow, of which Messrs. Simpson & Wilson are the engineers, and Messrs. Hugh Kennedy & Sons, Partick, the contractors. Numerous proposals have been made at different times for facilitating cross-river communication for vehicles and passengers, including improved ferry-boats, overhead bridges, and a tunnel, or rather several tunnels. The latter has been pushed on entirely by private enterprise, while the two former have generally had a certain amount of official patronage. In the meantime the official schemes seem to have been withdrawn until the results of the private enterprise are seen, another example which shows how desirable it is to allow ingenuity and energy to have free scope and not to be damped by official routine. There will be three tunnels laid alongside each other, with only 2ft. between them, and they will be formed of cast iron segments of 16ft. diameter. The inner tunnel will be for foot passengers, and the two outer ones for vehicles. At their highest point the tunnels will be 15ft. below the bed of the river, and 35ft. and 46ft. respectively below low and high water levels. The shaft on the north side of the river is to be at a point about 400ft. west of Finnieston Street, and about 60 yards from the quay wall. It will be 80ft. in diameter, and 72ft. in depth. The one on the south side will be very similar, and each will be provided with hydraulic lifts. The central tunnel for passengers will, at both ends, rise by a stiff gradient to within a few feet of the surface, thus obviating the necessity for hoists, against which there seems to be a prejudice in the public mind. The whole arrangement will be lighted by electricity, and seems well designed to meet the objects in view, and as it is proposed to make the charges light, no doubt it will be largely taken advantage of.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 153.)

PARIS, 11th February, 1890.

COAL.—Coal continues to rise steadily in price. Fortunately the winter has been exceptionally mild; had it been otherwise the scarcity of fuel would have occasioned a serious disturbance of the equilibrium of trade. As it is, the coal mining industry is in an abnormal condition. To increase the output the colliery proprietors are engaging agricultural labourers as putters and drivers. Even under this extra pressure the production falls short of the demand. The prices paid are above what the most sanguine ventured to hope for six months ago. Briquettes, which a short time ago could be bought for 8s. 6d. a ton, now sell readily at 24s. This form of fuel is in specially strong demand. It has been steadily in favour in the last two years, and it appears likely that its manufacture will constitute a very important branch of the coal mining industry in the near future. Experiments made at the Anzin collieries have shown that when properly made these blocks will keep without appreciable deterioration for at least ten years.

IRON.—The amount of business transacted in the market of Paris just now is small, consumers limiting their purchases to the bare needs of the moment. But thanks to greater activity in the provincial markets prices are firmly maintained. There are this week no new features to report in the business of the provinces; but the tendencies of the past few weeks continue, and even manifest themselves more distinctly in some districts, notably in the Loire-et-Centre, where a strongly marked upward movement is in progress. The situation generally is strong and the prospect cheering.

CHILDREN'S LABOUR IN FACTORIES.—The commission appointed to examine the Bill passed by the Senate relating to the labour of women and children in factories and workshops has refused to adopt the wording of the Bill as it stands, and it has decided to open a Parliamentary inquiry concerning the regulation of night work for women in various industrial establishments, and also to take the opinion of the Academy of Medicine on the hygienic question.

EXHIBITION OF AGRICULTURAL MACHINERY.—The annual Agricultural Exhibition is now being held in the Palais de l'Industrie. In the machinery section there are 4,344 exhibitors, who have brought together a very complete collection, including some machines and implements of new design. The Palais is just now well worth a visit from foreigners who may be staying in the French capital.

ELECTRIC LIGHT IN WARFARE.—Some interesting experiments have been made at Toulon to ascertain the accuracy of aim when the electric light is used for night attacks. A large gun—19 c.m. calibre—was mounted on a revolving platform, which also carried an electric projector. The mark to be hit was from 3 to 4 kilometres distant, and the only light was that of the projector. It was found that the gun could be discharged with as great rapidity and precision as was attained in daylight.

THE INTERNATIONAL SOCIETY OF ELECTRICIANS.—This society met at Paris on the 5th inst. M. Hippolyte Fontaine read an exhaustive paper on the electric lighting at the late Exhibition, and compared the practical working of the various systems. M. Violet described a new arrangement for reading the indications of mirror galvanometers, by means of which the space occupied is reduced and the operations simplified.

BERLIN, 10th February, 1890.

FLAX AND YARNS.—The Trautenau market for linen yarns is somewhat less animated. The attendance is good, but buyers seek to deal at lower rates, and, as spinners are firm in their demands, business is limited to the strict necessities of the moment. The finer numbers of linen yarns and the coarser numbers of tow yarns are most inquired after. At Bielefeld the market is more active, and a large amount of business in "futures" is being transacted.

THE GLASS TRADE.—The makers of table and lamp glass have formed themselves into a syndicate, and have made financial arrangements with a Berlin banking house with a view to facilitate the export trade.

THE SOAP TRADE.—The prices of soft soap were, in the early part of last year, so depressed by excessive competition that the margin for profit vanished altogether. In the months of June and July a rise of from 2s. 6d. to 3s. per cwt. in the price of linseed oil enabled the makers to obtain an advance which the market readily accepted. But within the last few months potash has risen about 20 per cent. in value, and coal has advanced in a much larger proportion. The soap makers have therefore determined to announce immediately another considerable advance in the prices of their produce, the present rates having again become unremunerative.

SHIP CARPENTERS' WAGES.—The strike of ship carpenters at Hamburg has ended in the concession to the men of the following rates of wages:—From March 1st to October 27th, 0·45 mark (5·4d.) an hour, and from October 28th to the end of February, 0·48 mark (5¾d.).

CHEMNITZ KNITTED GOODS TRADE.—The Chemnitz knitted goods trade has greatly fallen off of late, and manufacturers now are not able to keep their hands employed. Only the cheaper kinds of goods are in demand. The trade with England, formerly so brisk, is greatly depressed. To recover some of this trade, manufacturers are seeking to deal directly with the retail sellers.

RAILWAY ROLLING STOCK.—The lowest tender for the recent contract for the construction of 250 goods waggons for the Warsaw and Vienna Railway was made by the firm of Van der Zypen, of Deutz, near Cologne. Notwithstanding the duty of 180 roubles per axle, they were able to underbid the Warsaw makers by 15 per cent.

ELECTRIC LIGHTING.—The municipal authorities of Cassel have decided to light that town by electricity.

THE DESPATCH VESSEL "METEOR."—The fitting up of the despatch vessel "Meteor," launched from the slips at Kiel the other day, is being pushed on with all possible speed. At the present moment her engines are being put in. These are extraordinarily powerful relatively to the size of the ship. They are triple-expansion engines of the vertical type. The boilers are of the locomotive type, and are four in number. With these engines, which are capable of developing 5,000 i.h.p., the vessel is expected to make from 22 to 24 knots an hour. Her displacement is 950 tons.

A SIBERIAN RAILWAY.—The Government of Russia have decided on building a railway right across Siberia, and plans have been drawn up for its construction. The line is to be 4,300 miles long, is to take ten years in building, and is to cost 250,000,000 roubles. This is a comparatively low figure, but the quality of the work will be sacrificed for simplicity of construction.

VIENNA, 10th February, 1890.

THE COAL MARKET.—On account of the weather the demand for coals on the Vienna market decreased last week, but the stock of the Northern Railway Coal Depôt, which is usually high, diminished away, and now scarcely amounts to 300 waggons. The colliery owners are fearing a strike, and they are very busy for this reason to produce the necessary quantities for industrial purposes. This circumstance presumably will be followed by a general increase of prices. The Nordböhmische Kohlengewerkschaft, in Brux, has issued its shares, of a total value of 4,200,000fl., and has brought a great number of Northern Bohemian collieries for the price of 3,800,000fl.

THE IRON MARKET.—The decrease of the prices of warrants at Glasgow and Middlesbrough for the moment checked our market; but as all branches have such a large number of orders on hand, the old firmness soon re-entered, and now the tendency is again towards improvement. Bohemian and Styrian works have declared an increase in the price of wire-nail and foundry work. The locomotive manufactory of Wiener-Neustadt has received an order from the Bustehrad Railway for fifteen locomotives. The extraordinarily good business which has been done this year by the locomotive and waggon builders has had its effect already, for a large establishment for waggon and machine construction is to be erected near Brunn by Messrs. Lederer & Porges, of Koenigsfeld. The new establishment will give employment to some hundred hands.

RAILWAY TRAFFIC IN AUSTRIA DURING 1889.—The official reports on this matter, issued a few days ago, show that the total income of the Austrian railways last year was greater than in 1888, but the takings per kilometre were the same. The total receipts amounted to 280 million florins, being an increase of 10·4 million florins over 1888; but the total length of our railways was 25,561 kilometres last year and 24,707 kilometres in 1888. In both cases the relative receipt was the same—*i.e.*, 10,912fl. per kilometre.

SHIPS OF WAR.—The naval officials of Austria some time ago ordered a cruiser from an English firm of shipbuilders, and a commission went to England a week or two ago to test it. The trial trip was so unsatisfactory, and the construction was considered so faulty, that the commissioners have recommended the Imperial Government not to accept the vessel. This course has been followed by the Government, and they have definitely declined to take over the cruiser.

THE LABOUR QUESTION.—Dr. Singer, of the Vienna University, has been gathering statistics as to female labour in the five principal countries of Western Europe. From these statistics it appears that 20,000,000 women are employed regularly in factories, shops, &c.; of this number 4½ millions are in England, 3¾ millions in France, 3½ millions in Italy, 5 millions in Germany, and 3½ millions in Austria.

BRUSSELS, 11th February, 1890.

THE COAL MARKET.—The coal market is gradually resuming its customary appearance, and things are settling down again after the strike. Several of the harder sorts of coal, such as anthracite, when mixed with coke, are now being used in blast furnaces. In anticipation of the approach of the season for burning bricks the association of producers of Charleroi and Basse Sambre have fixed 15fr. as a basis price for close-burning coal. The domestic sorts do not share the same briskness as manufacturing qualities on account of the general mildness of the weather.

THE IRON MARKET.—The lowering of the prices of English irons has caused some uncertainty in the Belgian markets, and there is a slight halt in the sale of pig. Some of the makers have decreased their prices, but the syndicate of Luxembourg producers have sold all their iron, and have no need to follow the Belgian lead. The Etablissements Nicaise and Deleuve have obtained the contracts for the construction of the coal stations in the Netherland Indies The contracts for the 3,500 waggons for the German railways have been awarded mostly to Belgian makers, who quoted a lower price than German manufacturers.

THE TRADE OF ANTWERP.—The trade of Antwerp is seriously declining. In 1889 there was a decrease in the tonnage of 467 tons, while in the whole of the eight years ending with 1888 there was only an increase of 900,000 tons; in 1880 the total was 3,063,829 tons; and in 1888, 3,920,714 tons. Rotterdam, on the other hand, is making remarkable progress. During the nine years ending with 1889 her trade sprang from 1,681,690 tons to 2,721,479 tons; while the trade of Antwerp only increased in the same period from 2,766,806 tons to 4,355,511 tons. The tonnage entering Antwerp in 1880 exceeded the combined trade of Rotterdam and Amsterdam by 400,000 tons, while now it is 150,000 less. Other towns also have been striving to deprive Antwerp of her trade, notably Bremen, Flushing, Dunkirk, Marseilles, and Bordeaux. In 1880 Antwerp had at her command the entire transit traffic between South and East Germany, Northern and Eastern France, Switzerland, Austria, England, and America; but it is now being distributed between the ports above named. It appears that excessive dues have driven the shipping from Antwerp Harbour. For example, ships of 1,800 tons have to pay in the Scheldt taxes to the amount of 400fr., which they do not have to pay either at Hamburg or Rotterdam.

DÜSSELDORF, 11th February, 1890.

COAL.—The strained relations between the colliers and their employers keeps the market in a sensitive state. Much interest attaches to to-morrow's tendering for 100,000 of locomotive coal for the Bavarian State railways. The price is likely to be 20s. on railway at Gustavsburg. The latest list of prices issued by the "Coal Club" contains the following quotations:—Gas coal, 16s. to 18s.; free burning coal, rough, 12s. 6d. to 13s. 6d.; large, 15s. 6d. to 16s. 6d.; washed nuts, 14s. to 16s.; dry burning coal, rough, 12s. 6d. to 13s.; large, 16s. to 19s.; nuts, 17s. to 20s.; small, 7s. to 8s., foundry coke, 29s. to 31s.; blast furnace coke, 28s. 6d. to 31s.; briquettes, 16s. to 18s. a ton, at the pits or ovens.

IRON.—The iron market has assumed a quieter aspect. The current of business is, however, steady, and prices are very firm. The firmness is due rather to the prospect of higher prices for raw materials than to any indications of a heavier demand for iron. The Exchange meeting on the 6th inst. was well attended, but buyers confined their operations to small transactions. The members of the Rhenish-Westphalian pig iron syndicate met at Cologne last week, and agreed to continue the present minimum prices, production being below consumption, stocks practically exhausted, and the prospects of the coal trade uncertain. A resolution was passed continuing the common sales bureau for forge pig till the end of 1891. The first contract for steel rails tendered for in the present year was for 5,400 tons for the Erfurt Railway. Rhenish-Westphalian manufacturers alone tendered, the lowest offer being 165s. a ton at works by Krupp, of Essen. The highest tender was 170s. Business in rolled wire is unsatisfactory. For drawn wire there is a fairly good demand.

FUSION OF POWDER WORKS.—A scheme for the fusion of the Rottweil and Hamburg and the Rhenish-Westphalian Gunpowder Manufacturing Companies is under consideration. An application is to be made for a quotation of the shares of the latter company on the Berlin Stock Exchange.

THE HENSCHEL LOCOMOTIVE WORKS.—At the Henschel Locomotive Works at Cassel, the three-thousandth locomotive was completed on the 1st inst. To celebrate the event a sum of £500 was distributed among the workmen, and a fund was established for the erection of fifty workmen's cottages.

PRICE OF PAPER.—At the meeting of the paper makers of the West of Germany, held at Cologne last week, it was decided, on account of the increased cost of coal, chemicals, and raw materials, to advance the prices of paper in a corresponding degree. A special union of the manufacturers was then formed to protect their common interest. Nearly all those present joined this association.

LILLE, 11th February, 1890.

IRON.—There is considerable activity in the iron market of this district, and a fair prospect of brisk trade for many months to come. Manufacturers have sufficient work in hand to keep them going till June, and fresh orders come to hand to keep their order books filled well ahead. The following are the prices now current:—Bars, 160s.; joists, from 164s. to 168s.; common plates, 200s. a ton. These advanced rates are readily paid.

TEXTILE MANUFACTURES.—Though the degree of activity in the market for linen goods is somewhat less than it was a week ago, the turnover for the last week is satisfactory in quantity, and the current of business is strong, considerably above the average for this season. Paris houses are buying largely, but provincial consumers hesitate. Prices show no important change, but the market is very firm. There is nothing new to report of the woollen goods trade at Roubaix. Business continues brisk, and the outlook is encouraging. The market for raw wool has, however, given way a little. A further decline is probable.

FLAX AND YARNS.—The flax market is moderately active. Walloons from Douai and Bergues sell readily. Prices remain unchanged for common qualities, but the better sorts are much sought after, and are higher in price.

Digitized by Google

More business is being done in Russian flax. There is not much doing in tows. Business in yarns is still restricted to the needs of the moment. Sales are effected with difficulty. No concessions in price, however, are made. The demand for jute yarns continues brisk, but the coarser sorts are less inquired after.

AMSTERDAM, 10th February, 1890.

The Proposed Maritime Harbour at Scheveningen.—Having found that this scheme, which virtually will make the Hague a seaport town, has excited some interest in England, I append the following particulars:—A Royal Commission having recommended certain works to carry out the plan, a small Anglo-Dutch syndicate, at whose head are two gentlemen named Steers and Clifford, has elaborated a project in accordance with that recommendation. The new maritime harbour is to be created at the mouth of the fresh-water canal, where a pier for steamers will be constructed, having connection with the Holland Steam Tramway, and being protected by two moles projecting into the sea 950 metres. These two moles will form an entrance from the sea 110 metres wide. Next to the maritime harbour there will be the mercantile harbour, with extensive quay walls, warehouses, &c., and to the north of that the harbour for fishing craft, providing room for some 300 smacks, Scheveningen being one of the centres of the Dutch fishing trade. These plans have been approved, it is stated, by an eminent English engineer, whose name does not transpire, and are also sanctioned by the Government engineers.

The Goldfields of Guiana.—It is stated that Holland has withdrawn her reserves, to which I alluded in my last letter, and that, consequently, the Czar of Russia will be asked once more to act as high arbitrator in the dispute between the Dutch and French Governments.

The Fisheries in the Maas.—Holland has invited the powers that are with her interested in the fisheries of the Maas to meet in a conference for the settlement of the long-standing fishery questions. The delegates of France, Germany, Belgium, and Holland will assemble at the Hague in June next.

The New Tin Island in East India. The Singkep Tin Company, concessionaire of the island of Singkep, has raised its capital from 1,250,000 to 1,500,000 guilders—say, £125,000—to ensure the regular working of the tin mines. Singkep promises to become a formidable rival to its great tin-producing neighbours, Banca and Blitong. Its size is about 50,000 hectares—say, 123,550 acres—and it belongs, as I have already stated, to the Lingga Islands, a group off the east coast of Sumatra, and formerly belonging to Johore and Malacca. The tin mines of Singkep are supposed to be of great antiquity. They were hitherto worked by the native Sultan, who is a vassal of Holland. He exported the ore to Muntok, the capital of Banca, or to Singapore, but Singkep tin was not known by itself in the European market, being sold for Banca or Blitong.

Export of Hungarian Produce and Commodities to Holland.—The Market Halls Company of Amsterdam is negotiating with the Hungarian Government for the regular export of Hungarian products and commodities to Holland, which are to be retailed by the above-named company. Its director has left Amsterdam for Budapest, at the request of the Minister of Commerce there, to settle the details of this scheme. In connection therewith, an important report has just been laid before the Municipal Council of Amsterdam by the commission appointed for the purpose of studying the means of increasing the transit trade of the Dutch capital. The commission suggests the appointment of a special committee to work out the details of a project which is contained in the above-mentioned report, and which includes the following main features:—The establishment of important quays, warehouses, and other facilities for international commerce around the existing ones on the Y, a general lowering and equalisation of all dues, a better system of railway accommodation, and the placing of the whole of the maritime harbour under the management of an independent board, in the English fashion. The same special committee will also have to study a gigantic scheme of a bridge across the Y.

Cotton "Futures" at Amsterdam.—Dealings in cotton "futures" at Amsterdam are to be centralised through the medium of the Produce Clearing House there, as from the 1st March next.

New Industrial Company.—At Amsterdam the Javasche Cultuurmaatschappy has been brought out, with a capital of 2½ million guilders (a little over £200,000), under the management of Mr. N. P. Van der Berg, the late chairman of the Java Bank. The new company proposes to buy coffee and other estates in Java, also several sugar factories, for the purpose of working them, and engaging in produce trade generally.

COPENHAGEN, 8th February, 1890.

Wood Pulp.—The manufactory for chemical wood pulp at Delaryd, Sweden, is a very important concern. By several years' careful and patient experimental working the process which is adopted here has been perfected, so that the works now turn out wood pulp of exceptionally good quality. The fibres are long and strong, and the Delaryd wood pulp is extensively used in various countries for mixing with wood pulp of inferior quality. The method of working at this establishment is to some extent a secret, which it is no wonder they want to keep as long as possible in these days of excessive competition within the wood pulp industry. The establishment employs about a thousand hands, in addition to which a number of other persons obtain employment through it. Everything is as practically arranged as possible. The works have their own railway, a somewhat modified style of the Decauville system, over which it seems to possess several advantages, inasmuch as it is understood to be both cheaper, faster, and more durable than the other. A Swedish locomotive, specially constructed for this line, costs only about one-third of what one for the Decauville railway costs, and yet the Swedish locomotive is simpler, stronger, and handier for its purpose than the other, and has four sets of wheels. The railway at Delaryd will be extended this year with some five kilometres. The following particulars of the Delaryd railway may be of interest:—The gauge is 650 millimetres, weight of rails 7 kilogs. per metre, greatest rise 1 in 25. They have two locomotives, both made at the Delaryd Engineering Works—a smaller four-coupled three tons, and a larger eight-coupled six tons. The latter pulls 60,000 kilogs., with a rise of 1 in 50; the usual speed is 18–20 kilometres per hour. The rolling stock consists of twenty trucks for wood and peat, and the capacity of the line is said to be marvellously large. No accidents have ever happened there. The Helga River, at the borders of which the works are located, not only supplies the greater part of the power for the various machinery, but also for the electric lighting of the whole establishment. The electric lighting is also exceptionally well arranged, and care has been taken that there is ample power. A great deal of money is saved annually by the works making and using their own peat, instead of coal. While the latter would cost about 50,000kr. annually, the former only entails an expenditure of some 20,000kr., which is nearly all paid in wages, another benefit to the neighbourhood. About 350 men are engaged in making peat about 100 days annually, assisted by six steam engines of 60 h.p., a water wheel, and 15 peat machines. The annual production of peat amounts to ten million pieces, and the supplies seem to be almost inexhaustible. The demand for Delaryd wood pulp is so great that it has been on the tapis to work also on the Sundays, but out of regard for the men this plan has not been carried into effect. The annual production is at present about 2,500,000 kilograms chemical wood pulp, bleached and unbleached, which finds a ready market in England, France, and America, and there is no doubt that the works are capable of still further extension.

MADRID, 10th February, 1890.

Asturian Coals.—The price of coals in Asturias has been raised in consequence of the demand that has sprung up on account of the rise in England. At the present moment gas coals are selling at about 12s. on waggon. The gas works of Madrid save the whole freight from England and the 1s. import duty by buying Spanish coals, but they cannot get a regular supply to the extent they require. As the gas works of Madrid sell their coke at a high price and never have any in stock, their retorts are heated by some very inferior native coal. They do not sell their tar well nor use the ammonia liquor.

Customs Reform.—The commission appointed to study the customs reforms and to examine the question of treaties in connection with the approaching end of most of them in 1892, have fixed the 27th inst. to receive written information. As to the English treaty it will not make any difference at all whether it is renewed or not, and trade will go all the same. As to the French treaties great fears are shown that our neighbours will refuse a renewal. Such an occurrence might be followed by some advantage to Spain.

NEW YORK, 1st February, 1890.

Elevated Railroads.—The report of the elevated railroads of New York for the year 1889 has just been issued. It shows that 182,413,987 passengers have been carried last year without one being injured through the carelessness or other fault of the management. The same claim has been made for previous years, and as the total number of passengers carried since the lines were erected has been 1,251,967,720, it is quite a satisfactory showing.

Bursting of Glass Furnaces.—At the tank factory of the Chambers-McKee Company, at Jeannette, Pa., two of the furnaces burst, temporarily suspending the oporation of the plant. This plant is the first of its kind in America, and has become famous through the importation of English glass blowers to operate it. The report says that the natural gas had been turned on too strong, and the chemicals not properly attended to, when two out of the three furnaces burst, about 135 tons of glass being lost. Eight hundred men are temporarily idle, as it will take some time to repair the damage.

River and Harbour Improvements.—The Senate Committee has decided to report several Bills making appropriation for carrying on some of the larger works without waiting for the regular Bill. An appropriation of $5,000,000 for the St. Mary's River and Hay Lake project, known as the "Soo" Canal, will be made, and one of $500,000 for the improvement of the Columbia River in Oregon. General Comstock and Major Ernst, of the Engineer Corps, were given a hearing on a Bill for a deep-water harbour at Galveston, Texas. Galveston, in their opinion, was the best place on the Gulf coast, west of New Orleans, for a deep water harbour. The demands of the great South-West required that a harbour should be established on the Texas coast, to give a convenient and comparatively cheap outlet for the cattle, grain, and other products of that section.

Profit Sharing.—The operatives of the Bourne Mill, Fall River, Mass., were last week paid the first dividends on mill earnings ever received by operatives in an American cotton factory. The plan was adopted last spring, and was to divide a sum not less than 6 per cent. of the total amount paid in dividends to stockholders for six months beginning July 1st, the amount paid to each operative being in proportion to the total wages earned. The dividends paid to stockholders amounted to $32,000, and $2,000 was paid to the operatives, which was 3¼ per cent. of the total wages earned by each. Out of 483 operatives employed 401 were entitled to a share in the profits. The Bourne Mill pays the same wages as other mills, and the system of profit sharing has worked such good results that it will be continued for another six months.

Naval Affairs.—The Senate Naval Committee has put itself on record as favouring very large appropriations toward rebuilding the Navy. The Committee reported favourably on a Bill to build eight battle-ships of 7,500 to 10,000 tons, two armoured coast defence vessels, three gunboats, and five first-class torpedo boats. These will cost in the neighbourhood of $50,000,000, and an appropriation of $7,000,000 is made to begin with. Some of the members of the Committee dissent from the report, and, as stated in my last letter, there is hardly a possibility of any such extended increase in the Navy being authorised by this Congress. The United States' sea-going torpedo boat No. 1 was launched, and the Herreshoff Manufacturing Company's works on the 23rd inst. The fires were started as the vessel started into the water. Steam was raised in 32 minutes for running her auxiliary machinery.

Tube Works Removal.—The extensive Tyler Tube Works, of South Boston, Mass., are to be removed to Washington, Pa., and the engineer of the company is at work on the plans for the new mills, which will be considerably more extensive than the present works. The reason for the change is that fuel and raw materials cost too much for transportation to Boston, leaving little or no profit in the business.

Pennsylvania Railroad.—The statement for December and the year 1889 has attracted general attention. The net increase in earnings is equal to nearly 6 per cent. on the stock, a remarkable result when the interruption to traffic and the loss of property at Johnstown are taken into consideration. The statements so far made are only preliminary. There is little doubt that the final figures will show that the gross earnings of the Pennsylvania system and auxiliary roads during 1889 were $130,000,000. The increase in the company's business has been general in all the departments, and, notwithstanding the depression in the coal trade, the fuel traffic of the company was greater than in 1888.

The Coal Trade.—The anthracite trade continues very dull, and it is almost impossible to sell the domestic sizes. The demand for manufacturing sizes is all that could be expected. The restriction now going on does not help the trade much, and a further decrease in the output will be necessary if the weather is unfavourable in the east during the next two months. In the west the weather has been seasonable, and it is now colder in this section than at any previous time during the winter, and this must increase consumption if it continues. The shipments for the past week have amounted to 490,000 tons, a falling off of about 140,000 tons as compared with last year. Bituminous coal is active, and prices are easier.

Colorado Coal.—The advance in Colorado coal during the past few weeks has been equal to 15 per cent. Under the new management the business of the company is rapidly increasing. In the coal and coke departments the increase in net earnings has been from $8,000 in September to $35,000 in December. The real estate developments at Pueblo being particularly advantageous, the company having sold $150,000 worth in one day. There is a larger and more profitable market for pig iron, and the company will shortly erect two new blast furnaces. The steel rail plant promises to add largely to the net income, as the output can readily be all sold to Colorado roads, and having its own raw materials for Colorado business has an advantage over Chicago of from $6 to $7 per ton. The pits will soon be at work, and will turn out about 50 tons per day.

The Iron and Steel Trade.—Business has not improved during the past week, and evidences of weakening are becoming stronger. Steel is holding its own, but pig iron and some lines of manufactured iron are weaker. There is a great deal of business being done, but there is an immense output, and the market is in danger of too much to sell. In pig iron the tone is decidedly weaker, although prices are nominally unchanged. Buyers can, however, place their orders to better advantage than for some time past. In manufactured iron there is nothing encouraging in the outlook. The demand is slow, and manufacturers still complain of delay in specifications, so that while some of the mills have all the orders they desire they are running short of work. Nominally prices are unchanged, but on any good order concessions of perhaps a dollar per ton can be obtained. Prices are at about 2c. for best refined bars, 2·35c. for plates and angles, with the usual advance for steel. There is a fair demand for steel billets, which are from $38·25 to $39 per ton. Rails are quoted at $36, but on desirable orders concessions are said to have been given lately. Mills are well supplied with orders, and the general outlook is satisfactory.

THE STEAM ENGINE INDICATOR.

At a meeting of the Owens College Engineering Society, Manchester, held on the 4th inst., Mr. C. F. Budenberg, M.Sc., read a paper on "The Steam Engine Indicator."

In commencing his paper Mr. Budenberg first referred to the work done by Watt, and remarked that as made by him the indicator was a remarkably perfect instrument, the correction of its errors having been a somewhat difficult task. The defects arising from the long spring used by Watt when high speeds were obtained were first overcome by Mr. Richards in the well-known instrument bearing his name. A description of the Richards indicator was then given, and its chief features dealt with. The author said that the different springs supplied with the instrument were identified in terms of their displacement in fractions of an inch under a pressure on the piston of 1lb. per square inch, or a direct load of ½lb., the springs being numbered accordingly. The scales were usually multiples of 4 or 8, so as to allow of the use of an ordinary inch scale, and the divisions were uniform throughout on the assumption that the deflection of the spring throughout the scale is directly proportionate to the load. This was not strictly true, and it would be more accurate to divide each scale separately from the spring instead of forcing the spring into a predetermined scale. The error was not large, being, as determined by Professor Reynolds and Mr. Brightmore, about one per cent. in ordinary good springs. Mr. Budenberg then described the manner of testing and adjusting the springs, and advocated their construction from double coils, as the risk of breakage was diminished and the pressure of the coil balanced. The diagrams obtained by the Richards indicator formed a fairly satisfactory record, and the limits of speed at which it can be employed were determined by Professor Reynolds, who showed that to be free from oscillation the speed must not exceed 69, 105, and 155 revolutions per minute when using the 1/20th, 1/50th, and 1/100th springs respectively. The object of recent improvements had been to reduce the inertia of the parallel motion so as to obviate the oscillations of the pencil and enable the instrument to be used at the high speeds now common. A description of the Thompson indicator was then given, and it was pointed out that the parallel motion used had the advantages of being lighter, more stable, and more compact, than the Richards. The parts having a large range of motion were reduced in weight to a minimum, and the heavier members had a comparatively small motion. The rods were all in one central plane and with one exception were long, the number of joints was reduced, the joints were made with large bearing surfaces, and the angle of movement was comparatively small. The objections existing against Richards, arising from the easy flexure of the cross-bar by the pressure of the pencil, the sluggishness arising from wear, and the oblique pressure on the small link coupling the piston rod to the horizontal bar, were entirely obviated by the Thompson indicator. The coupling of the horizontal rod and piston in the latter was effected by a connecting rod attached to the piston by a ball joint provided with means of adjustment. The cock was made with a passage ½in. diameter instead of ⅜in. as in the Richards. The piston movement was multiplied in the proportion of one to four, the diagram produced being 3in. in height. A smaller size of the Thompson was made for special purposes, which weighed only 5lb. instead of 11lb. in the larger size. The Crosby indicator was of American origin, and was—although slightly varied in detail—similar in principle to the Thompson. The stroke of the piston was ⅜in., being multiplied six times, giving a diagram 2¼in. high. The links were made short, and the angle of motion was large. In consequence the friction and wear were increased, and this, owing to the large multiplication, was a very serious matter. Adjusting screws were provided to take up the wear, but this appeared to be too delicate for ordinary practice. This was the chief objection to the Crosby indicator, which, while a very efficient instrument for scientific observation, and excellently constructed, was so lightly made as to be easily damaged and made inaccurate. At high speeds it was also affected by the vibration of the engine. Mr. Budenberg then briefly referred to the Kenyon indicator, which, he thought, was objectionable for steam-engine work, but Professor Unwin had used it successfully for hydraulic testing. The Tabor indicator, like the Crosby, was of American origin. It differed from the Thompson in the fact that the pencil rod was constrained by guiding it in a curved slot provided in a stationary plate, the curve being nearly a true circle of an inch radius. The friction naturally arising from such an arrangement was obviated by the use of a roller on a pin in the sliding bar. By this arrangement the weight of the parallel motion was reduced, the multiplication being in the proportion of one to five, the motion of the pencil being 3¼in. and the stroke of the piston ·65in.

Mr. Budenberg then proceeded to deal with the method of taking indications, remarking that variations arose in diagrams taken alternately from each end of the cylinder owing to the variations in the work of the engine during different strokes. Only by simultaneous indications at each end could absolutely accurate results be obtained, and a double indicator was described which was practically a combination of two acting upon the pencil simultaneously. Two pistons were fixed upon the same spindle, and were respectively subject to the pressures on both sides of the engine piston. One spring only was used, being compressed upwards or downwards according to the direction of the resultant pressure on the

engine piston. The diagram was, therefore, partly above and partly below the atmospheric line, as shown in Fig. 1; its distance from the latter represented the actual resultant pressure on the piston rod, and its whole area represented the actual work during one revolution. If necessary, diagrams could be taken from each end alternately, these being shown by the dotted lines in Fig 1. A peculiarity of the double instrument was that its indications were independent of the barometric pressure, the piston rod being equilibrated for it. The pipes and cocks must be of large size, so as to avoid any throttling, and if this was done, the errors of which so much had been written were entirely avoided. After dealing with the essentials of an indicator and of accurate observations, the author summarised the results of Professor Reynolds' paper before the Institution of Civil Engineers in 1885. Dealing with the causes of errors therein laid down, he said that the error caused by the oscillations depended not merely on their magnitude but chiefly on the smallness of their number in a revolution, and gave some figures showing the limiting speed for various springs in the Richards and Thompson indicators. One of the most remarkable of the results of Professor Reynolds' researches was to show that the effect on the area of the diagram of the friction of the drum was considerable, a reduction of from 10 to 20 per cent. being frequently produced. The manner in which the variation of the tension of the drum spring during one revolution was shown diagrammatically (Fig. 2); the vertical ordinates represented the tension on the cord due to this cause at all points of the stroke. The effect of the inertia of the drum was more complex, and might be represented as in Fig. 3, the vertical ordinates representing tension of the cord due to the inertia of the drum. Starting at zero, the tension was reduced during the first half of the stroke, the degree of reduction decreasing until about quarter-stroke, and increasing until mid-stroke. The inertia increased the tension during the latter half, the action being reversed during the out-stroke, as shown in the diagram. These two diagrams were combined in Fig. 4, which represented the variations of the resultant tension on the cord due to these two causes. The effect of the friction of the drum was to produce a force always opposing the motion of the drum, and therefore increasing the tension during the outward stroke, and reducing it during the inward stroke. At the end of the stroke the direction of this force changed suddenly, this effect being shown in Fig. 4, which was introduced on the diagram already made for the spring variation and inertia. If y = amount of stretch of the cord per pound of tension F = force in pounds necessary to overcome the tension of the string, then y F would represent the stretch due to the friction, and it was found that the least amount of this was $\frac{1}{40}$in. per foot length of cord. At the commencement of the stroke, the tension changed suddenly to 2 F, and the drum would remain stationary, while the engine piston moved through a distance equivalent to 2 Fy of the drum motion. If, therefore, the steam admission took place instantaneously at the commencement of the stroke, the effect considered would cause a displacement of the admission line of 2 Fy, the diagram being proportionately shortened. This was found to amount to 20 per cent. with an ordinary cord, but was reduced when a wire was employed. A different length of cord being used at the two ends of the cylinder, the effect was greater in the diagram from the back than from the front end of the cylinder. Fig. 5 is a combined diagram of the effects of the varying tension of the drum spring, inertia, and friction.
